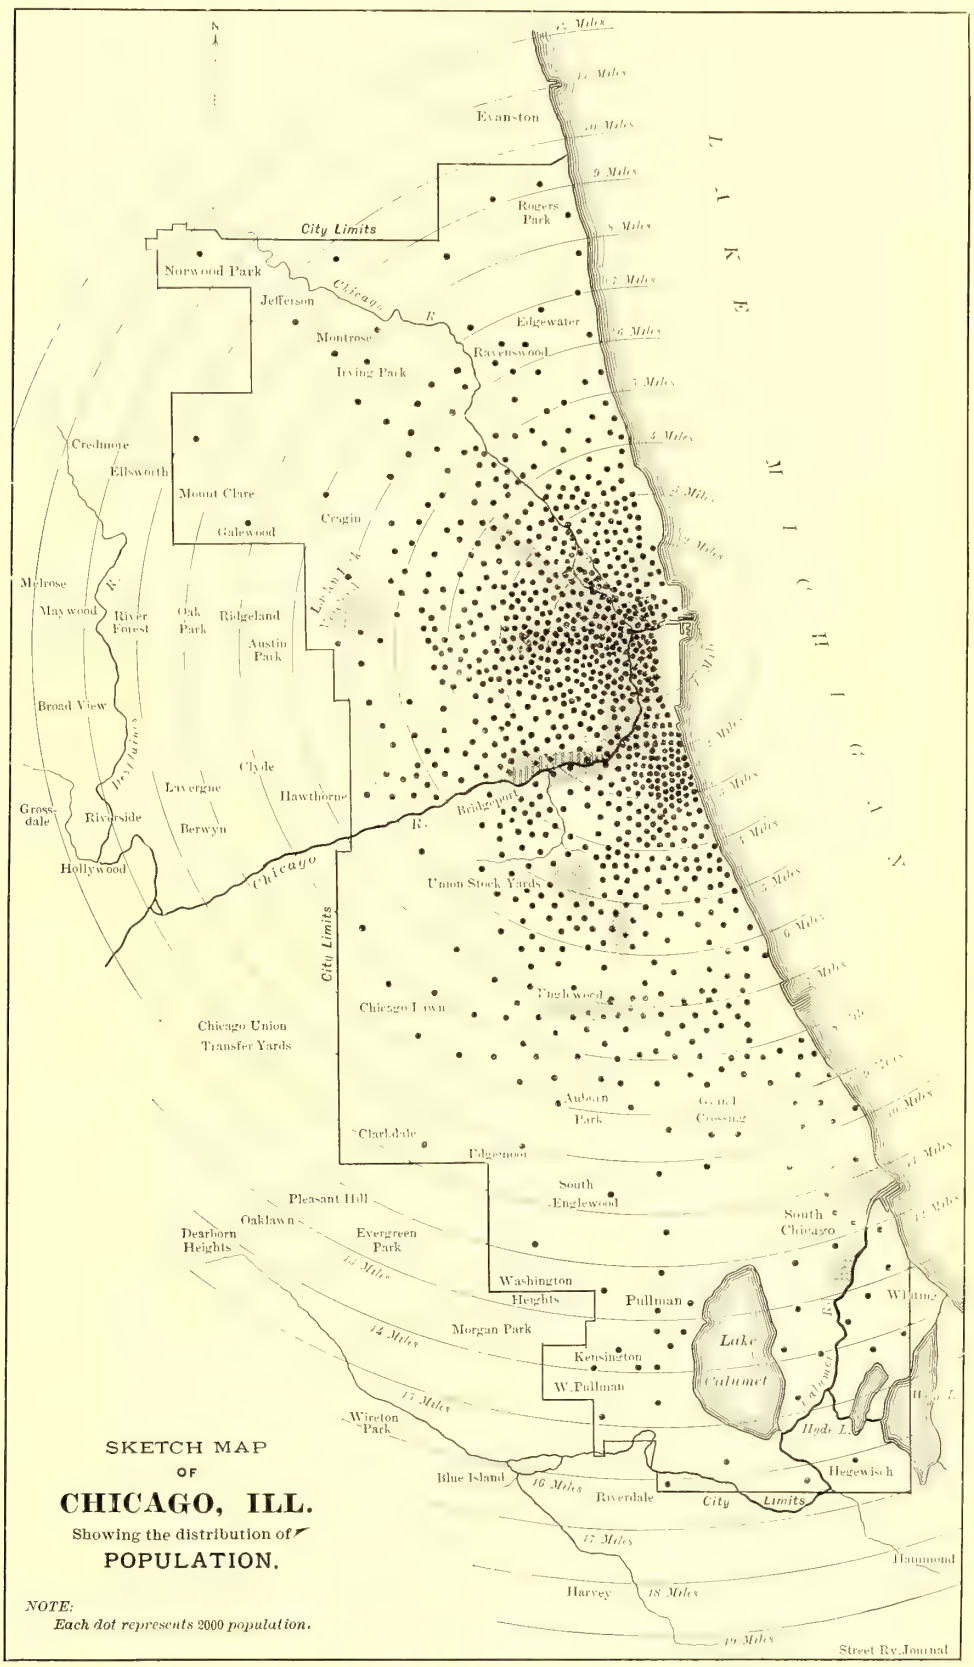
railways, while worked out quite carefully experimentally, has not yet been adopted by any important American system on a scale sufficient to justify an opinion as to its permanent value.



ROADBED CONSTRUCTION

Concrete substructure for track is as yet little used in America, partly because of its cost and partly because it is by many considered as making the track too rigid, non-yielding and disagreeable to passengers on the cars which ride over it. The common practice is to dig a trench in the ground, place ordinary or creosoted ties therein on a layer of broken stone or gravel of varying thickness, at distances of from 24 ins. to 36 ins. between centers (24 ins. and 30 ins. being frequent specifications), spike to these ties 7-in. or 9-in. girder rails, according to the height of paving blocks specified by the city, and, finally, tamp the ties carefully to surface. Between the ties is placed broken stone and above that a layer of sand to form a support for the paving stones. Tie rods are sometimes, though not generally, used in a construction of this kind. The practice of using concrete beams or "stringers" underneath the ties for additional strength of support has come into vogue latterly with a number of city systems, but the results of this practice are not yet fully demonstrated.

Rail is almost universally ordered now in 60-ft. lengths, and practically all the mills have provided manufacturing and shipping facilities for these lengths, finding that customers will no longer order 30-ft. rail. By this means, the number of joints, always the weak point in a track construction, have been cut in two for any given length of track, and no greater effects of contraction and expansion, certainly in rail imbedded in paving.

Joints are placed sometimes "opposite," sometimes "broken," and there is not yet any well settled practice on this point, although the tendency is toward the "opposite" form. The natural advantage of broken joints is held to be neutralized by a peculiar and highly disagreeable rolling motion of the car when the joints are seriously down, while with opposite joints the motion of the car is far less unpleasant, although perhaps slightly more noisy when joints are very poor.

The process of "cast welding" has come into very large use during the past four years and with generally satisfactory results. When the joints are well made, the percentage of breakage is comparatively small, and the opinion among street railway managers seems well settled that an exceedingly smooth and perfect riding track can be obtained and maintained by this means. Experiments in electric welding have been carried on for two or three years with varying success, the latest work, such as that in Buffalo, appearing to be quite promising, though the cost

is still rather high. There are a number of excellent special patented joints, some of which are strong and durable and can hardly fail to keep rail ends in position or to bring up old track to surface. The ordinary fish-plates, from 30 ins. to 36 ins. in length, are also used in many cases and give much better results than were obtained from the shorter fish-plates formerly common.

A number of large rolling mill and other manufacturing companies have gone extensively into the business of making "special work," switches, curves, crossings, etc., for street railways, and are producing some excellent material. In a few cases, the street railway companies themselves make their own special work, but in the majority of instances it is purchased on drawings and specifications. The wearing parts, such as switch points, frogs, etc., are generally reinforced by pieces of extremely hard steel made in various secret compositions let into the frog or switch point, and renewable when worn out.

Rail bonding for the return circuit is usually done with copper where the rail joint itself is not relied upon for the conduction of current, as is sometimes the case with cast or electric welded joints. The ends of such bonds are usually expanded into holes drilled in the web of the rail. Care is always taken to so proportion the bond as to give it a conductivity a little greater than that of the rail itself. The rails are frequently double bonded, often by one bond passing around the outside of the fish-plates, while the other is a short one placed within the space between fish-plate and rail. The rails of a track are usually cross bonded at short intervals. The "plastic," or amalgam bond has come into quite wide use also, and is so proportioned as to lie underneath the fish-plates. Curiously enough, there has been some trouble with the stealing of copper wire bonds outside the fish-plates, and for this and other obvious reasons, the shorter bond held by the fish-plates, has some advantage over the longer.

ROLLING STOCK

The general drift of practice is toward long, double truck cars, 30 ft. to 35 ft. over all, for suburban and interurban service, and even in some cases for city lines, although rather in the larger than in the smaller cities, inasmuch as the traffic is more continuous throughout the day, and the proportion of the time when the cars run lightly loaded is small. Trail cars are now rarely used, as it is considered that they cost more for labor per passenger carried, to largely increase the accident account, and, frequently, to involve difficult switching problems at termini. While the long cars are, of course, much heavier than the short ones formerly used, the hammer blow on track joints must be much less because the weight is divided among eight wheels instead of four, while there is none of the oscillation which comes when a long car is mounted on a single truck.

The "maximum traction" type of truck, where from 60 per cent to 70 per cent of the car and motor weight is distributed on four of the eight wheels of a long double truck car, is coming into quite general use, particularly in cities where the grades are severe or where rapid acceleration is required. There have been great improvements in the building of trucks for electric cars during the last three or four years, and all the leading types are now mechanically very well designed and durable.

The standard winter car in most of our cities has broad platforms, large windows and longitudinal seats, while the usual summer car has cross seats and running foot boards on both sides. There is little question that the public prefers cross seat cars as a rule, but for many reasons they are not so desirable from a street railway standpoint as are the longitudinal seated cars.

The one great disadvantage of a double equipment for summer and winter use lies, of course, in the difficulty of properly pleasing the public in spring and fall or in rainy weather in summer. It has been necessary either to have a full motor equipment for both closed and open cars, or to have a quick means of shifting closed and open bodies on to common motor trucks, while nothing has ever been found to provide properly for rainy weather conditions. There have latterly been devised, however, several types of "duplex" or "combination" cars with sides which will roll or fold up into the roofs in such a way as to make the car almost instantly convertible from closed to open, or vice versa. These cars are expensive to build and to purchase, but as they are intended to take the place of a summer and winter car and to furnish advantages which both together do not possess, it would be decidedly profitable to pay a high price for them, provided that there are no mechanical drawbacks. So far, they have not been in use long enough to demonstrate their durability or cost of maintenance, but they are among the most interesting of the present "experiments" now being tried in America.

The American electric motor is so well known throughout the world that there is little need of describing it at length. It is sufficient to say that its main qualities are (*a*) a high efficiency throughout a wide range of action, (*b*) load and speed curves adapted for the particular work to be done, no manufacturers consenting to furnish motors without full knowledge of all the local conditions, (*c*) their multipolar construction with separate coil armatures and high insulation throughout, (*d*) flexible support at one or both ends, (*e*) ease of inspection, and (*f*) a series multiple control through non-sparking contacts protected by magnectic blow-out device.

Powerful electric snow plows, capable of throwing snow in continuous streams away from the track, form a necessity of street railroading in the North, which has been well met by the manufacturers.

With the introduction of the long cars and of trains of cars in a city street has come the necessity for better braking power than has ever before been given to the old horse or cable railways, and many different forms of electric, compressed air and mechanical brakes have been devised to meet different conditions. Until recently, however, street railway managers have not been willing to spend large sums of money for special brake equipment, partly because of the cost, but chiefly because the brake manufacturers themselves have not been able to fully guarantee the life or working efficiency of their devices. Now, however, their apparatus has been brought up to such a point of excellence that they can readily do this, and there is little question that within a short time mechanical braking in some form where quickness of application is possible, will be adopted by many, as it now is by a few of our leading street railway companies.

POWER STATIONS

The horizontal or vertical, tandem or cross compound engine in large sizes, direct connected to multipolar electric generators, form the prevailing type of power station "unit" in use in America, small high speed engines with

belt connection for generators having long since passed into the background. Water tube boilers are generally used, but not a few managers still place their trust in the "old, reliable, horizontal, return tubular, boiler" of their forefathers. Such a boiler is no doubt economical, but it does not respond readily to the wide fluctuations in the demand for steam coming from electric railway engines, where loads vary so widely, and unless a large boiler surplus is provided, there are sometimes more or less serious difficulties in keeping a road running.

It goes without saying that in the best modern plant, careful provision is made for the economical storing and handling of coal from the point of delivery to the mouth of the furnace, and hand labor is reduced to a minimum.

The piping system was originally "duplicate," and even now this practice is quite common, but there are also many engineers who prefer to "place all their eggs in one basket and watch that basket," by putting in a single, well designed direct system with carefully made valves and appurtenances.

Where water for condensing purposes is not obtained, water cooling towers have come into use with very good results, and this plan is particularly applicable, of course, to central city stations. Every effort is made in our best stations to save the energy of the steam by feed water heaters, fuel economizers, and other economic devices.

Nearly all the engines now in general use in street railways are using some modification of the Corliss valve rigging, although there are several well known and popular engines which are working on different principles and with success. The electric generators are, as before stated, multipolar and are far better built now than ever before, special care being taken in all insulating processes. The largest engine generator so far built in this country has an economical rated capacity of 4500 h.p. and a maximum of 7000 h.p., and a great many of this size of engine have been ordered for the larger stations.

Broadly speaking, it has been proved possible to generate power for railway purposes in the best American stations at from $.005 to $.0075 per kilowatt hour, but in by far the larger number of stations it is still costing $.01 or more; these figures all covering cost for labor, fuel, water, material and repairs of power plant, and excluding interest on investment and allowance for unrealized depreciation.

DISTRIBUTION SYSTEM

The very latest practice in electric power distribution for large city railway plants—a practice represented more, however, by plans drawn and orders placed than by actual accomplishment—is the generation in a central power station of three-phase, high tension current, its transmission to a number of sub-stations at the high initial tension and its distribution through rotary converters and constant potential circuits into 500-volt direct current, adapted for the railway motors in common use. It is only by this means that the investment for copper and for conduits can be kept within reasonable limits on a large city plant, and although no comparative estimates of cost and running expenses have yet been given out, there is little doubt that this practice will become quite general for larger plants.

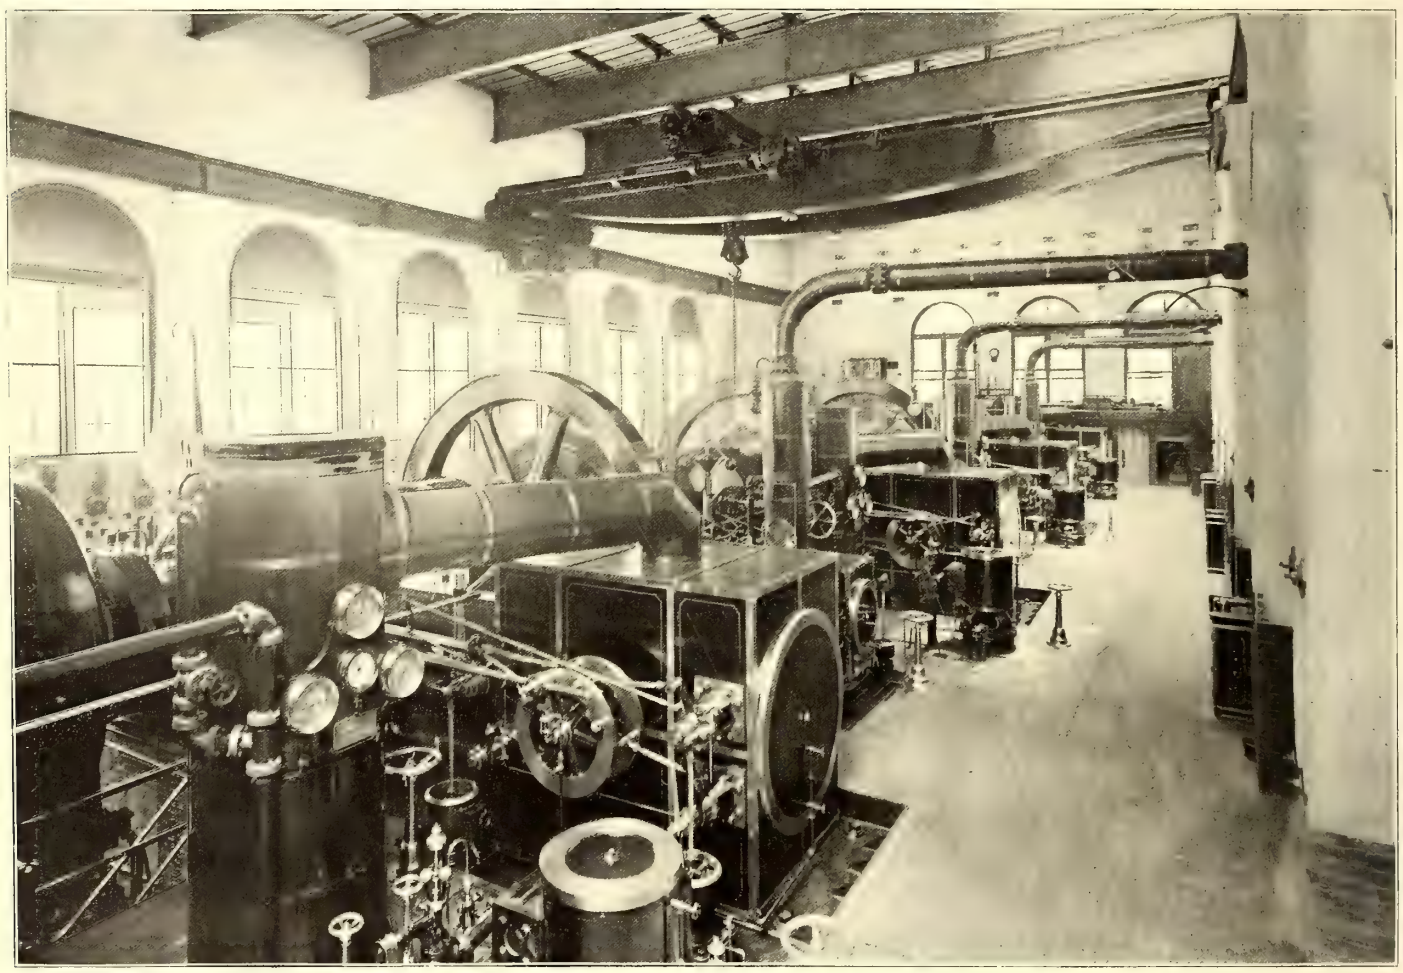
In practically all new work in the larger cities the feed wires are being carried underground in vitrified brick or clay, or iron pipe conduits. The feeders are stranded copper cables carefully insulated and lead covered. Alumnium is being tried for feeders, but it is too early to be sure of results.

Poles are now almost universally of iron except in the smaller cities, and on the suburban or interurban lines, where they are of wood, usually in the natural state, untreated by preservative compounds. Little desire is shown by American municipalities to have the railway companies use elaborate or highly ornamented poles, the general feeling being that so long as graceful lines are preserved, the simpler the pole the less noticeable is it in the street. The whole idea has been not to call attention to the poles even by beauty and elegance of design, but to minimize their obtrusiveness.

The devices for holding the trolley wire in position over the track and for making curves, turnouts, etc., have been developed to a point where the best types can be considered as highly satisfactory and as well serving their purpose. There is very little trouble now from break-downs of trolley wire, the overhead structure being built permanently and well.

Without further description of the latest standard American practice, we will take up the Chicago street railway system in its entirety, discussing as briefly as may be the decisions which have been made and the reasons therefor, by which the present stage of development—not yet a final one by any means—has been brought about.

THE TRANSPORTATION SYSTEM OF CHICAGO

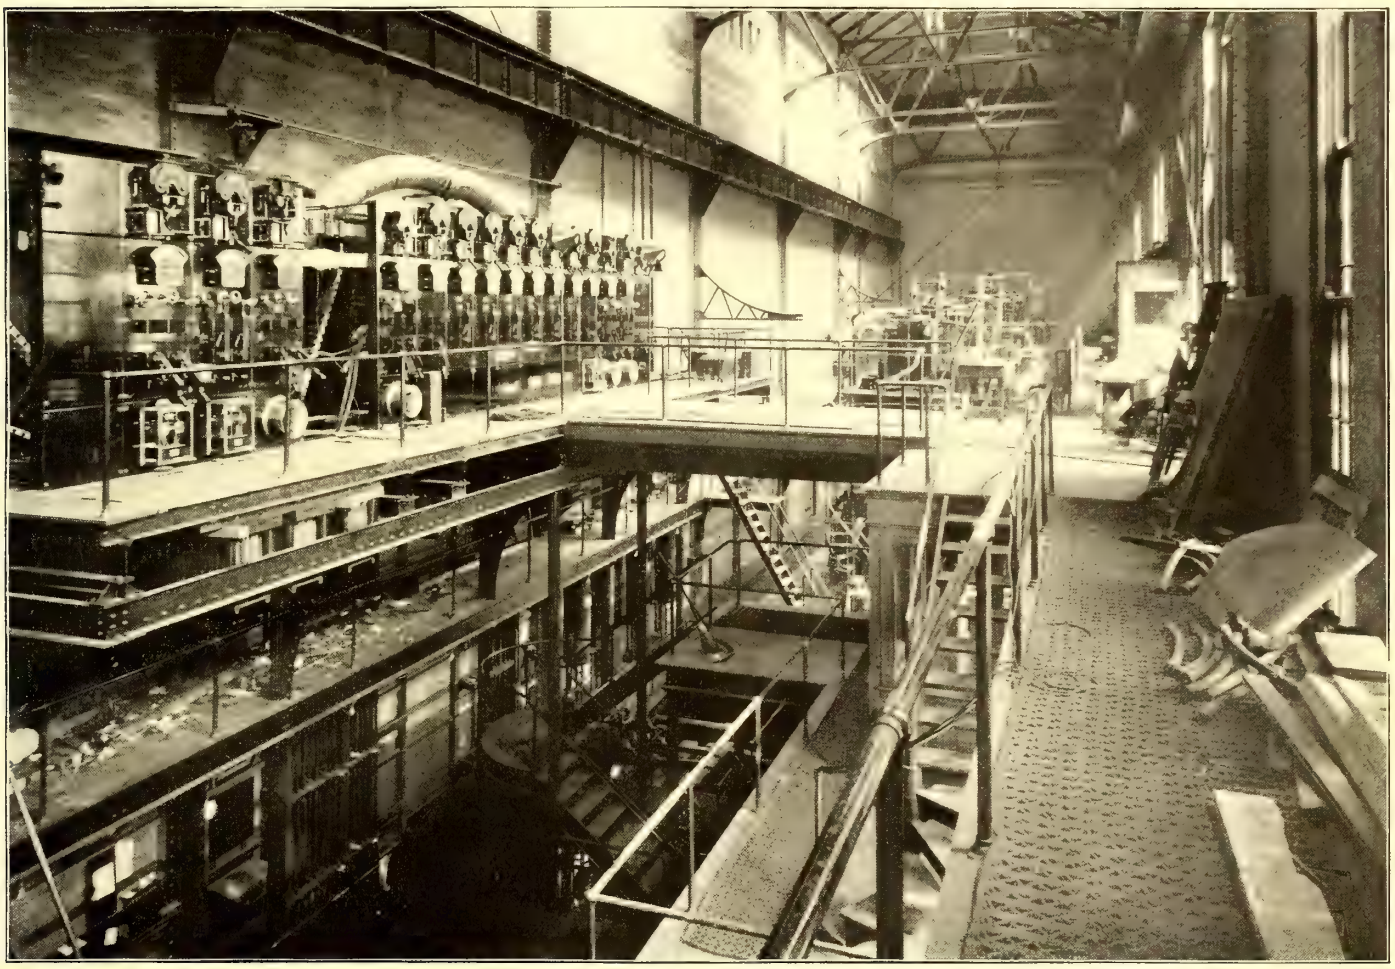


The Chicago River has played a part in the world wholly out of proportion to its size or intrinsic importance. Rising nowhere, it empties into an inland lake. At its broadest point it is little more than a creek and its navigable length is hardly a mile. Yet the existence of this little river with the possibilities which it offered of harborage, dockage and warehousing, led to the selection of its neighborhood, from the surrounding prairies and shorelands of the lake district, as the site for a little settlement. In course of time railroads came to town, the lake traffic grew to large proportions and the advantages of this site for transshipment of Western produce from railroad to water and vice versa were found to be so great that more, and still more railroads sought lake connections here until first gradually, then rapidly, then by immense forward leaps and bounds has been built up the great metropolis of the West, a city even now ranging among the half dozen great commercial centers of the world.

The Chicago River has dictated the geography of the city, dividing it into the North Side, South Side and West Side (see page 615), and has ruled in effect that the financial, business and shopping center of this great city shall be confined within the limits of the narrow peninsula bounded on two sides by the river and on a third by the lake. Into this little district each morning pours an enormous swarm of busy workers, getting over and under the Chicago River as best they may, or waiting patiently for boats to pass and bridges to be lowered. They crowd the immense "sky scrapers" which first attained their highest development in Chicago as a necessity of the situation, and which during the working hours of the day probably give to this business district the largest number of living souls per square inch of ground area to be found in any city of the world. The congestion in the streets of Chicago's

business district, morning and night, is something appalling, and a faint conception of it only can be given by the accompanying illustrations. Thousands of surface car trains of three, four and even five cars pass into and out of this district around loops or through switchbacks, the separate ownership until now of the North, West and South Side lines having made through runs impossible. Hundreds of elevated trains reach the Union Loop terminus and pour their thousands of additional passengers upon the streets. All is noise, bustle, apparent confusion and extreme congestion to sidewalks in this busy, throbbing heart of Chicago.

This congested business district dominates the entire transportation system of Chicago, determines the time interval between cars on all lines and has led to the universal running of surface cars in trains as against the unit system prevailing in most other American cities. The reason for this may be explained in a word. On each side of the city, north, west and south, there are several through or main lines radiating from the business district and intersected at many different points by cross, or feeder lines. Until the past three or four years nearly all the radiating lines have been run by the cable system, and the feeder lines by horses. The latter could not, of course, be allowed upon the radiating lines since they would greatly interfere with the speed of the cable cars, consequently, the horse cars have been brought to the intersecting points and have there been coupled to the cable cars, which in the course of their runs thus collect several horse cars at different intersecting points. On the return trip, the horse cars were disconnected, horses attached and the passengers carried to any point on the feeder lines without change of cars.



Within the past five years these horse feeder lines have been converted to electric traction, and it has been the constant effort of the Chicago street railway companies to secure from the City Council the right to run the electric cars down over the radiating lines between cable cars, for it imposes far too great a strain upon the cable to attach several heavy electric cars to the grips, and it is equally undesirable to give the passengers the trouble of transferring at intersecting points. This effort to secure electric rights into the center of the city has been successful in several instances, and undoubtedly will be so universally in the near future, for it has been proven again and again that the people greatly prefer electric to cable cars, and the latter will be abandoned for the former even at some inconvenience and additional walk.

ENGINE ROOM, SOUTH SIDE ELEVATED RAILWAY

When the entire Chicago system is operating by electricity, the probabilities are that the system of running cars in trains now in vogue will be largely done away with, and long double truck cars will come into general use instead, although the multiple unit system of car control would render it possible to run surface cars in trains to considerable advantage on some of the most heavily patronized lines. It is also more than probable that with the general consolidation of Chicago street railway properties which has now begun, and which can hardly fail to be completed within the next two or three years, the use of loops and switchbacks in the business center of the city will largely cease and cars will be run right through from North

to South and West Sides without change, and with immeasurably less traffic difficulties to overcome. On such a plan the combined city system can run a far greater number of cars than at present, and can also give universal transfers, thus making it possible for passengers to go any where they will throughout the city on the payment of a single fare. Such a plan, however, cannot be carried out unless the entire system be operated by one motive power and the cable done away with, for to obtain the greatest flexibility and ease of handling, uniformity of equipment is an essential, in order to avoid traffic difficulties at congested points.

GALLERIES IN POWER STATION, METROPOLITAN WEST SIDE ELEVATED RAILWAY

By reference to the accompanying map of Chicago, it will be seen that there are three large central transportation systems in Chicago owned by the Chicago Union Traction Company, the Chicago City Railway Company and the five elevated railway companies together, while there are also eight smaller properties, which are all, in reality, feeders to the three large systems just named, or to each other. The Chicago Union Traction Company is a consolidation, recently effected, of the North Chicago Street Railroad Company and the West Chicago Street Railroad Company, the former operating the lines north of the Chicago River and the latter those to the west, and both reaching the congested district near the lake front.

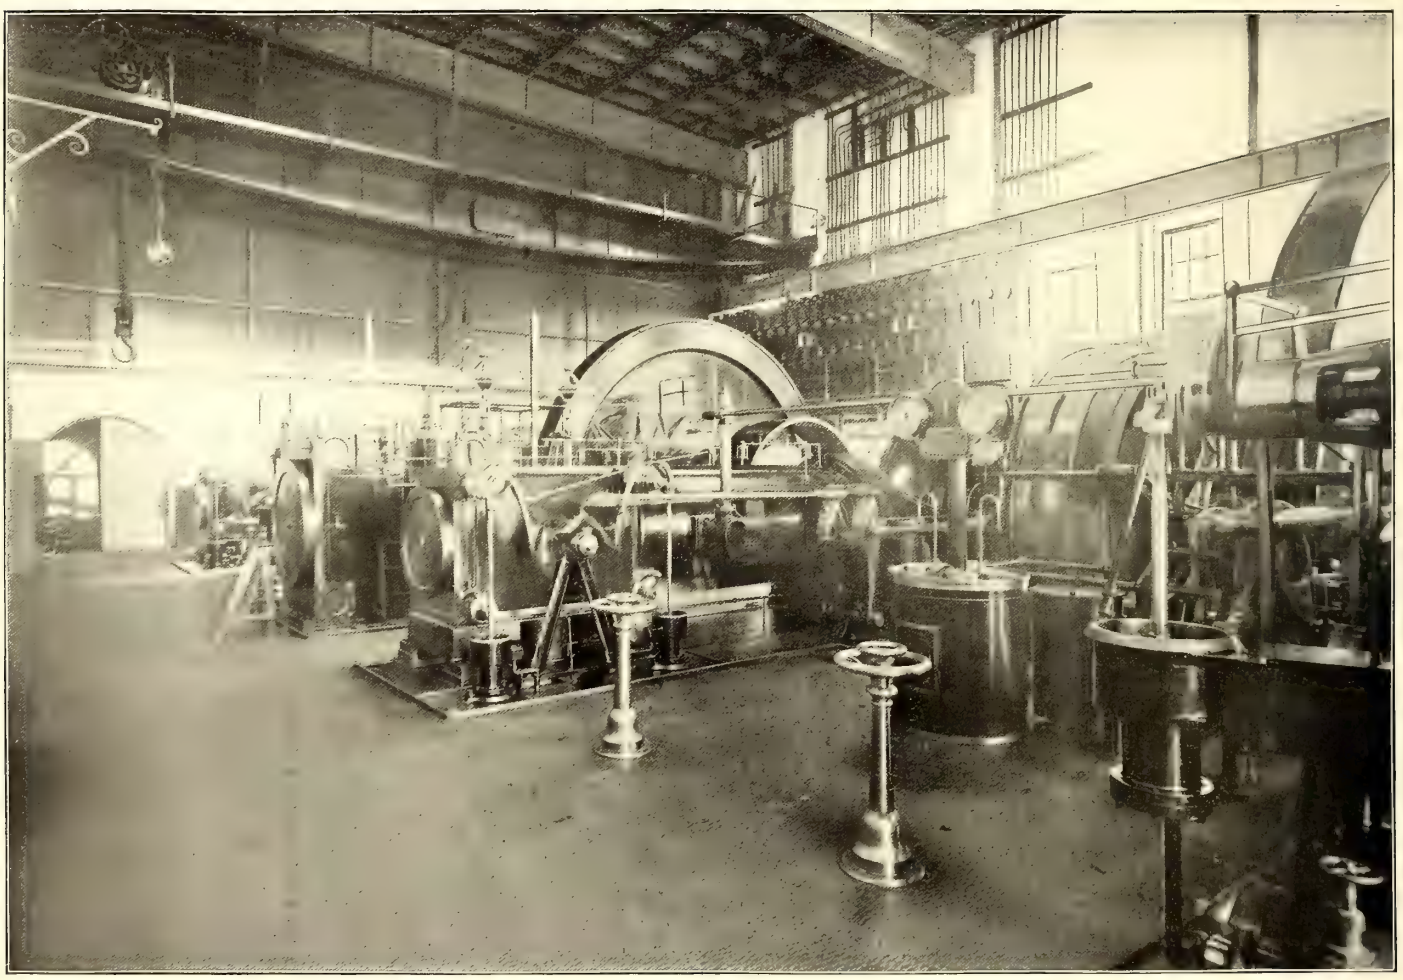
Seven of the outlying feeder systems formerly more or less independent of the North and West Side systems have recently been consolidated into the Chicago Consolidated Traction Company, which owns two city lines reaching the congested district over the tracks of the Chicago Union Traction Company. To the south of the Chicago City Railway system is a quite extensive network owned by three independent companies, the Calumet Electric Street Railway Company owning one of the largest purely suburban systems in the world, the South Chicago City Railway Company, and the Chicago Electric Traction Company (formerly the Englewood & Chicago Electric Street Railway Company.)

The track mileage owned by the eleven principal Chicago companies, the gross receipts of many of them, and the gross receipts per mile of track are shown in the following table:

SURFACE RAILWAYS	Miles Track	Gross Receipts	Receipts Per Mile Track
Chicago Union Traction Co.	304	$7,047,227	$23,182
Chicago City Railway Co.	197	4,832,806	24,532
Chicago Cons. Traction Co.	206	1,026,781	4,984
Calumet Electric Street Ry. Co.	90	....	....
Suburban Railroad Co.	56	....	....
So. Chicago City Railway Co.	37	....	....
Chicago Electric Traction Co.	35	....	....
Chicago General Railway Co.	30	119,739	3,991
ELEVATED RAILWAYS			
Metropolitan W. S. El. Ry. Co.	36	1,246,833	34,634
South Side El. Ry. Co.	19	978,330	52,598
Lake Street El. Ry. Co.	15	633,404	42,227

From this it appears that the greatest traffic density of all lines is found on the South Side Elevated Railway, while that of the Chicago General Railway and the Chicago Consolidated Traction Company are far less than all of the others whose returns appear.

In this connection it may be interesting to note that the



gross receipts per mile of track of the North Chicago Street Railroad Company, one of the components of the Chicago Union Traction Company, were in 1898, $29,855, while those of the other component, the West Chicago Street Railroad Company, were $19,862. The section of the city north of the Chicago River is narrow and wedge shaped, and the large number of people living in this territory are forced upon comparatively few lines, so that the reason for the greater traffic density of the North Side system as compared with the West Chicago system, which reaches a much larger area, is obvious.

United as the Union Consolidated Traction system, the North and West Side lines form an immensely valuable property, which can be operated far more economically together than under separate management, particularly on account of the possibility of running cars through from North to West Sides and return, without the delays incident to switchbacks or loops, by means of which a much greater number of cars can be forced through the congested district, as explained above.

The Chicago Consolidated Traction Company was organized early in 1899 as a consolidation of the following properties:

	Gross Receipts	Earnings from Operation
Chicago Electric Transit Company.....	$278,574	$116,297
Chicago & Jefferson Urban Transit Co.....	44,821	12,470
Cicero & Proviso Street Railway Company.	226,722	72,853
Evanston Street Railway Company.....	17,097	4,474
North Chicago Electric Street Railway Co.. (Including the Chicago North Shore Street Railway Company, operated under lease.)	330,266	161,986
North Side Electric Street Railway Co.....	67,428	31,011
Ogden Street Railway Company.....	61,870	7,198
Totals	$1,026,788	$406,292

All of these properties are located on the North and West Sides, and are feeders to the two great properties in those sections, most of them in outlying territory. The Chicago & Jefferson Urban Transit Company and the Chicago Electric Transit Company, however, own lines reaching quite well toward the business district, though dependent upon the Chicago Union Traction Company for entrance into the congested district.

LAKE STREET POWER STATION, CHICAGO CONSOLIDATED TRACTION COMPANY

The Chicago City Railway Company has always had a monopoly of the through traffic between the great South Side district and the heart of the city, except for the competition of the South Side Elevated Railway Company, which has been partially nullified once or twice by the purchase of control by Chicago City interests. The Chicago City Railway Company was the first company east of San Francisco to adopt the cable system for the operation of several of its through lines, and its financial success has been phenomenal. It is to-day one of the most strongly entrenched and valuable properties in the country.

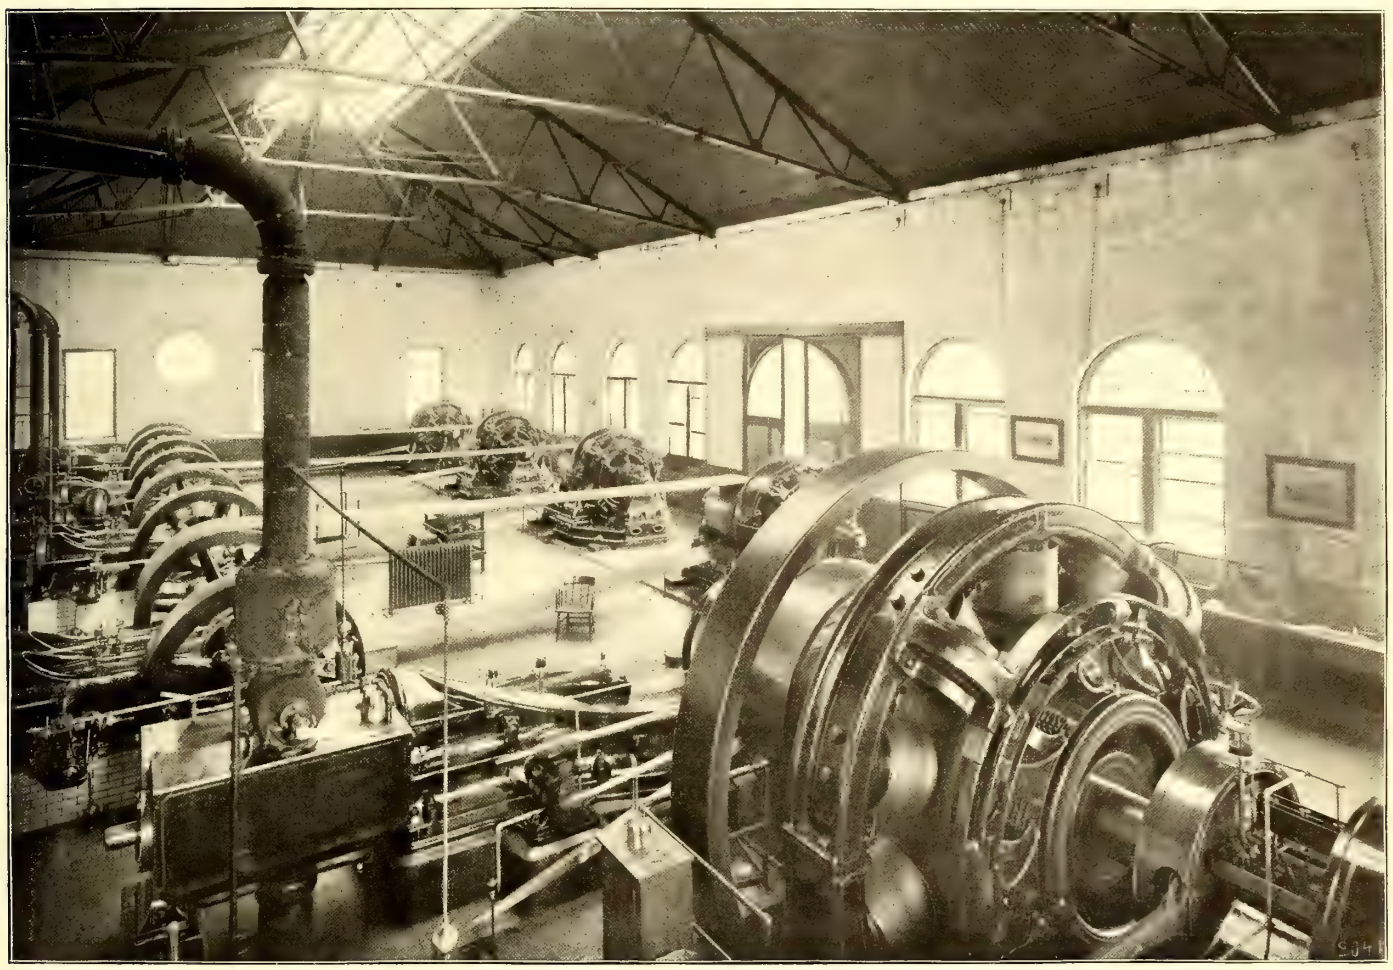
The Calumet, South Chicago City and other properties in the extreme southern portions of the city are working in comparatively new territory, which will undoubtedly be the seat of a large population in the near future. Unfortunately, for several years past, this district has been suffering from a reaction from the World's Fair "boom," which abnormally increased real estate values and speculation in and around Jackson Park, but there are indications that

the tide has again turned upward, and that there will be a healthy growth in population henceforward.

As throwing light on the reasons why the cable system is disappearing even from Chicago, where its hold has been strongest, it will be interesting to quote the comparative costs of operation of horse, cable and electric traction on the lines of the Chicago City Railway Company. This company operated its electric cars in 1898 at 12.9 cents per car mile, its cable cars (including trailers) at 10.8 cents and its horse cars at 27.2 cents; while the electric cars earned 22.7 cents per car mile, the cable cars 16.5 cents, and the horse cars 16.6 cents. The net earnings per car mile of the electric lines were therefore 9.8 cents, while the cable lines earned only 5.7 cents, and the horse lines actually showed a deficit from operation of 10.7 cents per car mile.

The different Chicago properties which report earnings, exhibit the following percentages of operating expenses to gross receipts for the year ending Dec. 31, 1898.

	Per cent
North Chicago Street Railway Company	*46.1
West Chicago Street Railroad Company	*50.0
Chicago City Railway Company	†60.6
Chicago Consolidated Traction Company	*60.4
Chicago General Railway Company	*49.8
South Side Elevated Railroad Company	‡53.5
Lake Street Elevated Railroad Company	‡51.2
Metropolitan West Side Elevated Railway Company	‡47.4



*Operating expenses exclude taxes.
†Operating expenses include taxes.
‡Operating expenses exclude taxes and loop rental.

THE POWER STATIONS OF CHICAGO

The general design and relative sizes of the power stations of Chicago may be understood from an examination of the diagrams on the inset between pages 628 and 629, and a good idea of the character of the work done in them appears in the accompanying illustrations. It will be seen that there is a wide variety of practice in the city stations, and that several of them are not of the most modern types, but would be built quite differently were the work to be done to-day instead of four or five years ago, in the light of later experience.

Several of the stations, however, are admirable. That of the South Side Railway Company, designed by Sargent & Lundy, is one of the most economical railway power stations in the world, if not, indeed, the most so, its cost of operation being well below 7½ mills per kw. hour. The original equipment of this station was with four horizontal, cross compound Allis engines, with cylinders 26 ins. and 54 ins. x 48 ins., each driving an 800-kw. Westinghouse generator, and there are now building two additional cross compound Allis engines, with cylinders 34 ins. and 70 ins. x 54 ins. to drive 1600-kw. Westinghouse generators. The new engines are capable of working up to a maximum of 4000 h.p., and their speed is 80 r.p.m. with 160 lbs. steam pressure.

Twelve B. & W. water tube boilers are installed in the station, with 48,000 sq. ft. of heating surface, and these are fired by means of B. & W. automatic chain grate stokers, fed by pendulum chutes communicating with steel

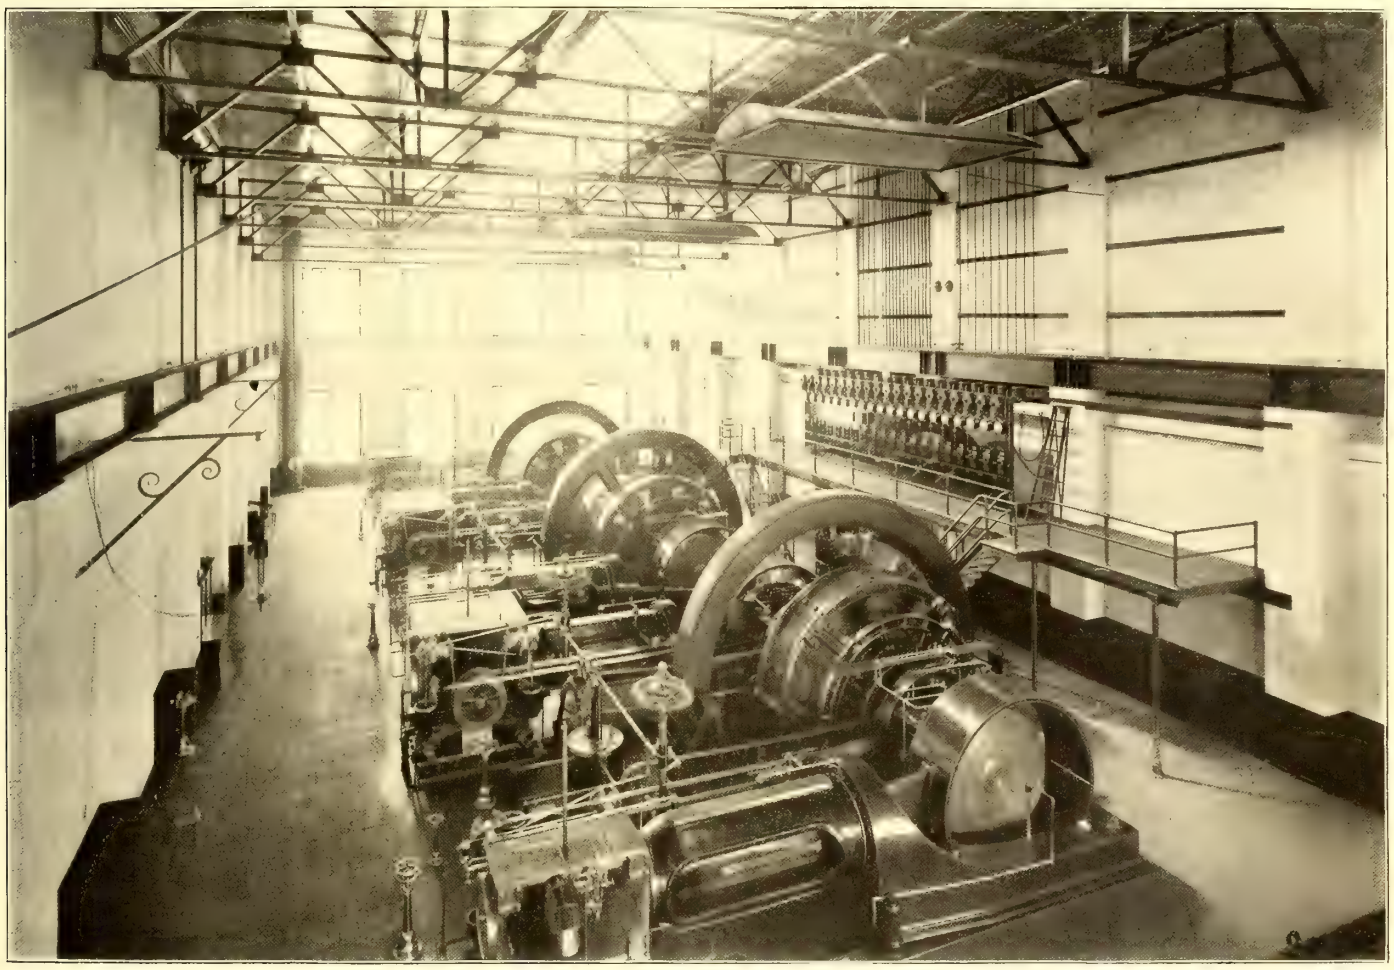
POWER STATION, CALUMET ELECTRIC STREET RAILWAY COMPANY

storage bunkers supported above the boiler room, to which coal is delivered by the Mead Company's McCaslin coal conveyors. Reynolds condensers and Blake pumps are used, together with the Warren-Webster feed water heater and the Green fuel economizer, the latter consisting of 832 tubes. The course of the feed water is through the heater, thence to the pumps, the economizer and to the boilers.

One of the most interesting features of this station is the water cooling tower, located outside of the power station proper. This was installed by the Wheeler Condenser & Engineering Company. The tower is 64 ft. long, 34 ft. high and 16½ ft. wide. It is to be enlarged to correspond with the increase in equipment now being made, and is to be extended in height so as to bring the shell above the roofs of the adjoining buildings, this being found necessary on account of local annoyance from the spray from the towers.

The condensing water is pumped to the top of this structure, where it is thrown upon vertical wire screens, down which it trickles, and by means of which it is brought in contact with an air blast created by a system of fans. These fans are ten in number, each 10 ft. in diameter, and are operated in pairs on the same shaft, but are located one on each side of the tower. In the middle of the tower is a baffling plate, which curves outward in the direction of each fan, and upon this plate the water passes to a tank beneath, so that the air blast cannot blow water from one fan to the other. The five shafts, by means of which the fans are operated, extend across the open space and enter the power station, where each is coupled to an 18-h.p. C. & C. motor, by which they are driven. By means of this cooling tower the temperature of the water is reduced 30 degs. to 40 degs.

The Westinghouse generators were built upon specifications which provided that they should be operated continuously at a load of 650 volts and 1230 amps., and to operate at 650 volts and 1845 amps. for three hours without injury. The minimum insulation resistance between copper and iron was required to be 2 megohms and the field coils were required to be capable of withstanding an alternating current of 3500 volts. The machines are guaranteed to have an efficiency of 94½ per cent at full load. In practice the machines work from no load to 50 per cent overload without sparking at the brushes, which rarely or never need to be adjusted after being once set.



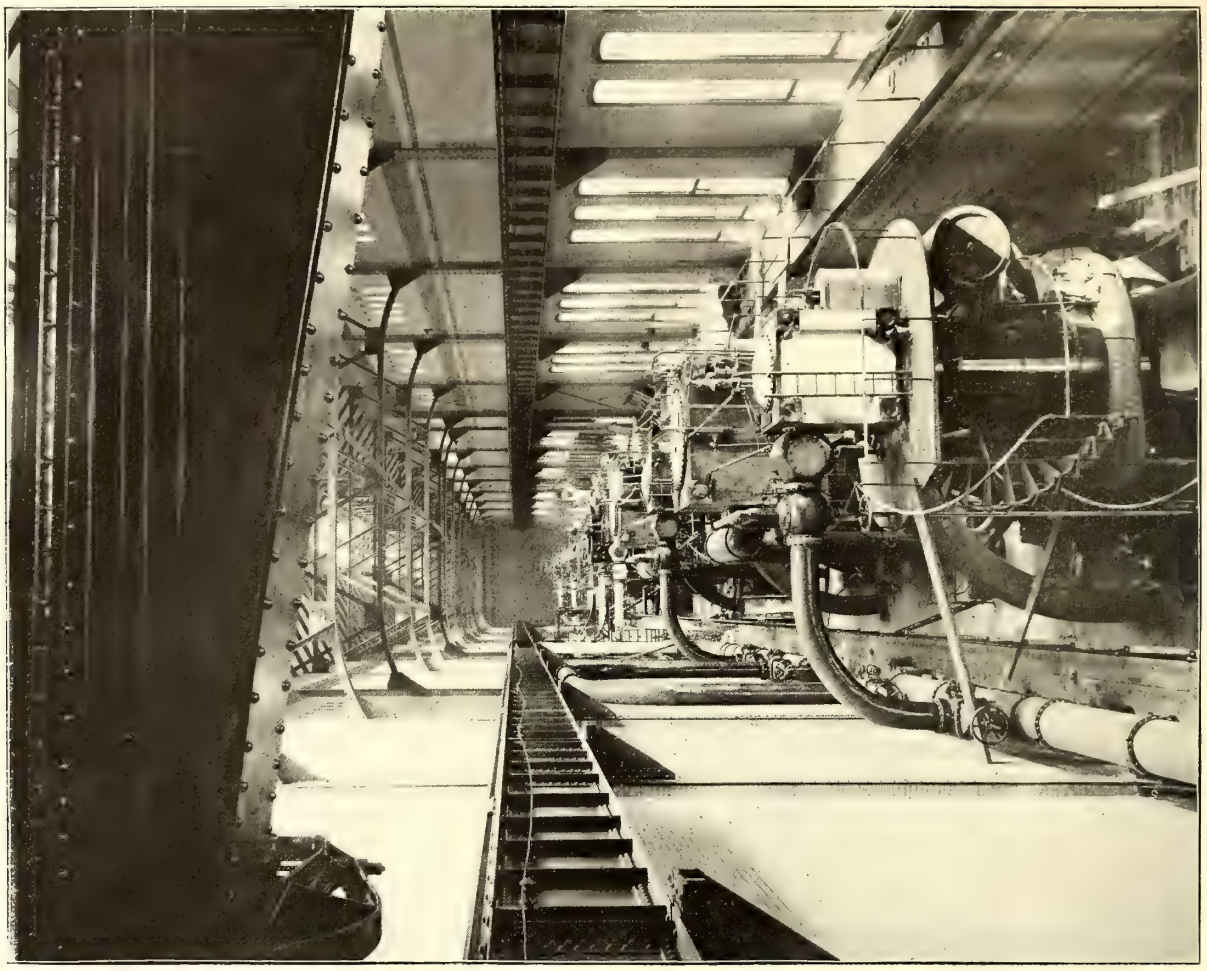
CALIFORNIA AVENUE POWER STATION, CHICAGO UNION TRACTION COMPANY

Included in the auxiliary equipment of the engine room is a Turner automatic oiling and filtering device, manufactured by the Economic Machine Works, of Chicago, and a 30-ton electric traveling crane, made by the Morgan Engineering Company, of Alliance. This crane has a longitudinal speed of 200 ft. per minute and a cross speed of from 50 ft. to 75 ft. per minute.

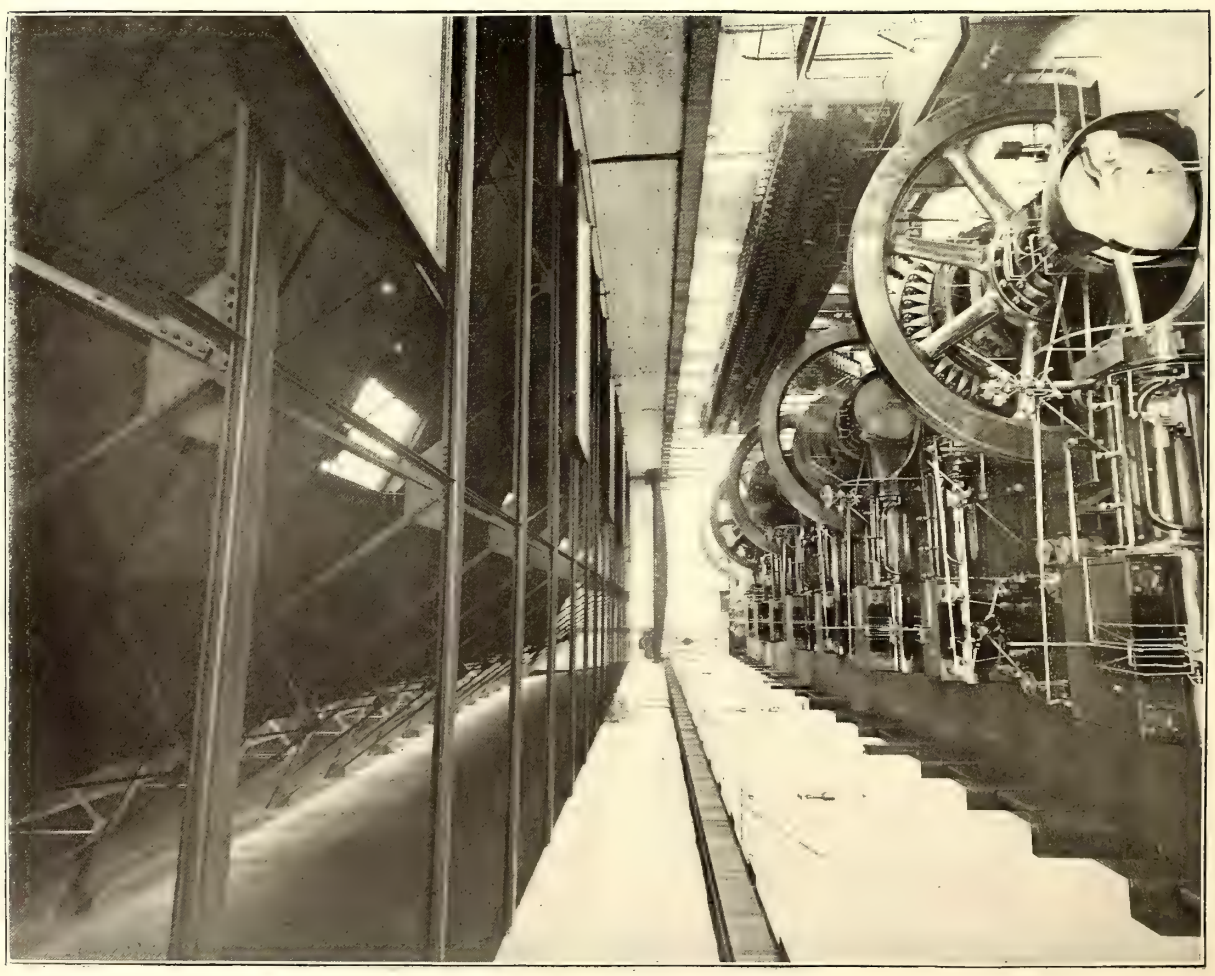
One of the features of this station which has undoubtedly given it its high economy for the fluctuating service for which the station is intended, is the extensive storage battery plant, of which one-half is located at Sixty-first Street, and one-half at Twelfth Street, each being at a distance of about 3 miles from the generating station. Each of these two plants consists of 263 cells of 750 kw.

total capacity, and on fluctuations they can deliver 2400 amps. to the line, while the output has run as high as 4300. The batteries are in charge of the ticket agent at one station and of the train dispatcher at the other, and the only duty of each is to throw in the circuit breakers should they fly out.

When the line was first opened this power station, then consisting of four 800-kw. units, was able to run but ninety cars, of the type shown in Fig. 19, page 635, all of these being motor cars run on the Sprague multiple unit system. Later on, however, when everything became "limbered up" and the motormen became more skillful in handling the cars, the station has been able to run 130 cars regularly, while 167 even have been operated, at a time when it was also necessary to provide for the heating of the cars by the electric current as well as to maintain the regular schedule of sixteen to seventeen miles per hour, including stops. The average power output per car mile ranges approximately from 2 kw. hours per car mile in summer to 3.55 kw. hours in winter, the latter figure including electric heating of cars, and both including lighting, air compressors for brakes, station lighting, switches in yards and power for fan and auxiliary motors.



HOBBIE STREET POWER STATION, CHICAGO UNION TRACTION COMPANY



The South Side and Metropolitan West Side Elevated Railway stations, the Hobbie Street station of the Union Traction Company, the Calumet and South Chicago City stations are the only ones in the city which are operating condensing, though the new Northwestern station will, when completed, be run as a condensing station. The Calumet system of condensation is worthy of description. The original plant consisted of four Ball cross compound non-condensing engines, each belted to two 100-kw. Detroit generators. Under the present management by Mr. Sloan, provision was made to run these engines condensing, and when the change was made each Ball engine was belted to a 150-kw. Walker generator, and the power was thus increased from 250 h.p. to 330 h.p. per engine. At the same time, one 800-h.p. cross compound Buckeye engine was put in, direct coupled to a 500-kw. General Electric multipolar generator. Two Deane condensers were installed, in which a vacuum of 22 ins. to 23 ins. is secured in summer, and 24 ins. to 26 ins. in winter. There being no natural supply of condensing water, it is necessary to use city water and to make provision for economizing it in every possible way. On page 628 is shown a pond located near the power station, and a system of cooling tables. The tables are about 12 ft. wide and 70 ft. long, and the water passes from the delivery pipes to the feeder, when it falls upon the second table and returns to the shore of the pond, from which it is again passed to the condenser. The pond is first filled from city water main, but the supply is reinforced by rain water collected from the roofs of the neighboring buildings and conducted to the pond.

The Calumet power station is shown on page 621, and the very interesting Metropolitan power station and engine room on pages 619 and 624.

The Chicago City power stations are rope driven plants,

ENGINE ROOM, METROPOLITAN WEST SIDE ELEVATED RAILWAY

ENGINE ROOM, WESTERN AVENUE POWER STATION, CHICAGO, UNION TRACTION COMPANY

using small units as compared with present practices. They have return tubular boilers, and Green-Wheelock engines.

The Western Avenue and Hobbie Street stations of the Union Traction Company are shown on pages 623 and 624. The former is the largest surface railway station in Chicago, and contains engines made by Fraser & Chalmers, the George H. Corliss Company and the Pennsylvania Iron Works, all direct connected to Siemens & Halske generators. The last one built, of 500-kw. size, to run in connection with the 2000-h.p. Pennsylvania Iron Works condensing vessel of sufficient capacity to take care of the steam from 1,400 h.p. of engines.

The kilowatt capacity of the principal stations is as follows:

Chicago Union Traction Company—
- Hobbie Street Station.....3,200 kw.
- Western Avenue Station.....8,000 kw.

Chicago City Railway Company—

FORTY-NINTH STREET POWER STATION, CHICAGO CITY RAILWAY

Company's engine, is fitted with an internal commutator different from the Siemens & Halske former practice. Since building this generator further commutator improvements have been made. *

The Green Engineering Company, of Chicago, is now installing twenty of its chain grate stokers to go with the 8000 h.p. of Stirling boilers in this station.

The Union Loop station is interesting, having been originally designed to burn oil as fuel, although on account of a rise in prices this is now understood to have become uneconomical. †

The new Northwestern Elevated station, a description of which appeared in the Street Railway Journal for July, page 452, was designed by J. R. Chapman, and one of its most interesting engineering features is the Weiss counter current central condensing system, in which is a

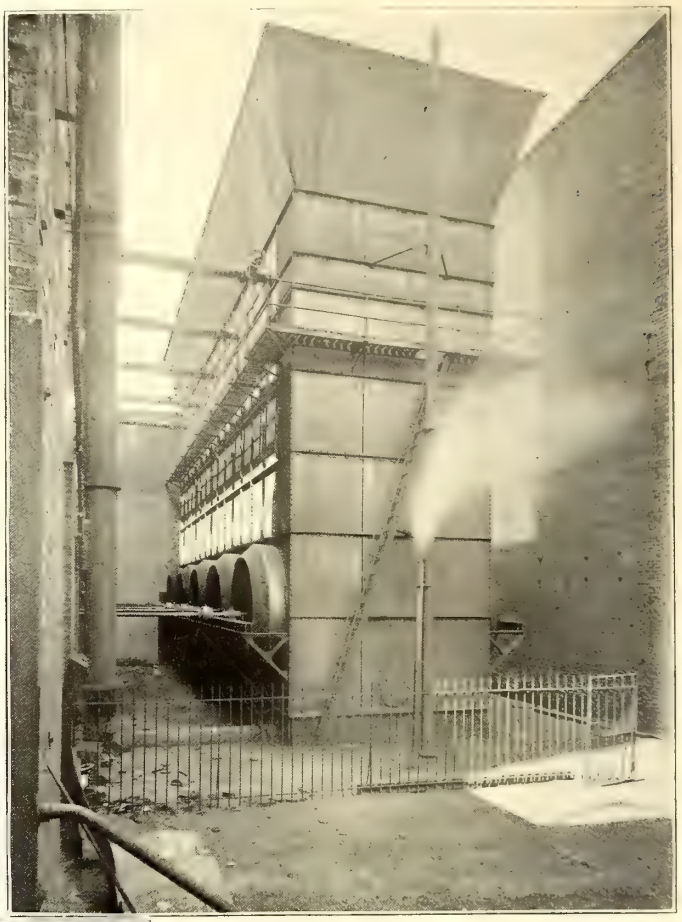
Taking a general survey of the entire power station equipment of the city, it will be interesting to see how the different types of apparatus are represented.

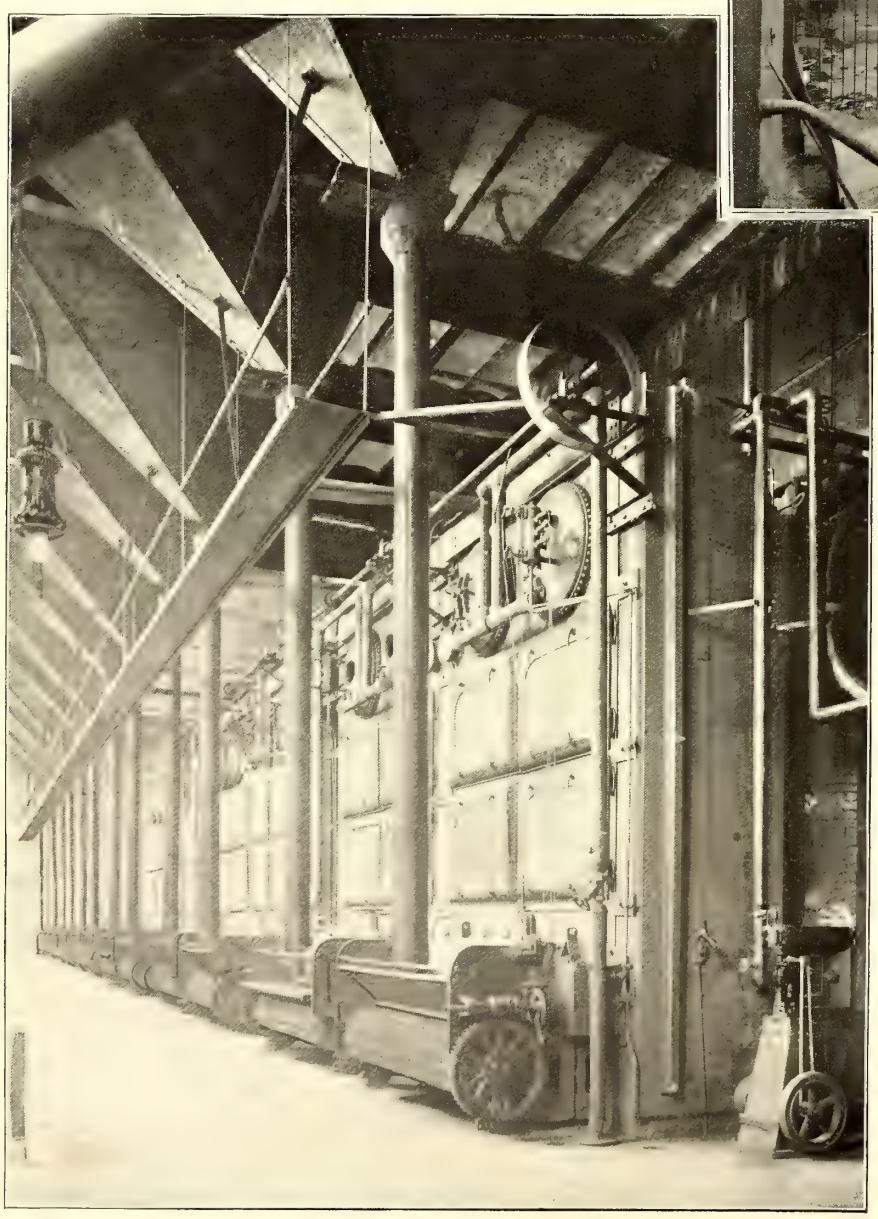
The Babcock & Wilcox Company has installed sixty-four boilers, aggregating 23,600-h.p. capacity in the Metropolitan, South Side, Northwestern and Union Elevated stations; the Stirling Company has placed about 10,000-h.p. of boiler capacity in the Western Avenue plant of the Union Traction Company, and the stations of the Subur-

*For description see Street Railway Journal for July, 1899, page 429.



†For full description of this station see Street Railway Journal for December, 1898, page 769.

ban Railway Company and the South Chicago City Railway Company; 8400-h.p. of Campbell & Zell boilers are used by two of the stations of the Chicago Consolidated Traction Company; and the Abendroth & Root boilers are used by the Chicago General Railway Company; while the Chicago City Railway Company, as before stated, uses return tubular boilers chiefly, together with a Hazelton boiler and a Babcock & Wilcox in one of its stations.



The Green economizers are used in the Metropolitan and South Side Elevated stations, and in those of the South Chicago City, Chicago & Milwaukee and the Chicago Electric Traction Companies.

The Wheeler Condenser & Engineering Company have furnished the South Side Elevated Railroad with a Barnard water cooling plant of 10,000 h.p., previously described, and has furnished the Union Loop station with a 7500-h.p. outfit of "Wheeler Admiralty" surface condensers, Wheeler vertical and horizontal feed water heaters, vertical twin air pumps, centrifugal circulating pumps, etc.

Blake pumps of various types are used in the Union Loop station, the Northwestern and South Side Elevated stations, the Western Avenue and Hobbie Street stations

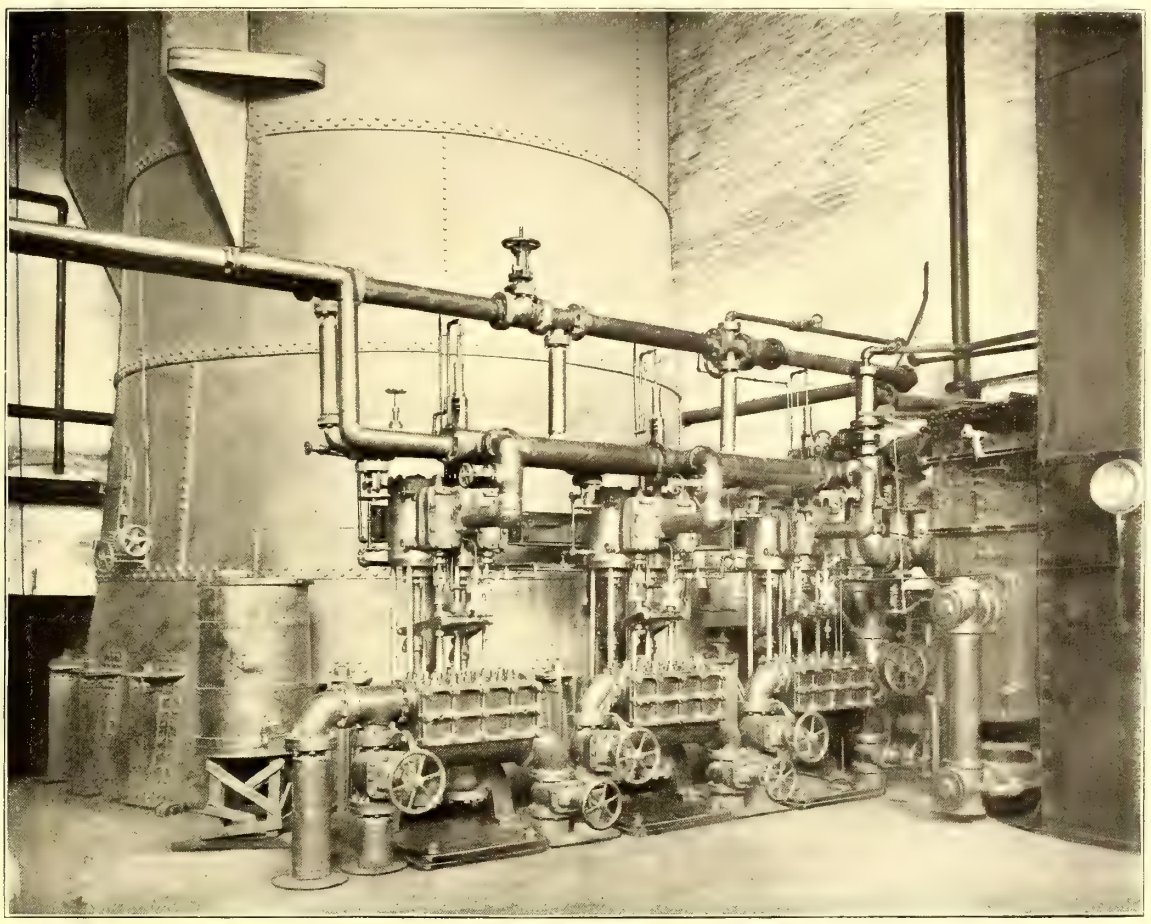
COOLING TOWER, NEAR POWER STATION, SOUTH SIDE ELEVATED RAILWAY

BOILER ROOM, SOUTH SIDE ELEVATED RAILWAY

of the Union Consolidated Company, and the Cicero & Proviso and Chicago Electric Transit Companies stations.

Chapman high and low pressure valves are used in several of the elevated railway stations, and in those of the Union Traction Company and the Chicago City Railway Company. In some of the Union Traction stations and in the Northwestern station are also a large number of 18-in., 22-in. and 30-in. valves of the Ludlow Manufacturing Company.

The Siegrist Lubricating Company has installed a plant for oiling all of the engines and generators of the Metropolitan West Side Elevated Railway Company.



The Reynolds Corliss engines, of the Allis Company, are used in the stations of all the elevated railway companies of the city except the Lake Street and Union, and in the Hobbie Street and Cicero & Proviso stations. Between 3000 and 4000 h. p. in all have been installed for railway service in sizes ranging from 1200 h.p. to 2500 h.p. The Wheelock and Green Wheelock engines to the extent of 25,000 h.p. are used in the Chicago City power stations, and in the Edgewater plant of the Chicago Consolidated company, now closed. The

Fraser & Chalmers engines are now used in the Western Avenue and California Avenue stations, the Buckeye and Ball in the Calumet station, and Pennsylvania Iron Works and George H. Corliss in the Western Avenue station.

Twenty-six generators with an aggregate capacity of nearly 15,000 kw. have been furnished to the power stations of Chicago by the General Electric Company, sixteen generators with a capacity of about 11,000 kw. have been furnished by the Westinghouse Company, and nine generators with a capacity of 7500 kw. have been furnished by the Siemens & Halske Company.

In the auxiliary steam apparatus we find represented the Baragwanath, Hoppes, Berryman, Reynolds and Wainwright feed water heaters; Chapman, Crane, Jenkins and Ludlow valves; Worthington, Blake, Deane, Weir and Craig pumps; Rooney, Murphy, Link Belt, McCaslin, Babcock & Wilcox, Hunt, Jeffries and Borden & Sellers furnaces, grates and stokers; the Siegrist lubricating system; and the DeRycke grease extractor.

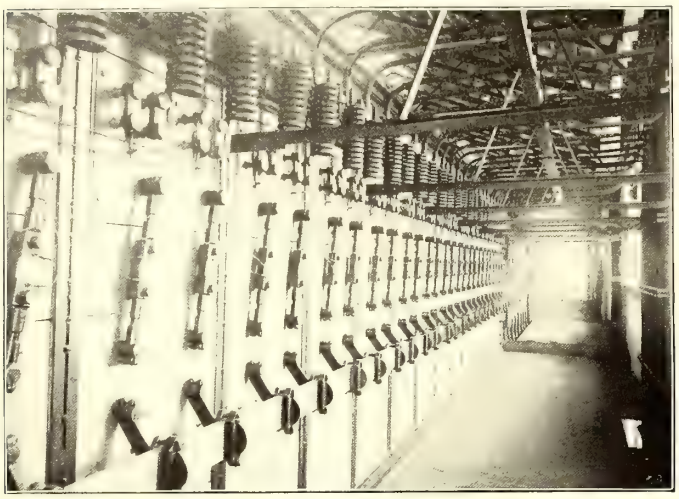
The kind of coal used chiefly in Chicago is the Indiana screenings, which costs from $1.12 to $1.30 per ton.

PUMPS AND FEED WATER SYSTEM, SOUTH SIDE STATION

OVERHEAD CONSTRUCTION IN CHICAGO

The overhead structure in Chicago is simple in design, is well put up and is durable. There has been no attempt at over-ornamentation of poles, but the entire structure is as inconspicuous as is possible to obtain. Iron poles weighing from 900 lbs. to 1200 lbs. are used, with wood poles through the "alleys" between streets.

The standard trolley wire of the Union Traction Company is No. 0 hard drawn copper, and the standard guard wire is No. 6 silicon bronze. In the business district silicon bronze is also used for span wire, while in the suburbs 5-16-in. stranded galvanized wires are used. Ætna insulation is used throughout with line material made by Albert & J. M. Anderson, the originators of the Ætna insulation.



The Chicago City Railway Company formerly used No. 0 trolley wire, but now uses No. 00, both because of its mechanical strength and because of its assistance in helping out the general feeder distribution system. A span wire consisting of ⅜-in. seven strand galvanized iron cable is used at all places, but there are no guard wires on the Chicago City system, as they are believed to be a menace to life and property, and in all cases where they were formerly installed they have been taken down.

In the engravings pages 630-631 are shown all types of line material ever used on the Chicago City system, the engraving, Fig. 5, showing the material selected as the company's present standard. The following description of these standard pieces will well illustrate the latest development of overhead line material and the reasons for some of the mechanical details which have been devised.

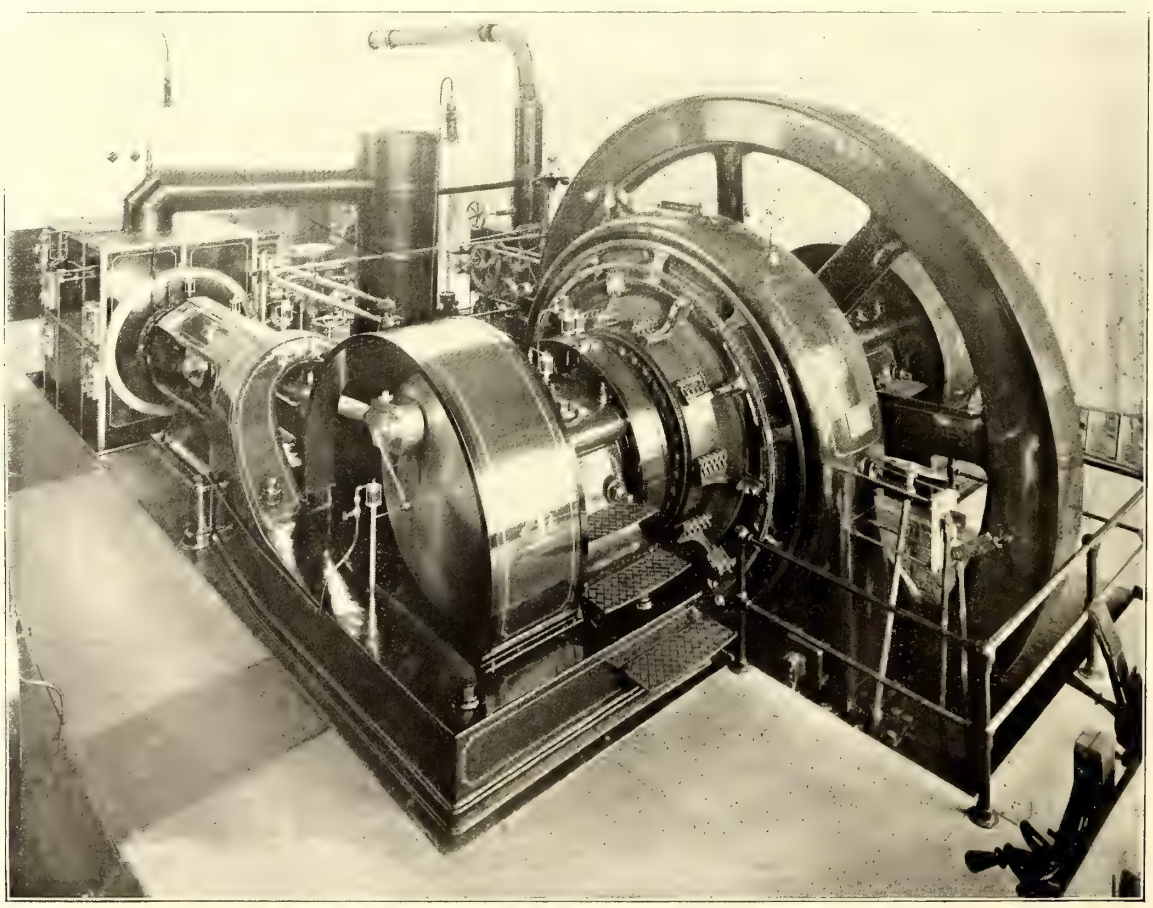
Brass is employed in all of this material with one or two exceptions, and iron is in no place made to join iron, even where it is necessary to let an eye bolt, for example, into a brass core. Malleable and other iron material in overhead work has been practically abandoned because of its rapid deterioration and loss in cross section by rust, and also because it was found that the rust spread over the insulating material, causing short circuits. Brass is not affected by the weather, and when broken or discarded for any reason can be melted down, and is found cheaper in the long run than iron.

While the high insulating qualities of rubber are recog-

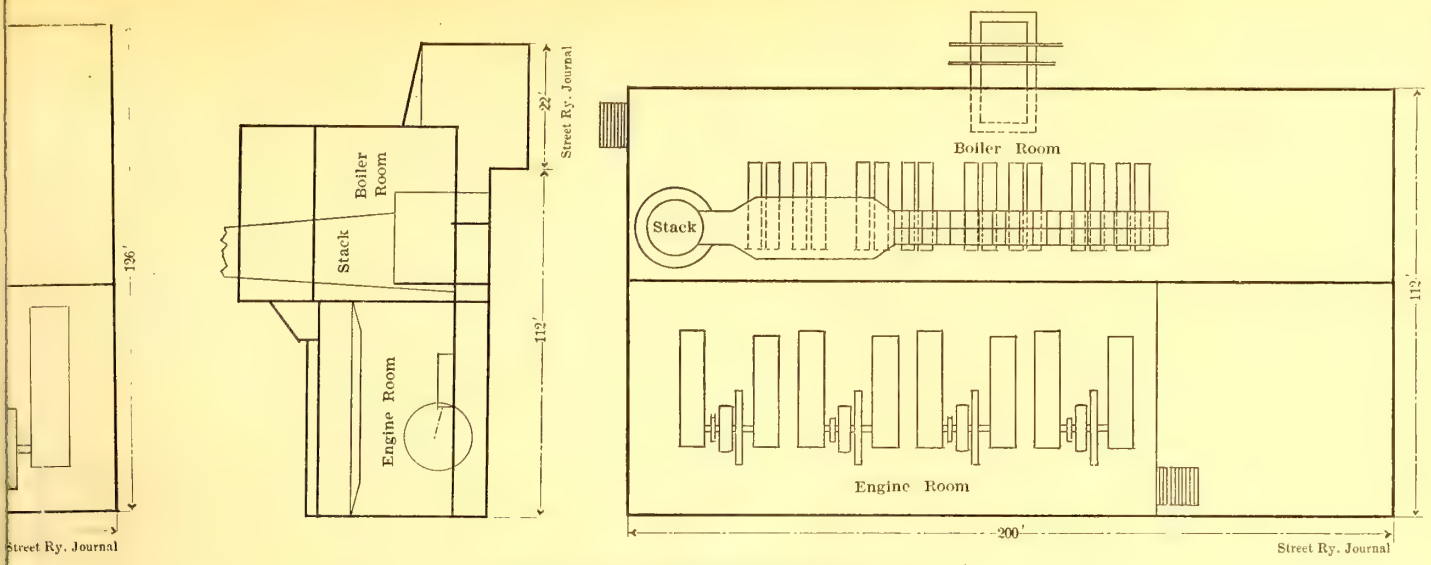
nized, particularly in places where it can be kept free from air and moisture, it is found in the Chicago City Company's practice that on exposure the surface cracks, and after a short time these cracks become filled with coal dust, soot

BACK OF SWITCHBOARD, CHICAGO CITY RAILWAY STATION

and other particles which serve to conduct the current around and across the insulation. The company's standard insulating material, therefore, is red fibre for switches and cutouts, and Ætna insulation for all other appliances, the Ætna being regarded as the best in use. Three insulations between the trolley wire and the ground are made in all cases, the first being a fibre spool in the pole band (Fig. 5, No. 41); the second, a similar insulating spool (No.50), attached to the first by a 3-ft. strand of galvanized iron wire, and the third, the regular straight line hanger (No. 19). This consists of an insulating bolt (No. 20), and a wood piece (No. 57).

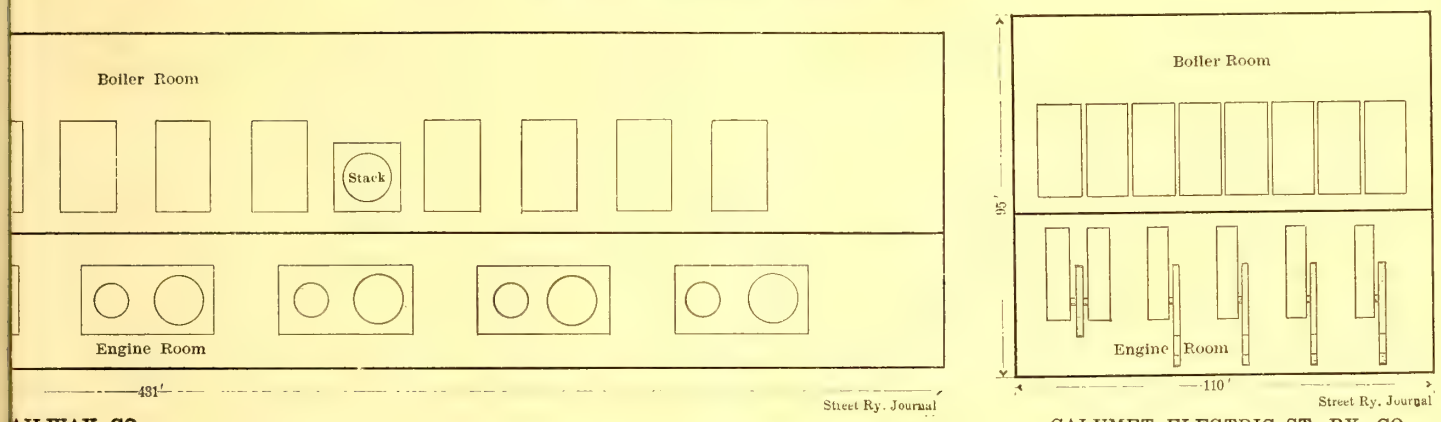


In splicing two pieces of trolley wire, their ends are brought to the splicing ear (No. 17), and bent up therein through holes, leaving a smooth run for the trolley wheel. No solder is used either in splicing or attaching straight line hangers, but only for connecting feeder cables. The heat necessary for the use of solder is found to anneal



COOLING TABLES, CALUMET STATION

trolley wire, weakening it and making it liable to crystallization and breakage.



When trolley wires are strung in ordinary summer weather, or when the temperature runs about 75 degs., a sag of 8 ins. or 10 ins. is allowed in all spans of from 115 ft. to 120 ft., but in cold weather from 5 ins. to 6 ins. of sag only are allowed. The average height of the trolley wire above the ground is from 19 ft. to 19 ft. 6 ins., except at railroad crossings, where it is from 22 ft. 6 ins. to 23 ft. A

method of supporting the trolley wire from the elevated structure at a point where it passes over a railroad track is shown in Fig. 1.

Clinch ears are employed, as they are not likely to let the wire down, while on curves they will move slightly on the wire if the trolley pole catches in strain wires, and thereby prevent the pulling down of the line, as might sometimes occur.

Tubular iron poles are in all cases employed in new construction, lattice poles having been discarded. The standard straight line pole consists of three sections, 7 ins. 6 ins. and 5 ins. in diameter, which weighs from 850 lbs. to 900 lbs. Corner poles are 8 ins., 7 ins. and 6 ins. in diameter, and some extra strain poles weigh as high as 1200 lbs. In setting the pole, its base is treated by a preservative paint, composed of tar and other mixtures. It is then imbedded in concrete to a depth of 6 ft. or 7 ft., and the bottom rests on a hard wood board 12 ins. long x $1\frac{3}{4}$ ins. thick. At the street surface an iron thimble 12 ins. long encircles the pole and is imbedded in the concrete. The hole of this thimble is an inch larger in diameter than the pole which it contains, and when the latter is set in position, the space is filled with cement up to a flange in the thimble, so that a slanting roof of cement is made all around. Cement is preferred to tar, as the latter is apt to shrink and crack, thereby allowing water to reach the iron and rust it.

Where the poles are rusty, they are first scraped with steel brushes and painted. The first coat is a red paint, which is followed by a coat of graphite. A coat of paint lasts usually about three years, except on lines near the Chicago River, where the gases from the foul water in the river cause the poles to deteriorate rapidly. It is worthy of note also that the trolley wire on lines adjacent to the river oxidize much faster than others, and a bright copper wire tarnishes in half an hour after being strung in this neighborhood.

Poles are repainted every three or four years, and are stated to have a life of twenty or thirty years, the annual depreciation being regarded as about $3\frac{1}{2}$ per cent to 4 per cent, while cedar poles are said to depreciate at the rate of $6\frac{1}{2}$ per cent to 7 per cent per year, having a life of only fourteen or fifteen years.

An iron cap is placed at the top of each pole, and there is an ornamental cast-iron ring at each joint. Ordinarily, the pole band (Fig. 5, No. 41) is placed 10 ins. from the top of the pole. On some lines the poles carry an ornamental hanger for supporting electric lamps, these being installed and maintained by the city. Cross arms are of wood, with supporting iron brakes.

After trying nearly all kinds of trolley line switches on the market, a standard (Fig. 5, Nos. 9 and 12) has been adopted. No. 9 shows a "Y" shaped, and No. 12 a right-hand switch, with the corresponding left-hand. No. 1 is an insulated cross-over. This is composed of a section of red fibre 1 in. x 3 ins., and in adjusting it, it is not necessary to cut the trolley wire, as the wires of both lines can be led over the insulated portion, one above the other. A burn-out has never occurred with this style of cross-over on the Chicago City system. In Nos. 37 and 40 are shown two forms of live cross-overs; No. 40 is a design for ordinary right-angle crossings and has a small circle, while for the acute crossing, No. 37, the circle is larger. The

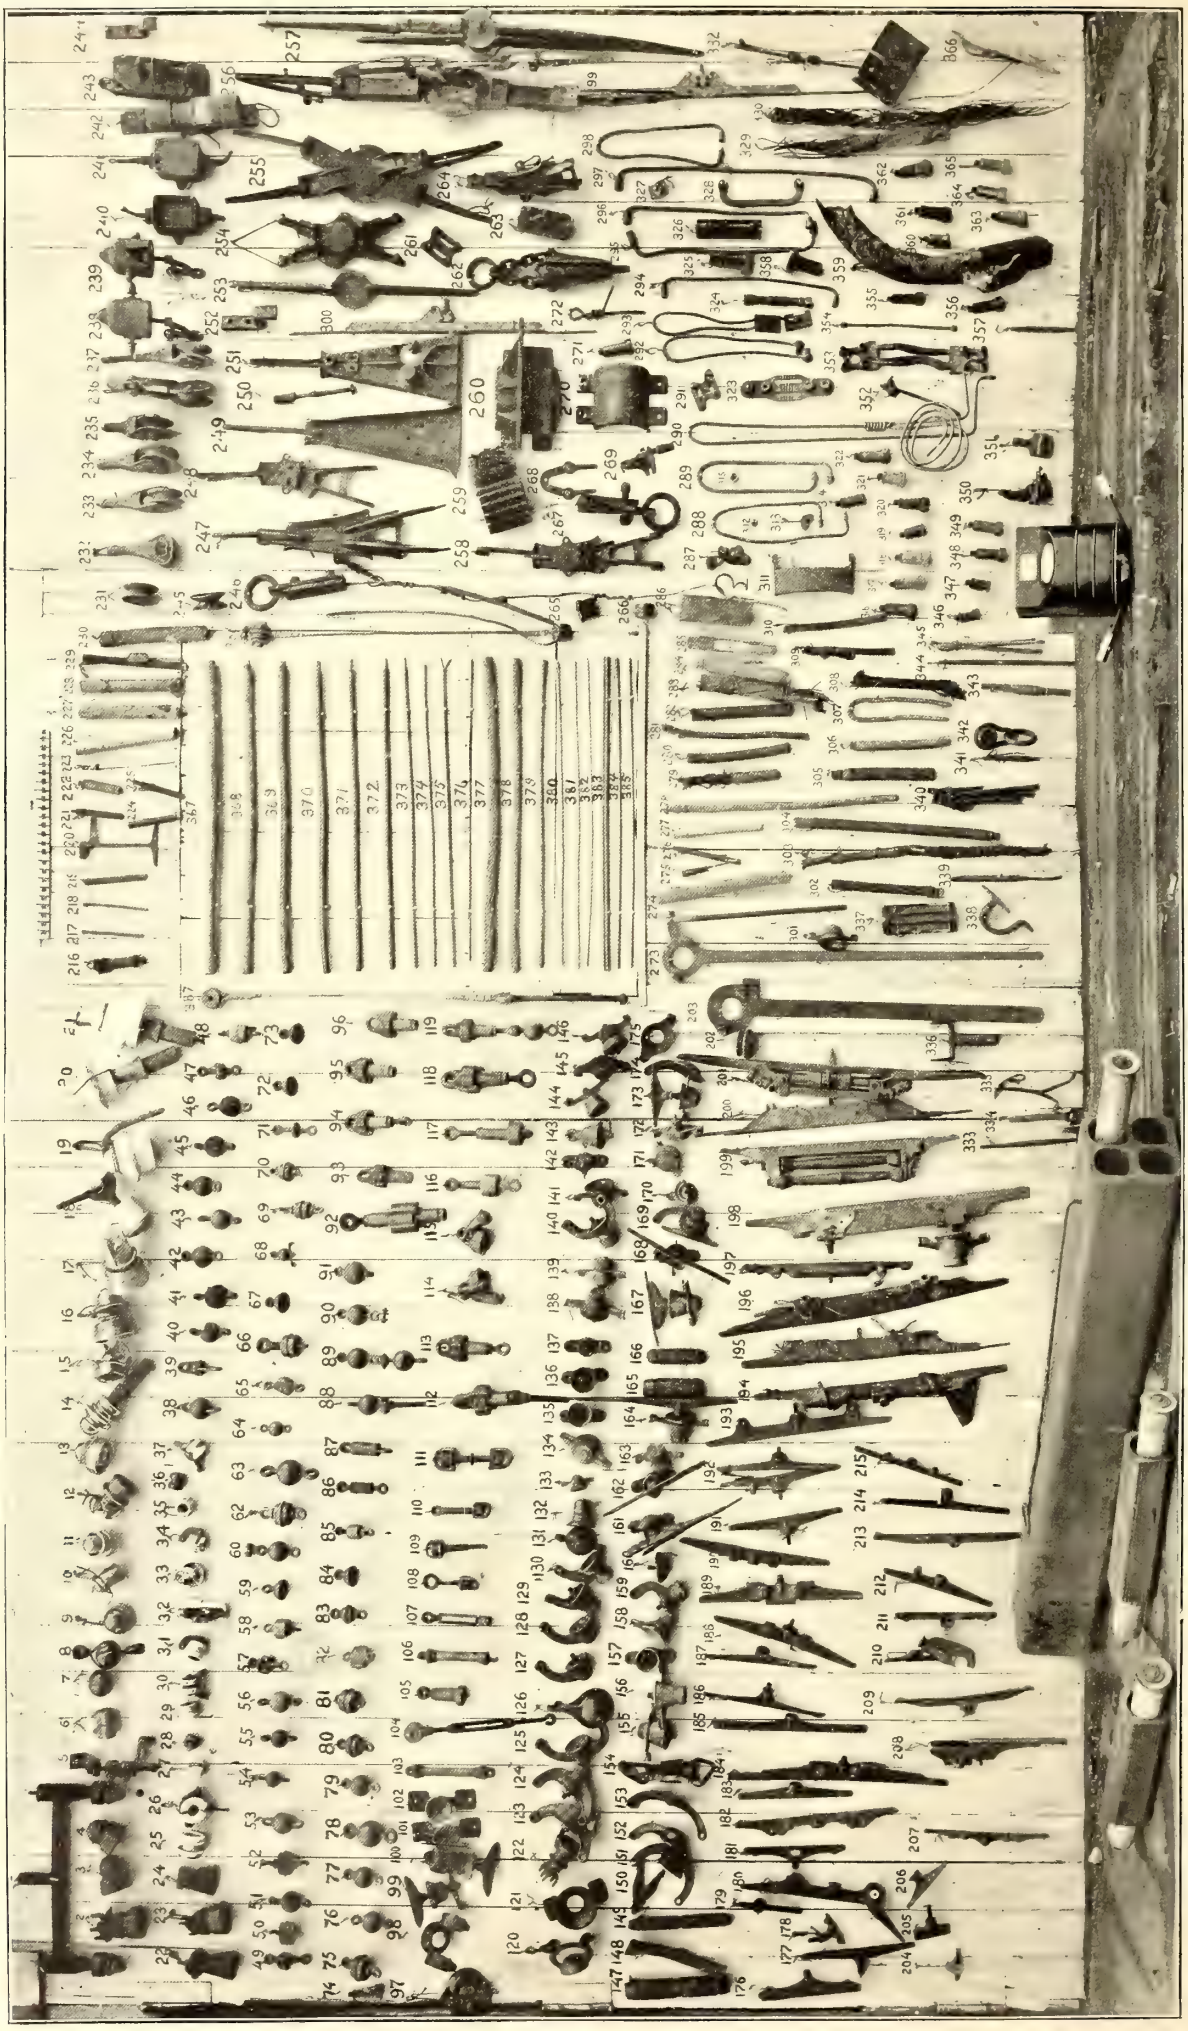

FIG. 4.—OVERHEAD LINE MATERIAL, PAST AND PRESENT PRACTICE, CHICAGO CITY RAILWAY

section insulator shown at No. 52 is of the same style of construction as the insulated cross-over, but has a hood to protect the fibre from the action of sleet and water.

At all section insulators and at insulated cross-overs, metal targets, shown at No. 22, are employed. These are in the shape of an incandescent lamp and are painted red

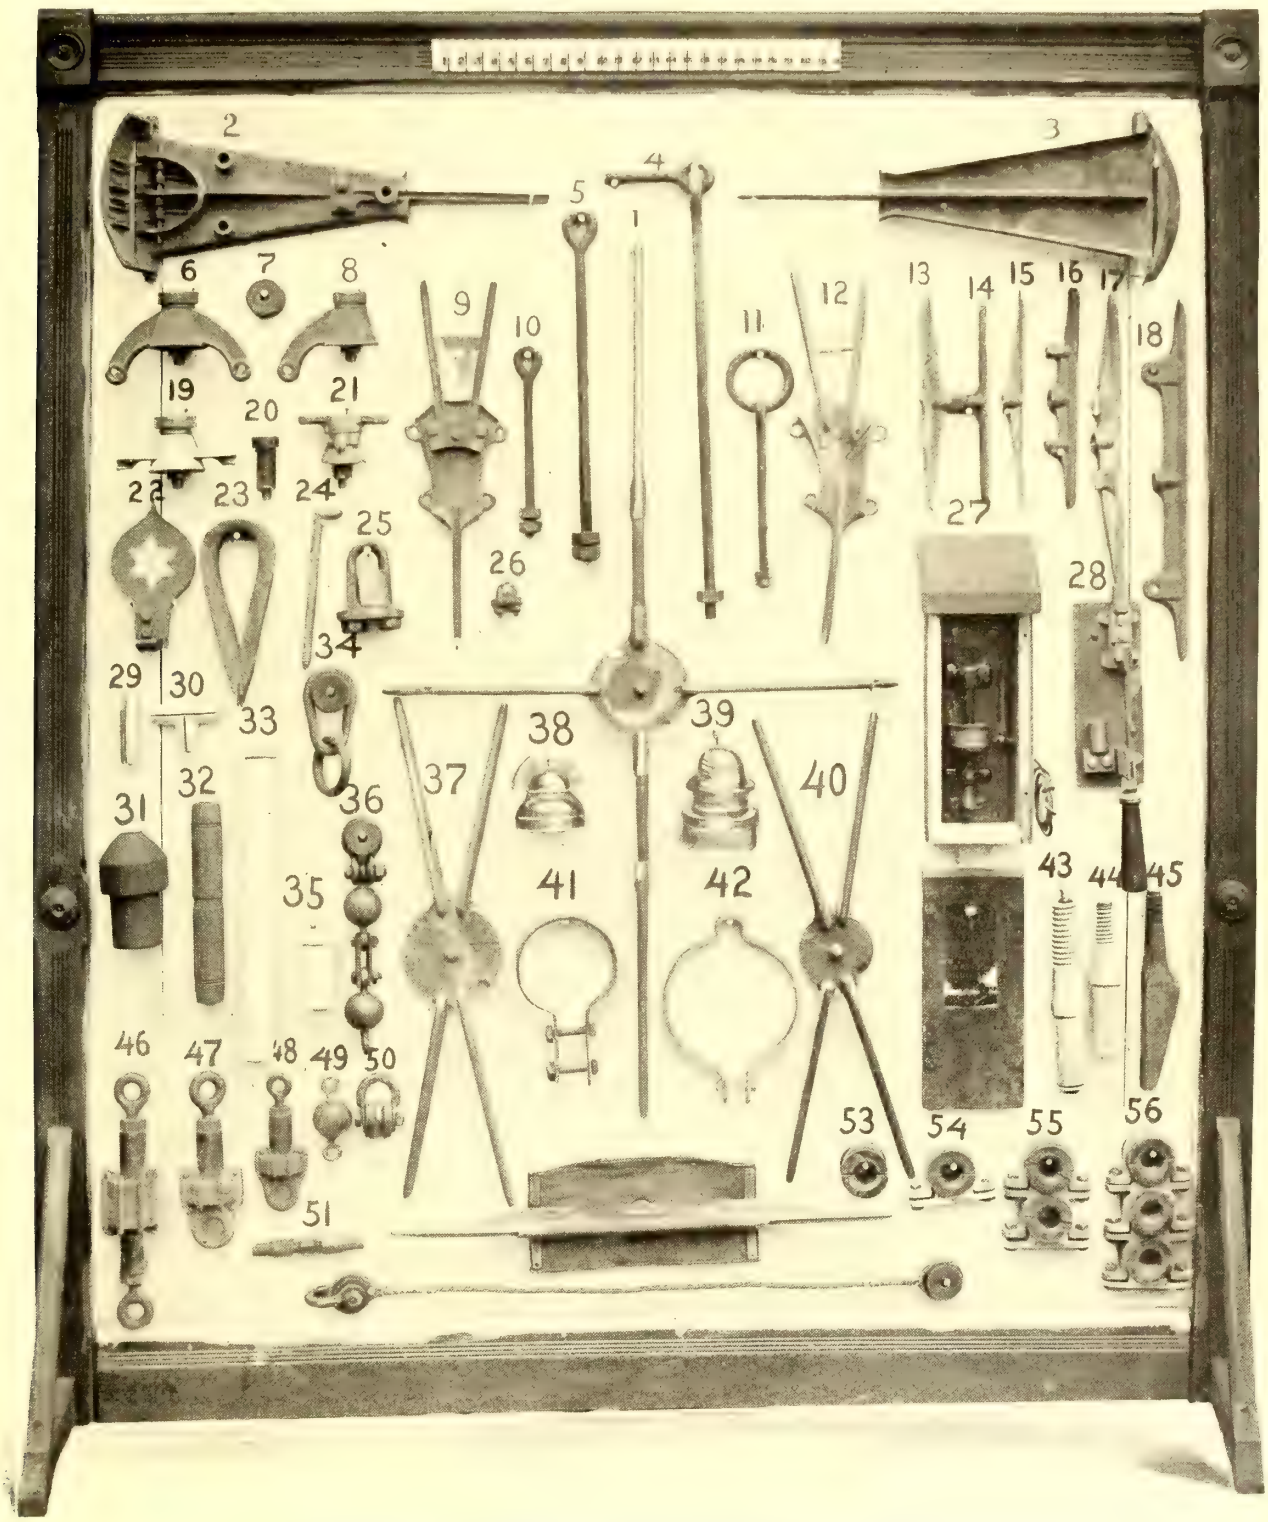

FIG. 5.—OVERHEAD LINE MATERIAL, PRESENT STANDARD, CHICAGO CITY RAILWAY

with a white star in the center. They are clamped to the span-wire or trolley wire at the section, and at these points the motorman is required to throw off the current in passing. This is in order to prevent the fibre from being injured by the arcing which would be caused were the run made with full current.

Lightning arresters are, as a rule, installed at every half-mile of double track or every mile of trolley. These are placed on the poles and grounded. The Garton type of arrester is mostly employed, although experiments have been made with all the commercial types. The arresters are frequently inspected, and in many of them a sheet of paper is inserted between the points, which is often found to be perforated, showing the good work of the arresters. Yet with all the precautions the atmospheric currents sometimes get by and damage the motor armatures or burn out the insulation of the underground lead-covered cables. This has occurred to the underground cables where arresters were placed on each side of the point at which the cables were led from the underground ducts up into the line.

Return feeders are in two sizes, one a 350 000 c.m. cable

and the other a 211 600 c.m. cable. The 500 000 c.m. sections are regarded as too heavy, and hard to maintain on poles. Considerable cable is employed with a jute insulation treated with tar, resin, etc. The company's standard, however, is the lead-covered cable with rubber insulation, of which there has never been a foot lost from the burning out of the insulation. The cost, however, is about 25 per cent more than the cables in which other insulation is employed.

The underground cables are enclosed in conduits of vitrified material, and both single and multiple ducts are employed. The four-duct sections are made in 6-ft. lengths.

In installing the return circuit cables on all sections within 2 or 3 miles of the power houses, 25 per cent to 30 per cent more copper is employed in the return than in the outgoing section. This is regarded a necessary allowance as a substitute by a number of companies, but it may not be generally known that the largest actual installation of it so far made is on the new Northwestern Elevated Railway, which has purchased 150,000 lbs. of aluminum feeders, of which 75,000 lbs. are now in position. This wire is of 1,300,000 c.m. sectional area, and is used uninsulated. It is supported every 9 ft. and anchored. The chief difficulty with aluminum in the past has been a question of welding, but this difficulty is said to have been entirely overcome in Chicago, though the process is a secret one. The metal is, of course, non-corrosive and is considerably cheaper than copper at present prices per unit of carrying capacity.

The Calumet Company is finally coming back to wood as an insulation material for hangers and strain poles. The bell shells are cast as in ordinary service, and the shell is then filled with a wooden block held in position by an ordinary bolt. The wood employed in the hangers and porcelain ears is first soaked in kerosene and then boiled in paraffine wax.

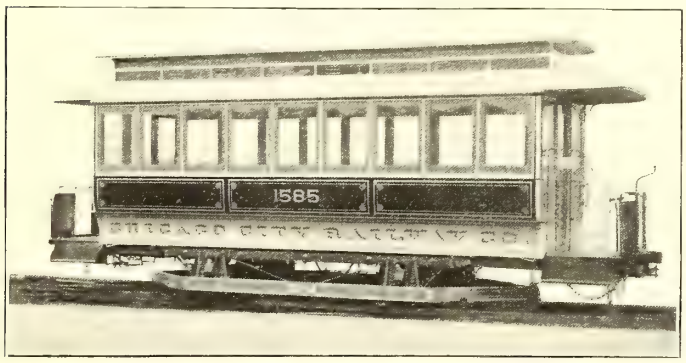

FIG. 6

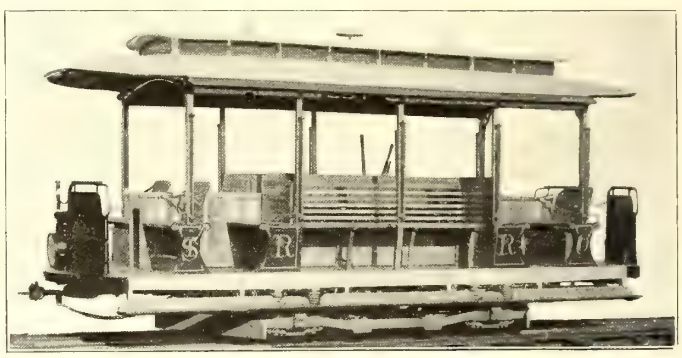

FIG. 7

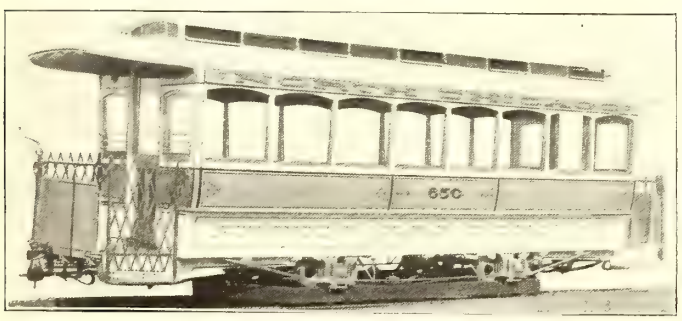

FIG. 8

FIG. 9

SOME TYPES OF CHICAGO CABLE AND ELECTRIC CARS

for safety, and to prevent electrolysis in neighboring substructures, no complaint from this cause ever having been charged against the system.

In connection with the line material should be noted the construction and repair wagons employed by the electrical department. Four of the tower wagons are shown in Fig. 2, and as will be noted, these are very substantial structures built to accommodate a large amount of material. The box-like body is provided with a door at the rear and is equipped with shelves and receptacles for different classes of material. The illustration shows the wagons as they are just starting out from the electrical storage yard. A pole raising wagon and water tank for concrete mixing is shown in Fig. 3. This pole raising wagon is employed not only for raising poles, but also for loading and unloading the reels from the wagons illustrated in the large figure.

The high price to which copper wire has lately been carried has led to the serious consideration of aluminum

ROLLING STOCK IN CHICAGO

The visitor to Chicago will not be impressed with the cars of its surface railway system, for, truth to tell, the number of new and modern cars is far exceeded by that of types which are rapidly passing away, among these latter being practically the entire equipment of grip cars, together with most of the horse cars which they have in tow, for many of the principal lines are still running by the cable system, as above stated. As these cable grips and trailers form so large a proportion of the whole rolling stock of the surface system, it may be well to briefly refer to them in passing because of the good service they have done.

The standard grip and trail cars of the North and West Side systems are shown in Figs. 7 and 8. The grip car

is entirely open and the gripman, placed in the center, has an unobstructed view both in front and behind. His box has an aisle or extension toward each platform, and on each side of it are longitudinal seats, entered from the side, while at each end are two seats with stationary backs, and opposite the latter a seat with reversible back. This grip car is used by smokers both winter and summer, and has been quite popular. The trail car has a 21-ft. body, with Brill equalizing running gears. A guard entirely surrounds the wheel and is carried by the axle boxes.

At an earlier date the same companies purchased a number of double truck cars of the type shown in Fig. 9, these being a combination open and closed car, with a gripman's box similar to that in the small grip car. A car of this sort, of course, requires a loop at the end of the road.

The Chicago City Railway Company's closed trail car is shown in Fig. 6. These have 21-ft. bodies and are slightly more than 6 ft. wide. They have the usual Chicago guard surrounding the wheels and the Brill equalizing running gear. All of the cars just described were made by the J. G. Brill Company.

The latest purchases of cars by the Chicago surface companies are shown in Figs. 10, 11 and 18. Fig. 11 represents an electric motor car, of which 100 were made for the Chicago City Railway Company by the John Stephenson Company, while sixty more of a similar pattern are being built by the St. Louis Car Company. These cars are 20 ft. long over corner posts and 30 ft. over all, and are 6 ft. 2 ins. wide at wheels and 7 ft. 6 ins. at belt rail. The platforms are 4 ft. 6 ins. long and are enclosed by vestibules, having three drop windows angularly placed. The front of the vestibule is curved below windows, and is faced with sheet steel. The platforms have entrances at both sides and are fitted with three doors folding against the vestibule. The steps are pressed steel with rubber treads. The platforms are fitted with angle iron buffers.

The window frames in this car are set in special molded rubber pockets to prevent all rattling whatever. The interior finish is in cherry, stained dark, with hand carved window and door pilasters and pressed moldings. The ceiling lining is bird's eye maple veneer. The seats are the Hale & Kilburn convertible type, with spring cushions and backs, covered with olive green carpet. The metal trimmings are extra heavy bronze throughout. These cars are painted in olive green in varying shades, the deck sash being set in green rippled glass to match. On the hoods are Hunter illuminated signs. The cars are wired for conductor's signal with buzzers on each platform and push buttons in the window pilasters. The weight of the car body is 9000 lbs., and it is mounted on a Moore electric truck, with 9-ft. wheel base, equipped with Price power brakes.

FIG. 10

FIG. 11

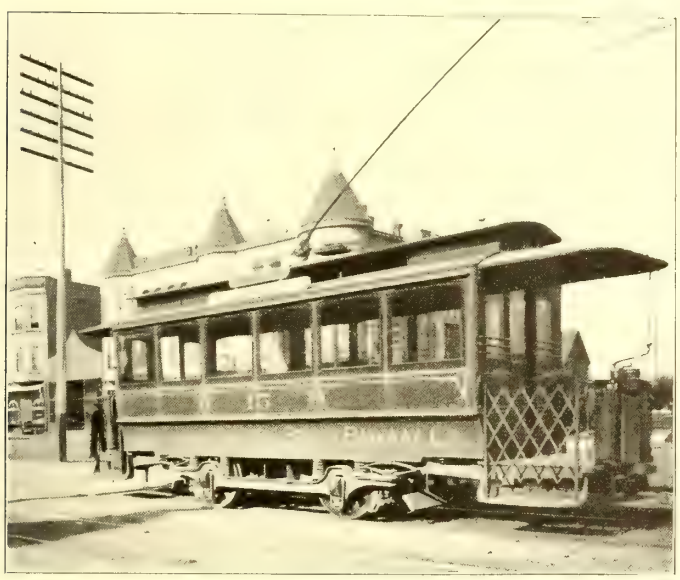

FIG. 12

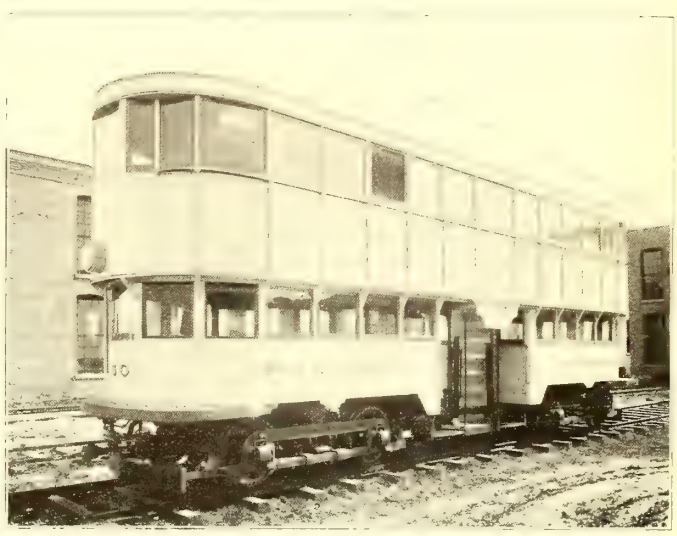

FIG. 13

SOME TYPES OF CHICAGO ELECTRIC CARS

In Fig. 10 is seen a type of electric motor car recently furnished to the North Chicago Street Railroad Company by the J. G. Brill Company, and in Fig. 18 is one of the latest suburban cars built for the Chicago, Harvard & Geneva Lake Railroad Company by the Jackson & Sharp Company. In Fig. 12 is shown the closed motor car of the Calumet Company, and in Fig. 13 a special double-deck Pullman car of the Chicago General Railway Company. In Fig. 44, page 645 may be seen the new cars just completed by the Pullman Company for the Northwestern Elevated Railway Company, and in Fig. 48 some of the details of construction. In Fig. 19 is shown one of the cars of the South Side Elevated Railway Company, built by the Jackson & Sharp Company.

The Chicago surface railway companies were among the first to appreciate the value of the independent motor truck, and the West Chicago Company alone purchased about 900 Brill trucks adapted for cable car use when they were first designed. Of the independent electric motor trucks used in Chicago, nearly 1300 are of the McGuire type, 1000 of the Brill 21 type with solid forged frame, and a considerable number of the Peckham type, including thirty-two "special elevated trucks, type 14A extra strong," on the South Side Elevated Railway.

The Moore truck is the standard of the Chicago City Railway Company. It was designed by C. E. Moore, the company's master mechanic, and is built by the Dorner & Dutton Company. It is described in full in the Street Railway Journal for October.

In Figs. 20 and 21 are shown the types of Westinghouse motors chiefly used by the Chicago roads, and in Fig. 22 the types of General Electric motors. Without going into too great detail, a general idea of the condition of the Chicago electrical car equipment as a whole may be obtained from the following statement of the relative numbers of the different types now in use:

General Electric Motors:		
Type	H.P.	Number in Use.
G. E.-800	25	1,688
G. E.-2000	125	118
G. E.-55	150	110
G. E.-1200	50	52
G. E.-57	50	40
G. E.-52	27	30
W. P.-50	25	30
W. P.-30	15	8
All types		2,076
Type K controllers		1,984
Type L controllers		202

Westinghouse Motors:		
Type	H.P.	Number in Use.
No. 3	25	237
No. 12	25	548
No. 49	35	145
No. 47	35	2
All types		932

In addition to the motors of these two companies there are some 200 30-h.p. and 50-h.p. Siemens & Halske motors in use, and a number of Walker motors.

In behalf of the Lake Street Elevated Railway Company, J. R. Chapman, electrical engineer of the North and West Sides systems and of the Lake Street and Northwestern Elevated Railways, made a series of careful tests for the purpose of determining the motor equipment best adapted for the Lake Street Elevated Railway, and through Mr. Chapman's kindness the results of these tests are reproduced herewith. The type finally selected was the G. E.

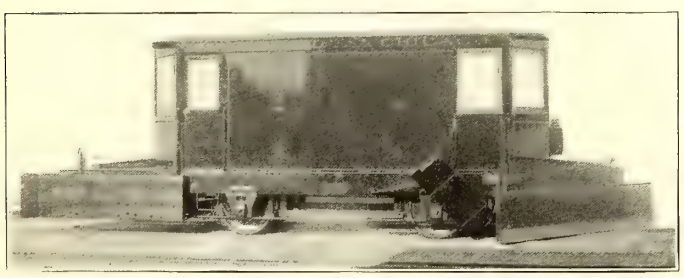

FIG. 14.—STORAGE BATTERY SNOW SWEEPER

FIG. 15.—WEST CHICAGO SNOW SWEEPER

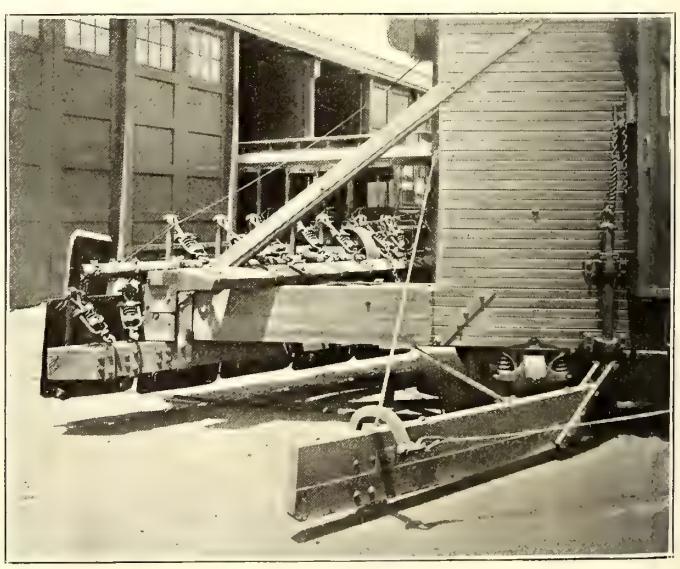

FIG. 17.—SIDE VIEW, CALUMET ADJUSTABLE SNOW SWEEPER

55 (.150 h.p.) motor, with type L controller, illustrated in Fig. 22.

Figs. 16 and 17 show a snow plow designed by H. M. Sloan, general manager of the Calumet Electric Street Railway Company, which has quite a number of novel features. The nose of the plow is composed of steel plates arranged in sections and supported by means of bars which have a spring attachment and permit each individual plate to rise independently of the others in case a partial obstruction is encountered, so that damage to the nose and to the bar is prevented. The height of the plate from the pavement is adjusted by means of a hollow shaft about 5 ins. in diameter, which is operated by means of a chain attached to a quadrant in the shaft, and adjusted about a windlass in the back. The wings, or side flukes, are also attached to the bar. By a spiral spring and wire rope, as shown, this provides an elastic support, so that if any obstructions are met with underneath, the wings yield without undue strain or danger of breakage, and after passing the obstruction they return to position. Plows constructed on this principal were in continuous service in the winter of 1897-8 for seventeen days, removing badly drifted snow from the tracks and were not once brought in for repairs nor did they suffer serious damage during that time.

A large double end snow plow for heavy drifts is also employed by the Calumet Company when necessary. This is provided with a pilot having a one-sided oblique mold board, so that it throws the snow nearly all to one side. The short side is only 5 ins. or 6 ins. wide, but is built back and terminates in a square side, so that it rests against the end of the snow bank and prevents the plow from being derailed by the unequal pressure. Side flukes are attached by means of the same kind of spiral springs and wire ropes as those just described.

Fig. 14 shows a storage battery snow sweeper built by the Brill Company for the Chicago Electric Traction Company. This is 19 ft. long and 6 ft. wide. The outside sills are fitted with $\frac{1}{2}$-in. iron, and each shear board has an extension wing. The shears themselves are operated by worms. The batteries are carried under the floor of the car between the wheels, which are 9 ft. 3 ins. apart.

The Brill Company has furnished the North Chicago Street Railroad Company some sixteen sweepers of the type shown in Fig. 15, and the McGuire Manufacturing Company has furnished twenty of its sweepers to the different companies of Chicago.

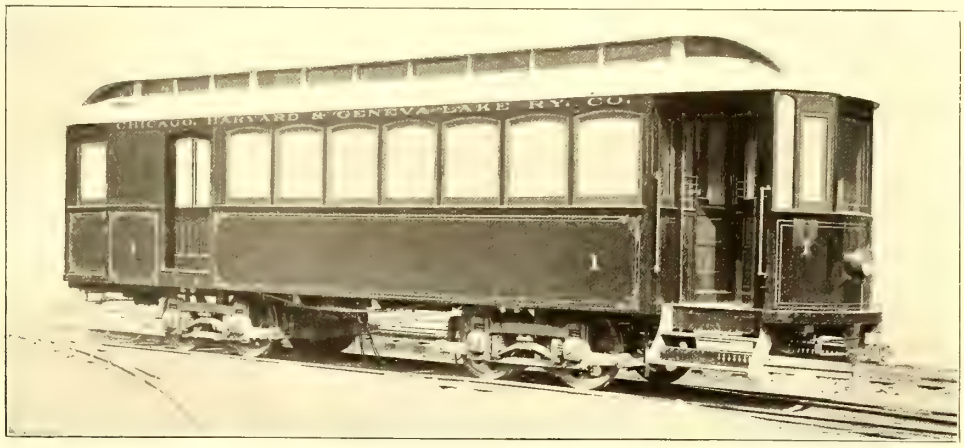

FIG. 18.—A CHICAGO SUBURBAN SURFACE RAILWAY CAR

Although trail cars are used so generally in Chicago, trains of two, three, four and even five cars being frequently made up for the heavy hours of the day, no attempts have yet been made to apply power brakes for the handling of these trains, except that on the Chicago City system a large number of the Price momentum brakes, manufactured by the Peckham Company, are used. On the South Side elevated lines, the Christensen brakes with independent motor compressors are used on all trains, and the same makes are also used to some extent upon the Metropolitan and Lake Street elevated trains, but the New York air brakes are used more largely on the Metropolitan. Electric brakes have not made their way into popular favor as yet.

FIG. 19.—A SOUTH SIDE ELEVATED RAILWAY CAR

About 250 of the Chicago City cable cars, 200 of the North Chicago cable cars, and 150 of the West Chicago cable cars are lighted by Pintsch gas. The surface and elevated electric cars are lighted, of course, by electricity.

Electric heating is quite general on the Chicago cars, both surface and elevated. The South Side cars are using the "Gold" heaters, the Metropolitan elevated, the "American" and "Consolidated" heaters, and the Lake Street the "Consolidated," while the new Northwestern has ordered "Consolidated" for its complete equipment. The latter are also used on practically all the surface lines, about 500 having been so far installed, while the North Chicago is also using the F type panel heaters of the American Electric Heating Corporation. The grip and trail cars of the Chicago companies are heated chiefly by the McGuire and Columbian stoves.

The Hale & Kilburn Manufacturing Company has furnished seats to about 2500 cars in Chicago, including 700

on the elevated lines and 1500 on the Chicago City lines. The car registers have been purchased chiefly from the Meaker Company, which has furnished some 2500 in all to practically all the street railways of Chicago. Curiously enough, the Lake Street Elevated Railroad Company is using 120 portable registers (manufactured by the

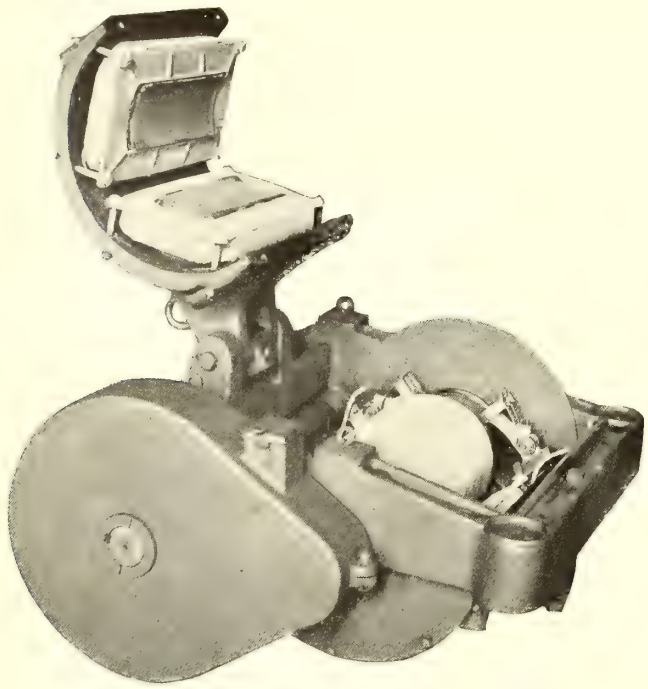

FIG. 20.—THE WESTINGHOUSE NO. 3 MOTOR

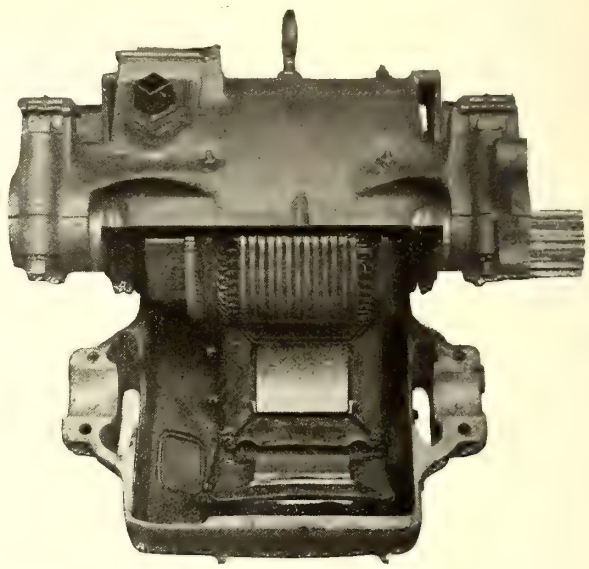

FIG. 21.—THE WESTINGHOUSE NO. 12A MOTOR

International Register Company), which is a novel practice in the operation of an elevated railroad. By this means they are able to do away with station agents almost entirely, except at the busiest stations, each guard or conductor collecting fares from those who go in at his gate, except at the stations where they have station agents.

In addition to the Meaker registers, a few Lewis & Fowler registers are used on the Union and Consolidated systems, the New Haven registers on the Calumet, and the International on the Chicago General.

The magnitude of traffic of the Chicago lines is well shown by the number of employees engaged in handling the cars. The Chicago Union Traction Company has over 900 motormen and gripmen and 1300 conductors, the Chicago City has nearly 750 motormen and gripmen and over 900 conductors, the Chicago Consolidated has 185 motormen and 200 conductors, and the Calumet Company has 90 motormen and 100 conductors.

ROADBED CONSTRUCTION IN CHICAGO

The building of electric railway track in Chicago has been along simple lines and with but little variation of practice. No concrete is used as substructure, but 7-in. and 9-in. girder rails are spiked directly to ties laid on dirt or on a light layer of broken stone or gravel at the bottom of an excavated trench. The standard construction of the Chicago City Railway is shown in the accompanying photographs and sections. This construction, on 6 ins. of broken stone, is used by the company for 10½ miles of track on Halstead Street. In the subconstruction recommended by the engineers of the Chicago Union Traction Company, which has, however, been used only on the Lake Street extension, oak ties 5 ins. x 7 ins. x 6½ ft. or 7 ft. long are laid 2 ft. apart from center to center, and ballasted to a depth of 8 ins. under the ties, the ballast being thoroughly rolled and strained to level and filled in between the ties.

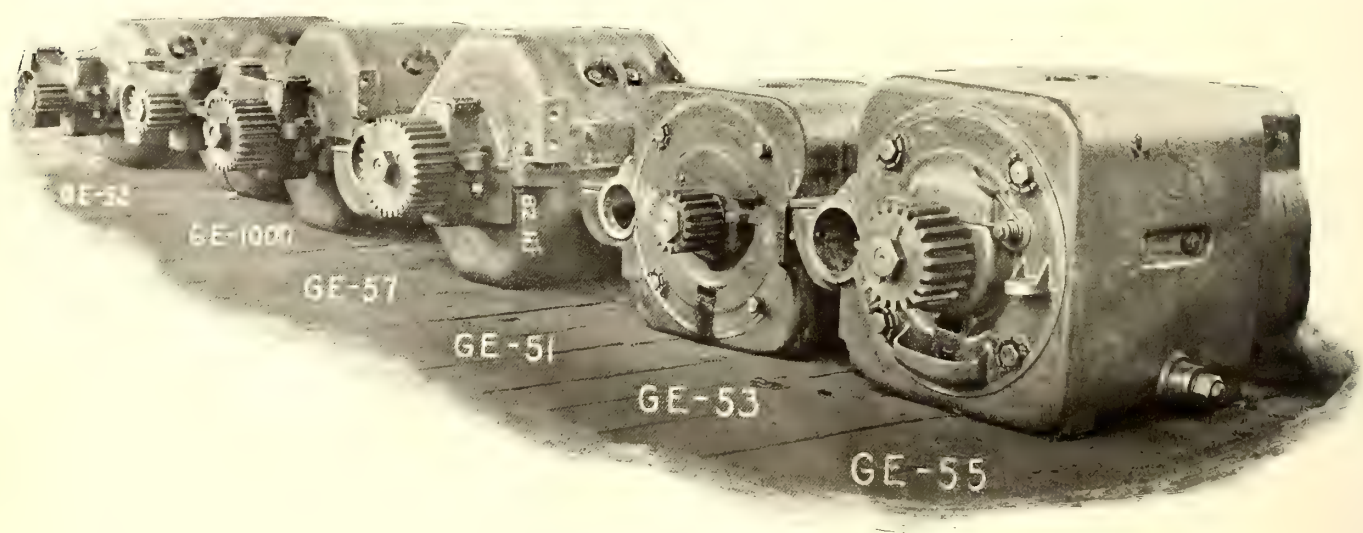

FIG. 22.—RECENT GENERAL ELECTRIC MOTORS

Speaking generally, it would seem as if enough attention had not been paid in the past in Chicago to a deep and durable substructure, for the soil of Chicago is moist even

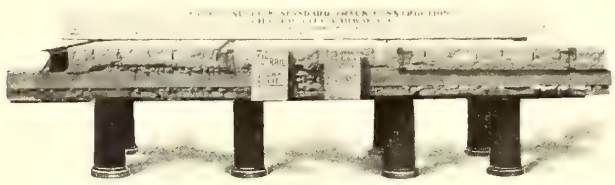
General method : Start from rest, run one mile and stop. Train : Motor car and two trailers.

to muddiness, and the track frequently shows evidence at the joints of insufficient strength of support.

Many rail sections have been used in times past, but practice is generally settling down to the section shown in Fig. 28, which is the Lorain Steel Company's 7-in. 85-lb. section. The same company's 9-in. 93-lb. section is also used in places as well as the 9-in. 90-lb. Cambria sections, ing to cast weld its future work by either the Falk or the "American Improved" process.

The Northwestern and Union Loop Elevated Railway Companies are using the Weber joint, following in this respect the practice of the Manhattan Company in New York. The Chicago Weber joint is illustrated in Fig. 47. It is 24 ins. long, with $4\frac{3}{4}$-in. bolts and nuts fitting A. S.



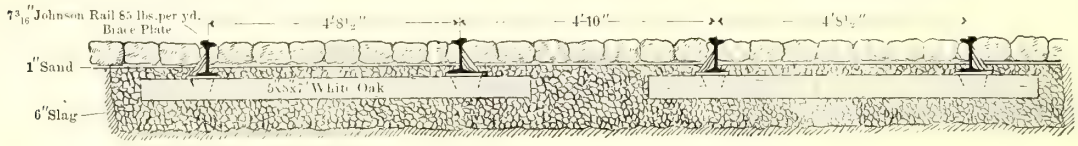


FIG. 23.—END VIEW

FIG. 24.—SIDE VIEW

CROSS SECTION OF THE CHICAGO CITY RAILWAY STANDARD ROAD BED.

Street Ry. Journal

FIG. 25.—CHICAGO CITY RAILWAY ROADBED

shown in Figs. 26 and 27. The elevated lines use an 80-lb. 5-in. T. rail of A. S. C. E. standard section. (Fig. 46).

All new purchases of rails by the Chicago surface companies specify 60-ft. lengths.

The Falk cast welded rail joint is the standard of the three large Chicago surface systems, and all have now C. E. section of the 80-lb. rail. About 48 miles in all have so far been fitted with the Weber joints.

As may naturally be supposed, there is an immense amount of complicated and most expensive track "special work" in Chicago. In addition to the great number of crossings, loops, curves, etc., of the street railway lines

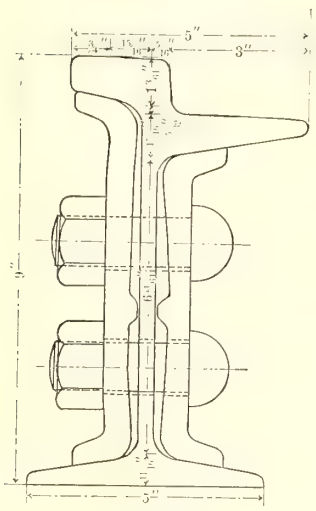

FIG. 26

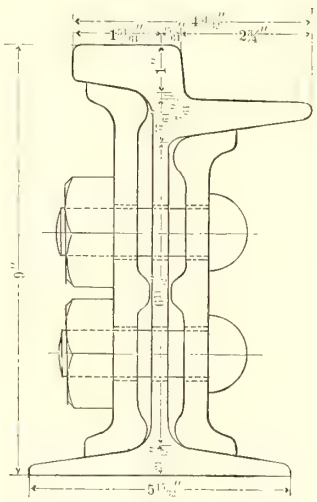

FIG. 27

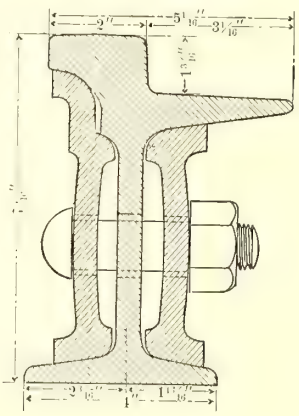

FIG. 28

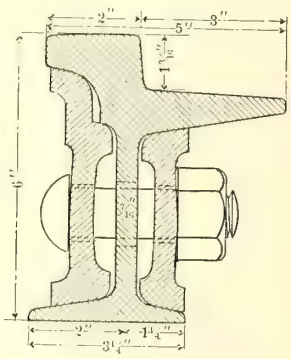

FIG. 29

RAIL SECTIONS AND JOINTS USED IN CHICAGO

taken out a license from the Falk Company to do their own welding. How carefully the details of the cast weld joints are worked out, both for old and new track, may be inferred from the number of the Falk joint molds used by the Chicago City Railway Company, as shown in the accompanying engravings. The Chicago City Railway Company was one of the first in the country to adopt this joint, about 40,000 joints being welded in 1895 and 1896, while there are now nearly 100,000 joints on its system. Complete welding outfits with licenses are now owned by the North Chicago Street Railroad Company, the West Chicago Street Railroad Company, the Chicago Consolidated Traction Company and the Chicago City Railway Company, and the Calumet Company reports that it is intend- proper, there are far more crossings with steam railroad lines than are ordinarily found in a city, Chicago being a great railroad center with tracks coming into the business heart of the city at grade in almost all cases. In addition to this, there are further complications from the crossing of cable lines with each other and with electric and horse railways, so that altogether Chicago is an excellent place to study how to solve complicated engineering problems in track construction.

For example, the Weir Frog Company not long ago made for the West Chicago Street Railroad Company two most complicated nests of crossings at Clinton and Randolph Streets and Clinton and Madison Streets. These crossings are of unusual length, the intersections between

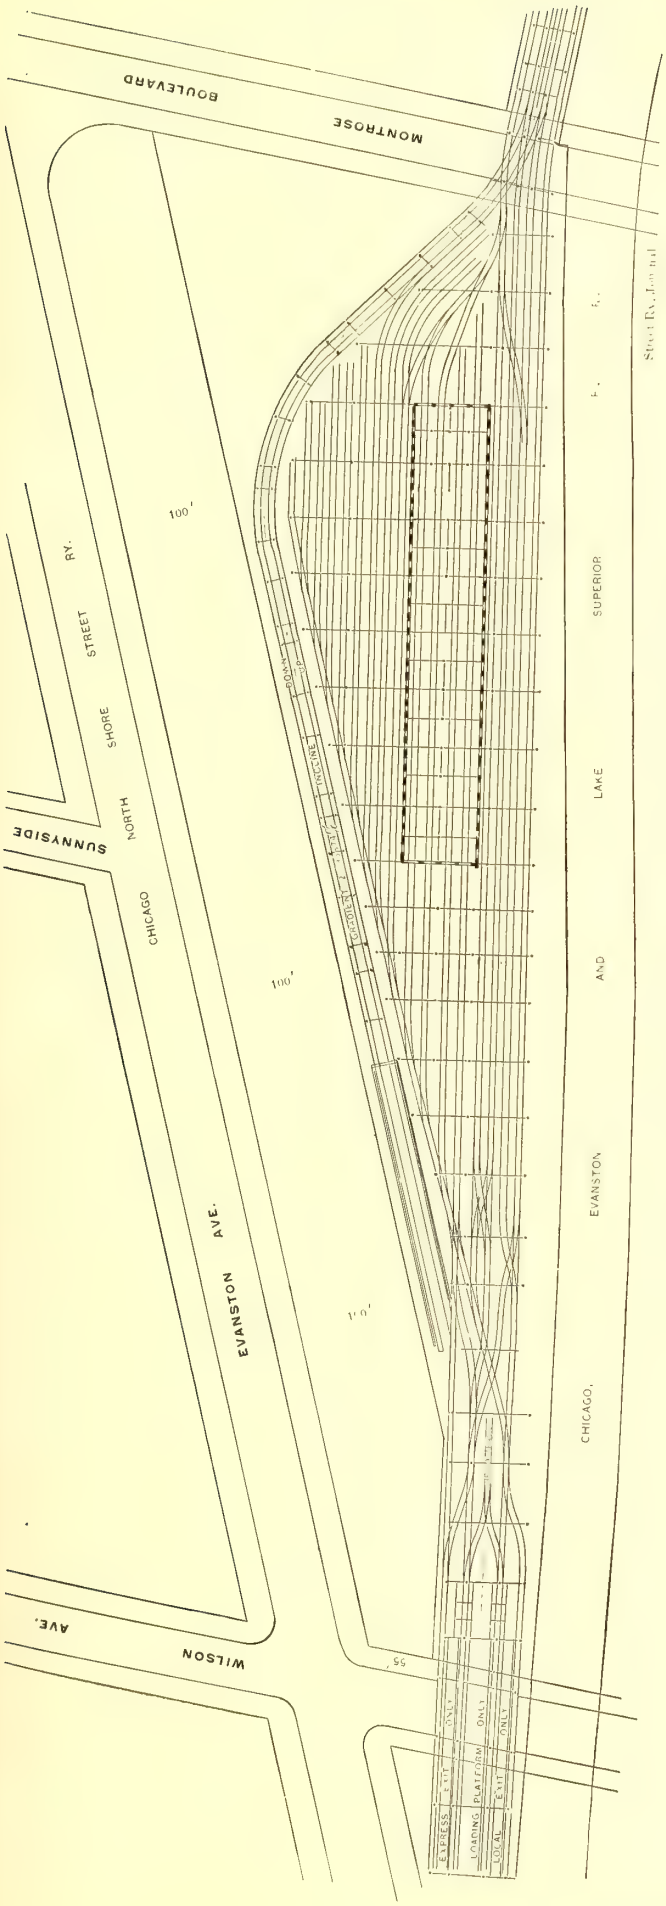

FIG. 30.—TRACK PLAN, NORTHWESTERN ELEVATED RAILWAY TERMINAL

switches measuring 130 ft., and between centers of opposite curves about 57 ft. Composing each set of crossings there were sixteen frogs, four special, open hearth, cast-steel, double switches and mates, four single switches and mates, four 90-deg. angle crossings and six 38-deg. angle crossings. All were made from 9-in. Cambria guard rail of weight 104 lbs. and 107 lbs. per yard.

The Johnson "built up," "cast-steel" and "guarantee" work is also used extensively in Chicago, while the Chicago City Railway Company uses the hardened center frogs, mates, switches, etc., of the Pennsylvania Steel Company in building its own crossings and other important special work.

In Fig. 36 is shown a cable curve and trolley crossing recently put in by the Chicago City Railway Company at Twenty-second Street, Indiana Avenue and Cottage Grove Avenue, and it may be interesting to speak of the way in which the old, worn-out crossing was taken out and the new one put in, as illustrating the rapidity with which such work can be done.

The new construction of the inside curve was put in position on the night of July 18, and that of the outside on the night of the 26th of July. The paving and concrete had previously been removed, the track and slot rails cut, bolts loosened and everything made ready. The old construction of one track was removed and the new section, together with the cable pulleys, was put in ready for the operation of the cars, after the cable stopped running at 1 o'clock, and the line was ready for service at 5 o'clock in the morning—this without even interrupting the running of the night horse cars. About fifty men with three overseers were required to do the work, the scene being lighted up by the ordinary torches employed for night work, and by special electric lights suspended on poles from the trolley wire, and lighted from the trolley circuit. Each curve with its portion of the crossings had previously been set up complete, in the rail yard of the company, and each man had been given instructions as to how he should perform his part of the labor when the section was to be put in place, so that by this drill the installation was effected in an incredibly short time, as noted above.

This curve is of about 80-ft. radius, and extends about 50 ft. on Twenty-second Street, and about the same distance on Cottage Grove Avenue. In the new construction cast yokes were employed in place of the wrought iron yokes of the old construction. A 7-in. rail was employed, with $7\frac{3}{4}$-in. guard rails. This curve was constructed by the Falk Manufacturing Company, of Milwaukee, and was installed by Assistant Superintendent Heidelberg and Track Master Stephens, of the Chicago City Company.

The practice is becoming quite general in Chicago of omitting copper bonds where cast welded joints are made, it being held that the close union of metals brought about by pouring the molten iron around the rail sections in the process of cast welding, forms an electrical connection of greater conductivity than the rail itself, which is, of course, all that can be desired. In order to promote this union great care is taken by all the companies when welding the rails to clean the ends thoroughly by a sand blast. Cross bonds are, however, used every 500 ft. in order to unite in parallel the conductivity of the two rails. With ordinary fish-plate joints, however, of which there are still a great many in Chicago, the usual copper bonds, of practically all existing types, are employed.

FIG. 31.--CAST WELD JOINT MOLDS—MISCELLANEOUS SECTIONS

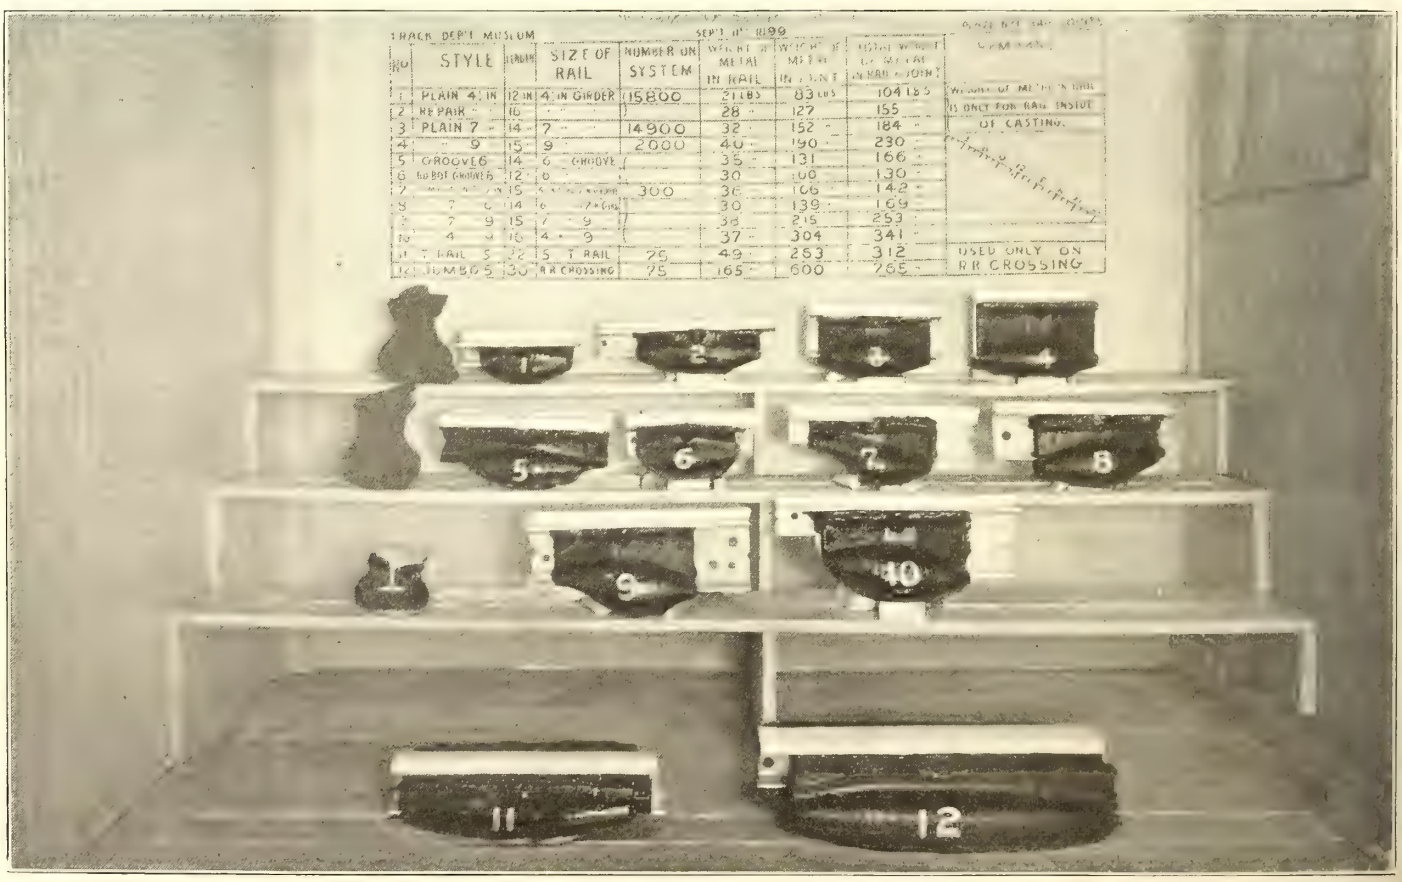

FIG. 32.—CAST WELD JOINT MOLDS—MISCELLANEOUS SECTIONS

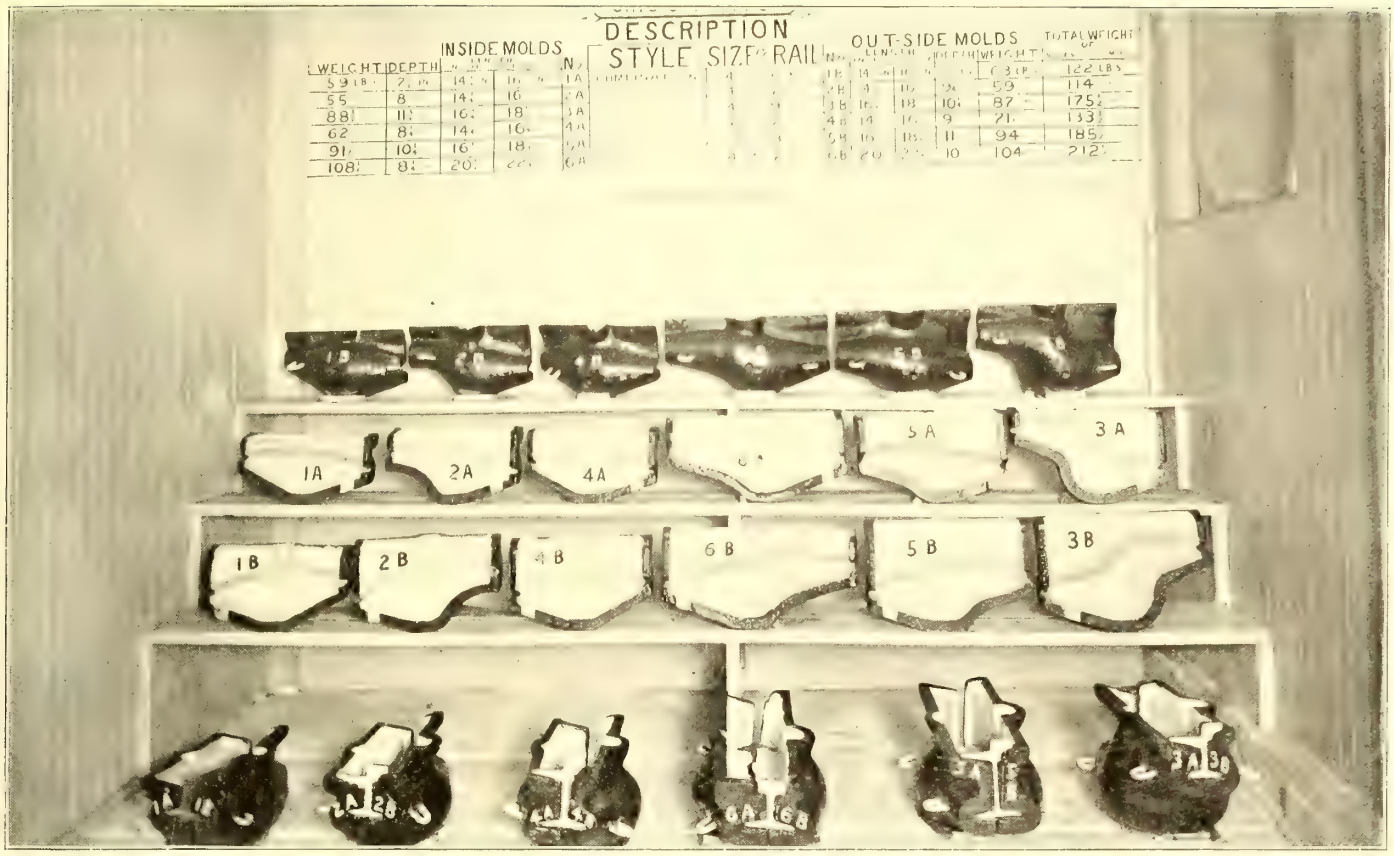

FIG. 33.—CAST WELD COMBINATION JOINT MOLDS

FIG. 34.—CAST WELD RAILROAD CROSSING JOINT MOLDS

The rails of some of the elevated lines are bonded in three ways. At the joints of the third-rail conductor two 0000 Crown bonds are used with stranded wire. This is figured to have about the same carrying capacity as the 45-lb. conductor rail. On the track rails, four, six or eight copper leaf bonds are used, of 350,000 c.m. capacity, and with sweated copper riveted terminals. The entire structure is used as a return and is bonded to the track rails by copper lugs for which a No. 00 stranded copper wire is employed, this wire being 22 ins. long and coiled around three times to take up any vibration.

FIG. 36.—CHICAGO CABLE CROSSING

ELEVATED RAILWAY CONSTRUCTION IN CHICAGO

The new Northwestern Elevated Railway, built from the beginning with the intention of using electricity as a motive power, is now approaching completion, and it is expected that it will be in operation by April 1, 1900. It is a two-track structure for the first two miles, and a four-track structure for the remaining five, the intention being that the two inside tracks shall be used for express service, and the two outside for local. The road is thus 7 miles long, with 25 miles of track, including that in terminal yards, and is built on private right of way for most of the distance. At the city end it has a connection with the Union Loop, around which its cars will pass on the outside track, also used by the Lake Street Elevated Railway.

There will be about three stations to the mile, at which the local trains will all stop, and will make an average speed of 14 miles an hour, but the express trains will stop only at every third station, and will make an average speed of 30 miles an hour, with only about twelve seconds dead time for each stop.

All the stations except two are located beneath the structure, and one agent will sell tickets for the four lines. At the express stations the structure swells out to provide for the necessary passenger platforms.

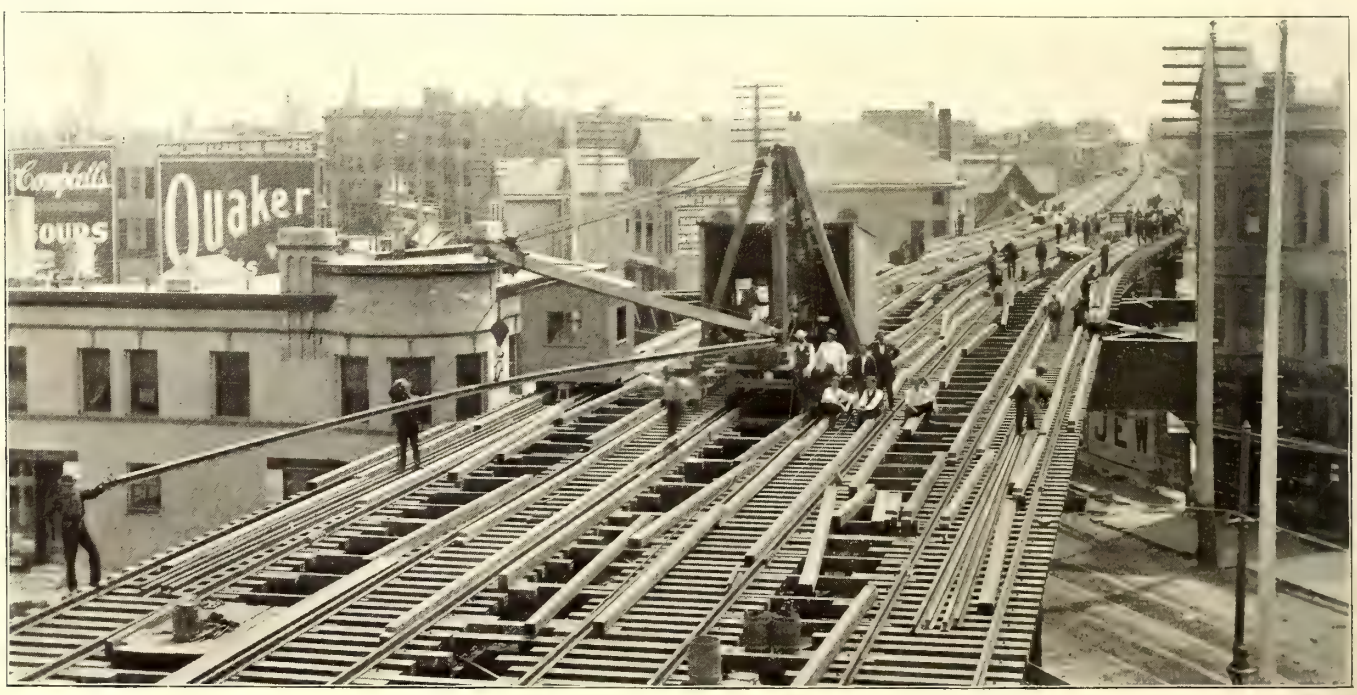

FIG. 37.—LAYING 60-FT. RAILS ON NORTHWESTERN ELEVATED RAILWAY

The supporting structure is mostly of the plate girder

type, but every 200 ft. comes a brace bent, shown in Fig. 45, by which the structure is thoroughly braced, and anchored to the ground, so as to prevent oscillation.

In the process of erecting the structure the braces and unions are riveted by means of pneumatic tools designed by the Chicago Pneumatic Tool Company. For operating the riveters gasoline engines are provided, which drive the compressors, the latter being of the Fairbanks & Morse style. The yokes of the large riveters have a throat of 50 ins., and are made of $4\frac{1}{2}$-in. iron pipe. These are supported by a jib from the car which carries the engine and compressor, as shown in Fig. 39. A pressure of a hundred pounds is generated, and large riveters are capable of heading a bolt from $\frac{7}{8}$ in. up to 1 in. in diameter. The hand pneumatic riveters are provided for the smaller bolts. Compressed air is also provided for the heating forges.

FIG. 38.—SETTING THE RIVETS

FIG. 39.—PNEUMATIC RIVETING

FIG. 40.—REMOVING RUST FROM STRUCTURE

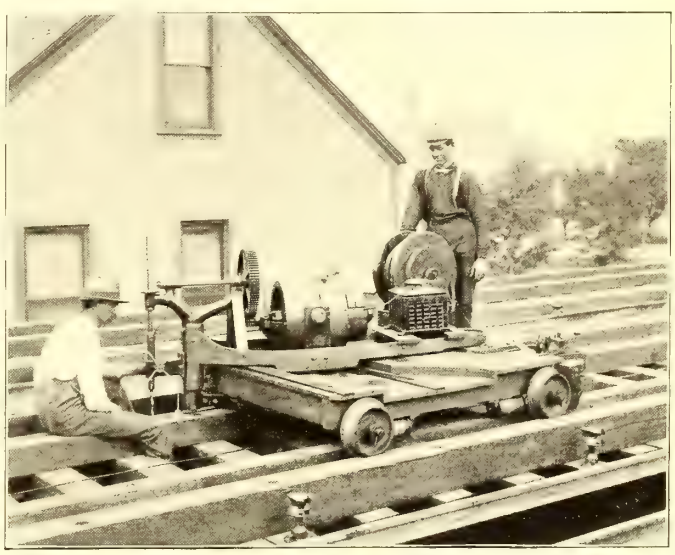

FIG. 41.—DRILLING HOLES FOR BONDS

An interesting feature in connection with the erection of this structure is the method employed for removing the rust from the girders, braces and posts, after being erected. As much of the material had lain for three years on the ground before it was erected, it was naturally well coated with rust, so that it became necessary to remove this before the paint was applied. This work was delegated to C. R. Frederick, formerly superintendent of the Cicero & Proviso Electric Railway, of Chicago, and to accomplish the work, Mr. Frederick devised a system of wire brushes, operated by electric motors. These are shown in Fig. 41. For this purpose three 12-h.p. General Electric motors were secured, and these were mounted on small cars or trucks, which are readily moved along by hand, on top of the girders, as shown. Three of these motors were mounted on each track, and to facilitate the work scaffolding is erected, which is supported by hooks suspended from the structure. The brushes are circular, about 8 ins. in diameter, and 5 ins. deep, and are constructed from No. 18 steel broom wire, which is prevented from spreading too far by an iron band shown in the illustration. The brushes are driven from the motor by means of flexible shafts, manufactured by the Chicago Flexible Shaft Company, and revolve at a speed of 1800 r.p.m. As the brushes revolve the wires bend out against the ring, so they are all brought close together for effective work. These brushes last about two days, and are made by the company's employees. By means of these appliances the gang of men employed is able to clean about eight spans of the structure, or more than 300 ft. a day. For reaching corners and angles that are inaccessible with the brushes, specially designed chisels and wire hand brushes are employed. The

motors are operated from the neighboring trolley circuits by means of feeders laid along the elevated structure.

As fast as the members are cleaned of rust two coats of paint are applied, the first being of a brown color, and the second of graphite paint, composed of 20 per cent of oil,

FIG. 42.—A CURVE ON NORTHWESTERN ELEVATED RAILWAY

40 per cent of graphite and 40 per cent of oxide of iron. This material is furnished by Heath & Milligan, of Chicago.

Another interesting appliance in connection with the equipment of the structure, is an electric drill and reamer, shown in Fig. 41, which is employed for drilling the bond holes in the rails, and in the flanges of the plate girders, to provide for the bonding, the rails being connected with the structure for the return circuit.

The work of track laying in the completed structure is being performed by the North American Construction Company, and in Fig. 38 is shown one of their gangs at work, and also some of their self-propelled steam derricks, by means of which 60-ft. 80-lb. rails are lifted from the street and laid in position on the structure. The work of laying the four tracks goes on at one and the same time. The derrick is mounted on a track which travels on the inside rails of the steel tracks, and is propelled by a capstan, an anchor rope being first thrown out. At the side of the derrick is a portable cabin, in which the supervising engineer has his office, which thus moves along the structure as the work progresses.

The rails are of the 80-lb. American Society section, shown in Fig. 46, and are joined by the Weber joint, which has been so successful on the Manhattan Elevated Railway in New York. Between the joints the rails rest on Serviss tie plates. The special work for the terminal yard, Fig. 30, page 311, is not yet let, but the Paige Iron Works Company, of Chicago, has the contract for all the special work south of the yards. Forty-five-pound conductor rail will be laid by the company's engineers.

The first equipment of rolling stock for this line will consist of twenty-seven motor cars, with two motors each, and ten cars with four motors each, the latter designed for express service. All are built by the Pullman Palace Car Company. The standard motors are G. E. No. 55, rated at 150 h.p. each. The four motor equipments will be geared for high speed. The motors will each haul two trail cars, and the trailers, as well as the motors, are vestibuled. For regular service a maximum speed of thirty-three miles an hour will be reached, with a 600-volt current at the motor terminals. As before stated, express trains will average 30 miles an hour, and local trains 14 miles.

The car bodies, shown in Fig. 44 are 6 ft. wide, with a 40-ft. body length and 47 ft. over all. The motor cars are provided with two cabs, which are located on the left-hand side, as all trains will be run left-handed on account of the Union loop terminus. One cab is built larger than the other in order to provide for the housing of the motor air-compressor for the braking system. This compressor is of the Christensen type, as is also the engineer's con-

FIG. 43.—GENERAL VIEW NORTHWESTERN ELEVATED STRUCTURE

trolling valve, while the brakes themselves are Westinghouse.

In the construction of the motor cars the frame work of the floor is composed of steel beams, reinforced with oak and yellow pine timbers. The corner posts are also of steel of riveted truss construction. The deck framing is

of unusually heavy timber, as are also the braces and structural features of every part.

A complete motor car, including the trucks and motors, will weigh 55,000 lbs., while the trailers weigh 32,000 lbs. The floors are double, with a layer of builders' felt, $\frac{1}{8}$-in. thick, between. The windows are unusually large, and glazed with heavy plate glass. The doors, which are on the sides of the vestibule, take the place of gates, and are designed to be opened and closed by means of a hand lever, with a check closing arrangement. The interior finish of both motor and trail cars is in quartered oak, with ceilings of the same material, the latter being trimmed in delicate figures of aluminum leaf. The deck lights are designed to be operated by a single lever. The seats are rattan, of the Hale & Kilburn manufacture. The motor cars have side seats only, while the trail cars have a combination of side and cross seats, after the regulation New York style. The cars are equipped with Van Dorn couplers, the standard of all the elevated railways of Chicago, and are lighted by means of a row of electric lamps on each side of the deck. The outside color is of the Pullman standard, with gold trimmings and lettering.

FIG. 44.—STANDARD CAR, NORTHWESTERN ELEVATED RAILWAY

The cars are all mounted on Hedley trucks, manufactured by the McGuire Manufacturing Company, of Chicago.

The structure itself was built after designs made by C. V. Weston, the company's chief engineer, and is being erected under his supervision. The third-rail equipment, the bonding, and, in fact, all of the electrical portion of the installation has been in charge of James R. Chapman, the company's chief electrical engineer, who has also designed the power station, which was described in the STREET RAILWAY JOURNAL for July, page 454.

For valuable information and assistance in the preparation of this paper the STREET RAILWAY JOURNAL is indebted to practically all the officers of the Chicago surface and elevated railways, and particularly to D. G. Hamilton, president, George O. Nagle, assistant general manager, and G. W. Knox, electrical engineer, of the Chicago City Railway Company; John M. Roach, general manager of the Union Traction Company; James R. Chapman, electrical engineer of the Chicago Union Traction Company and of the Lake Street and Northwestern Elevated Railway Companies; F. L. Fuller, superintendent of the West Chicago Street Railroad Company; H. M. Sloan, general manager of the Calumet Electric Street Railway Company; C. V. Weston, chief engineer of the Lake Street and Northwestern Elevated Railway Companies; Marcellus Hopkins, general manager, and Sargent & Lundy, consulting engineers, South Side Elevated Railroad Company.

THREE ESSENTIALS IN SUCCESSFUL STREET RAILWAY MANAGEMENT

The valuable suggestions regarding the management of street railway employees and their relations with the public, contained in the following letter, are worthy of most careful attention by street railway managers:

CHICAGO UNION TRACTION COMPANY,
Office of the General Manager,
CHICAGO, Sept. 23, 1899.

EDITORS STREET RAILWAY JOURNAL:

On many occasions I have been solicited by you to give a chapter from my experience, on the practical operation and management of street railways, for the STREET RAILWAY JOURNAL; and I have as often declined, but upon mature deliberation, I am of the opinion that if street railway managers would more freely give the result of their experience, on the important features of the management of great street railway corporations, through the columns of your paper, it would result in great good to the fraternity at large, for I consider the STREET RAILWAY JOURNAL one of the best mediums for distributing the experience of those who are competent to speak upon the various important lines on which employees should be especially educated and trained.

There are three great and important features in the management of street railways, these are: The Lessening of Accidents; Economical Use of Power by the Motorman; Politeness and Attentiveness of the Conductors and other Employees to the Patrons and Public.

I will not attempt at this time to discuss fully the manner in which it is possible to so train employees that accidents will be almost or entirely obviated, thereby saving to the company large sums of money which are now paid out and which are of no particular good to the parties who receive it, while accidents result in a great sacrifice on the part of the employees and their families, from time lost by suspension as a means of discipline, and frequently in loss of position by employees.

A motorman or gripman can doubtless be so trained that he will keep his mind upon all of the possible conditions that may arise in the street upon which he is traveling, so that the carelessness of others can be counteracted by his extraordinary good care and caution, thereby preventing accident. If he will constantly keep a close lookout and refuse to converse with passengers or other employees or refuse to allow his attention to be called to any direction other than the line of duty, he will give an ideal service. The best evidence that this can be done is that we have men in our employ who have not been relieved from duty on account of accident for fifteen years, showing that most accidents are brought about by gross carelessness.

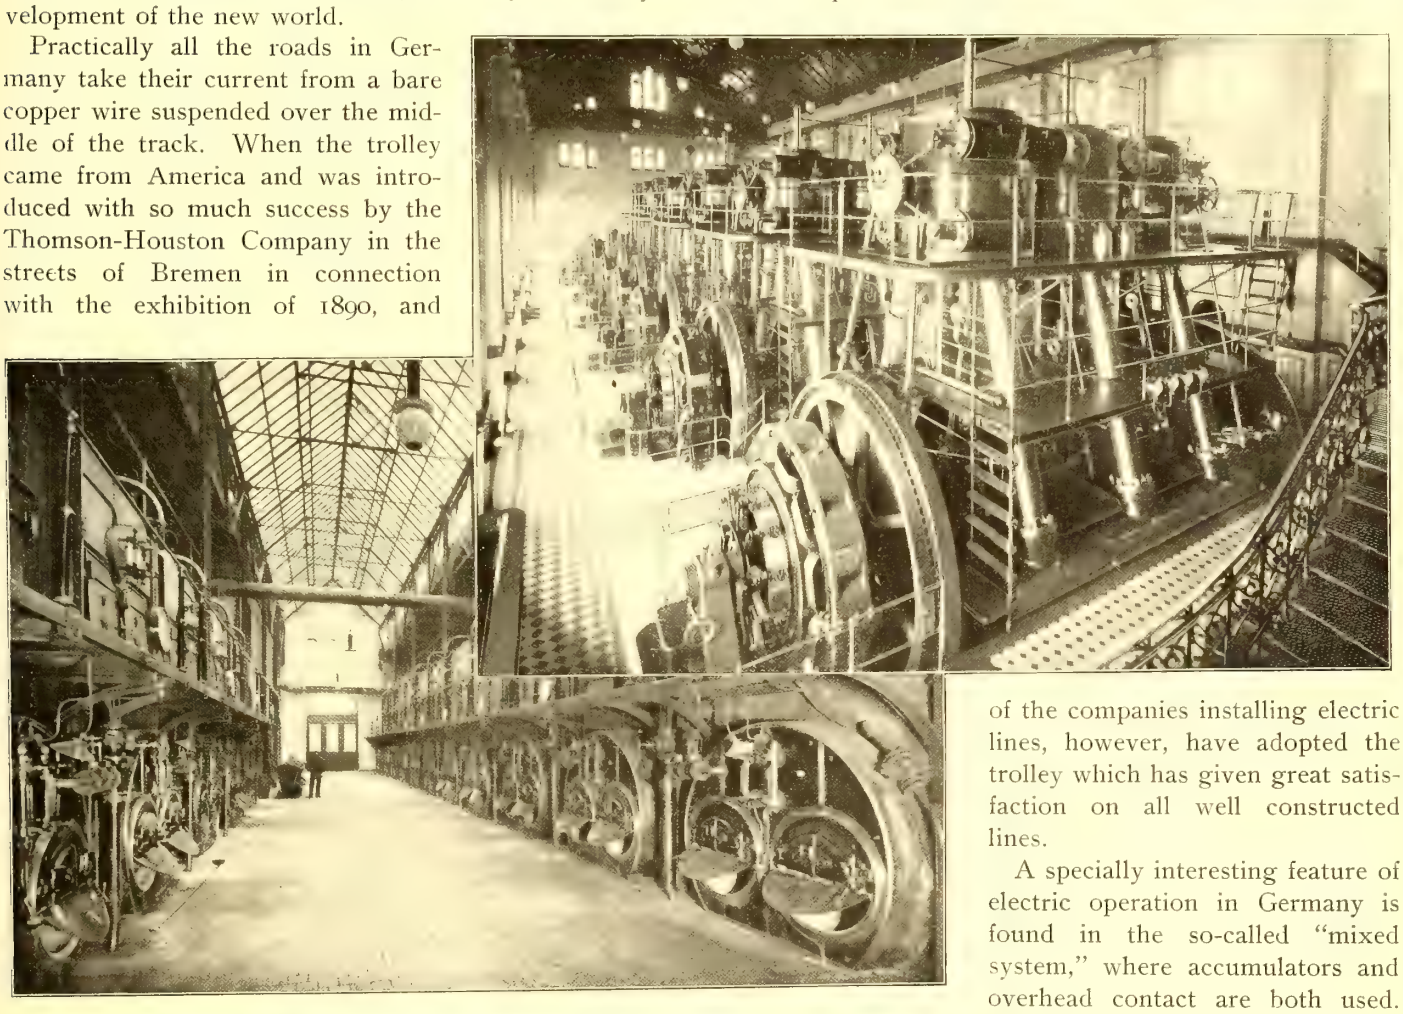
In case the conductor is taught to properly attend to his duty, and to see that each person is entirely on or off the car, as the case may be, especially in the case of aged persons, before he gives the signal for starting, it is possible for him to operate his car for a number of years without being disciplined by suspension and consequent loss of time. He will thus save to the company, by whom he is employed, a large amount of money which in no way contributes for the comfort of the public or employees.

Again, a motorman by the economical use of power in manipulating the controller could save enough to the company so that the management could afford to increase his wages from 25 per cent to 60 per cent a day without losing any more money than they do by the crude and unscientific manner in which he operates his car. If motormen would learn to keep a close lookout for teams and for crossings, and instead of keeping their power on until they are forced to make an emergency stop by cutting the power out quickly and applying the brakes with force (thereby wearing the brake shoes and all the brake mechanism from the handle to the wheel) he would coast along the street where danger is anticipated, and thereby save the current and his own physical power and consequent wear and tear upon the rolling stock, he would save enough to add another per cent to his wages. In the same connection very much can be saved in the wear of the special work at crossings by passing over these sections at a moderate speed, not only preventing accident, but relieving the hammer blow that the wheels deliver at each crossing point of the structure. If all these amounts were added together, including the flatting of wheels and the cost of investigation and suspension, all of which are due to carelessness, either by the motormen or by the drivers of vehicles on the street, an enormous sum could be accumulated in ten years that could be divided between the employees and the company to their mutual advantage.

No one knows better than I the many trying ordeals with which street railway employees have to contend, and no one more fully appreciates the situation, but while riding upon the cars of our own company, as well as on the cars of other companies, I am free to confess that employees do not, as a general thing, conduct their business with the care they should exercise in order to be of the greatest service to themselves and their employer.

I am aware that in some cities there are fewer accidents than in others on account of local conditions, and the manner in which the Police Department conducts its part of the business. In Chicago the conditions are particularly trying, and it is hard to prevent accidents when these are taken into consideration. Compared with Boston, Philadelphia and other large cities where the streets are properly paved, and crossings carefully guarded by policemen who have power to compel the public to obey their signals, Chicago is at a disadvantage, but notwithstanding these considerations as noted above, a certain class of employees never have accidents, so it is doubtless possible to so train men or to get such a class of men that accidents will be entirely obviated.

I suggest the above for the special consideration of employees, and others interested, and hope that they will be able to so train themselves that they will have the advantage of the vast sums now wasted. Very truly yours,



J. M. ROACH.

ELECTRIC RAILWAY PRACTICE IN GERMANY

BY LOUIS J. MAGEE

There is no very important town in Germany to-day where electric cars are not in operation or definitely provided for. The historical road between Frankfort and Offenbach, with its two split iron pipes as overhead conductors was put in operation in the year 1884, long before the trolley boom in America, and has remained unaltered throughout the changes which electric traction has experienced in going from its home in Germany, till the coming back, with the new impulse given it by the trolley development of the new world.

Practically all the roads in Germany take their current from a bare copper wire suspended over the middle of the track. When the trolley came from America and was introduced with so much success by the Thomson-Houston Company in the streets of Bremen in connection with the exhibition of 1890, and by the Allgemeine Elektricitäts-Gesellschaft, who started their road in Halle, in May, 1891, the upward pressure contact system, despite the æsthetic consideration of a people who keep their streets orderly and clean, met with general approval as simple and practical. Siemens & Halske, however, true to the traditions of a firm which laid the very foundations of the electrical industry half a century ago, refused to stake its ancient reputation on the vagaries of the trolley-wheel, and started out on the modern phase of its career in street railway work with its broad bow or stirrup contact piece. This was first installed on the equally historical Siemens' road in Lichterfelde, where, since 1881, current had been sent out through one rail of a track laid on wooden sleepers, and returned to the station through the other. This stirrup method of a moving contact piece, which causes no difficulty with jumping the wire, and does not require the contact wire to conform so closely to the line of the track, is still to-day the standard used by Siemens & Halske in the many roads they have built. The bow, or "Bügel," as it is called in German, is about 5 ft. wide at the top, and has inlaid at that part where it can come in contact with the wire, a strip of aluminum containing, in a groove, lubricating material. This strip of soft metal is renewed from time to time. Most of the companies installing electric lines, however, have adopted the trolley which has given great satisfaction on all well constructed lines.

INTERIOR ENGINE AND BOILER ROOMS, HAMBURG POWER STATION

A specially interesting feature of electric operation in Germany is found in the so-called "mixed system," where accumulators and overhead contact are both used. The batteries are not moved from the car for charging, but receive their charging current while the car is on a part of the line provided with overhead construction, as, for instance, in the less thickly settled districts of a city. As soon as the car comes to the zone, within which no trolley wires are allowed, the contact bar, or trolley pole, is laid down on the roof of the car, and the inner portion of the city is traversed by means of the current from the batteries alone. This system is in use on a large scale in Hanover, Dresden and Berlin, and also in Hagen in Westphalia. Its introduction has brought with it, naturally, the development of a more complicated controller, and the cars and trucks are heavier than would otherwise be the case. Despite first cost and maintenance of accumulators, and the careful attention which they require, it can be said that accumulators used in this way, although much dearer than

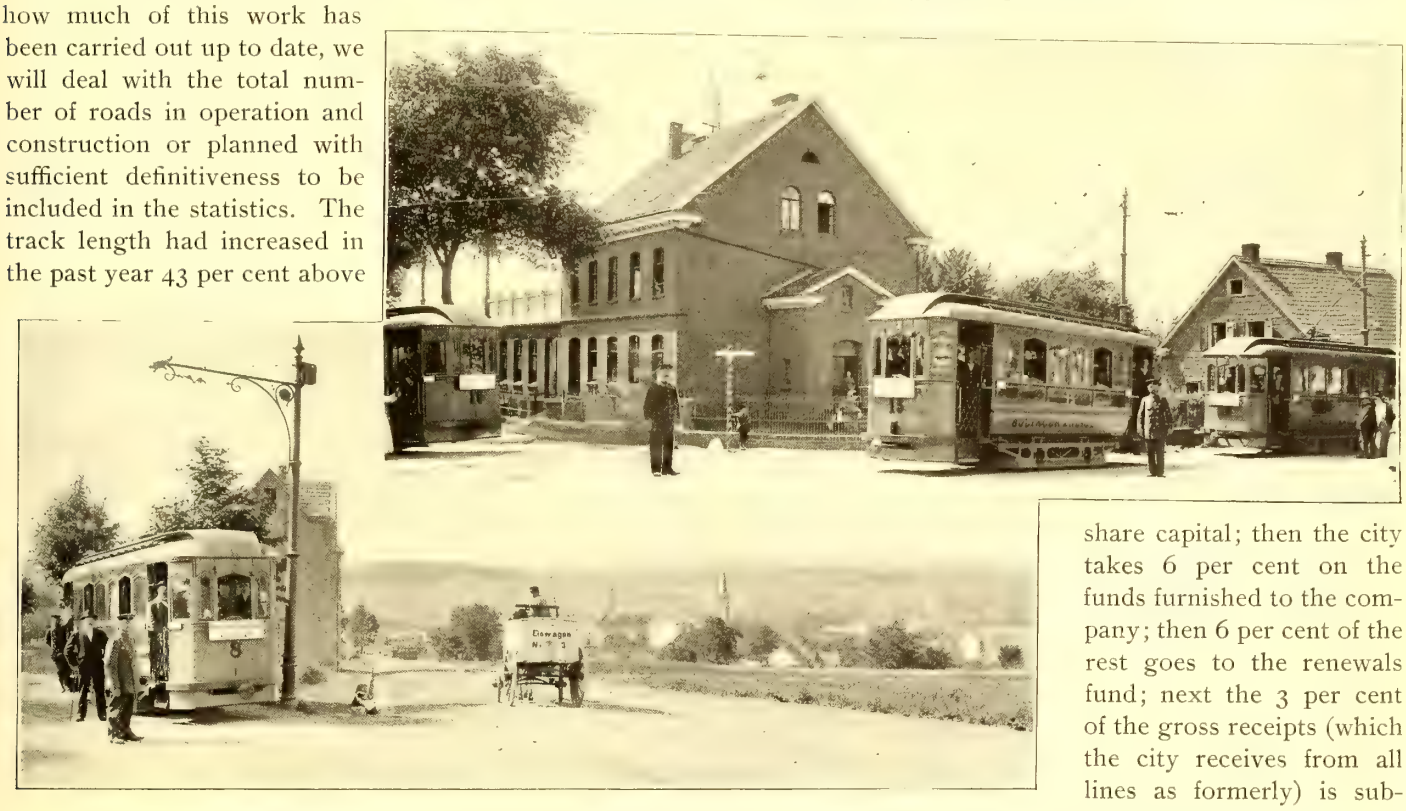
simple trolley lines, are sufficiently reliable and economical to bring about paying operation. In the cities where batteries have been introduced, the trolley was not permitted in all the streets; the great number of switches and crossings would have made the operation of a conduit rather complicated, and it was simply a question of the accumulator "mixed system" or horses. Possibly some good closed conduit system may eventually take the place of the accumulators on the comparatively short city lines for which they are required to-day, and the trolley may be allowed to encroach a little further in those streets where it is now forbidden.

BRACKET POLES IN BERLIN

SPAN WIRE CONSTRUCTION IN POSEN

As to Berlin, it would be giving a false impression to say that the accumulators are used for the more closely settled districts of the cities, for, as a matter of fact, the trolley runs through narrow and busy streets, but the distinction is made more especially with reference to a few of the finer streets containing the better shops. In Berlin battery cars have been running on this system since March, 1898. There are now 200 large accumulator cars in operation, and thirty small accumulator cars, and they are constantly increasing in number. The large cars for forty passengers weigh about 16 tons and the battery weighs about 2.5 tons. The latter is made up of 200 cells and has a total capacity of about 30 amp. hours with an average run of 2 miles. The small accumulator cars have batteries of 1.9 tons, with about 23 amp. hours capacity, while the longest course made regularly by one of these cars is 3 miles, going into the accumulator zone and returning to the trolley wire. The battery gets its charge again on about $1\frac{1}{2}$ miles of the trolley line. In most cases, however, the accumulator car runs right through the city so that it gets a charge from the trolley lines on both sides of the accumulator zone. An amusing incident once took place with this system. While an accumulator car was running on the trolley line, the central station met with an accident and the supply of current ceased. The car kept on undaunted, however, being quite independent of the source of supply.

ELECTRIC CARS IN MUNICH



These accumulator cars have, of course, sufficient capacity not only to cover the average distance mentioned, but to do it with all conditions of track and with tow-cars.

On this road in Berlin, and on roads in several small towns, accumulator traction, pure and simple, is carried out, but results as far as known do not recommend this practice for very widespread adoption. There is an interesting case in Frankfort which may be considered to be half way between the "mixed system" mentioned, and out and out accumulator traction. On a line 1 mile long, four cars are running, each equipped with a 2-ton battery of eighty-four cells of the Pollak type. After making its journey over this line and back, the car stands on an average six minutes at a charging mast and then repeats the trip. The average charging current is 60 amps. at 210 volts. In this case, therefore, instead of getting its charge during the longer time while traversing a line provided with a trolley, it accomplishes the same work in a very much shorter time, and at one single point.

In Munich, six accumulator locomotives are to be used

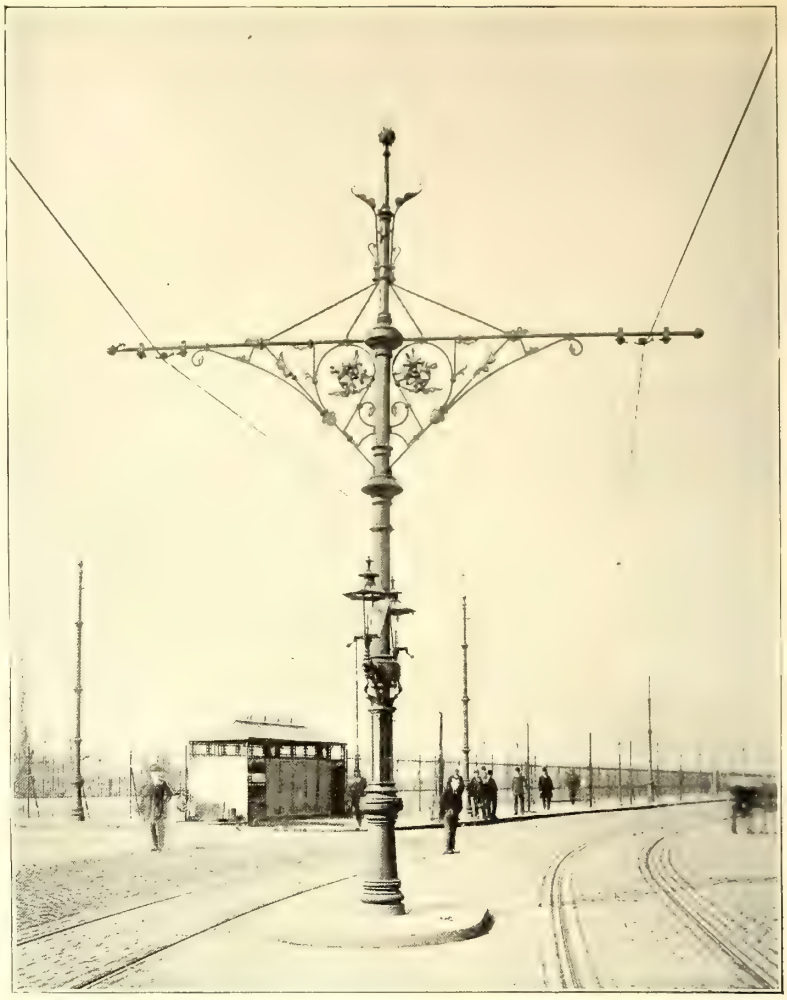
over about 500 yards of line to draw the trolley cars. The locomotives will be charged at fixed points on the track. This experiment will be interesting as showing whether the complications in service, delay, and other objections urged against such a system outbalance the disadvantages of the "mixed" accumulator system or conduits, for short stretches where trolley is forbidden.

At the beginning of this year there were electric roads in seventy-seven principal towns in the German Empire. In addition to these, however, there were many surrounding towns connected by roads running from the principal towns. In these cities electric operation covered about 1313 miles of track, with about 3500 motor cars. Adding the roads which were at that time building or definitely laid out and contracted for, the number of towns or groups of towns increased to 103, and the length of track to 2047 miles,* or of line, 1575 miles. Without trying to determine how much of this work has been carried out up to date, we will deal with the total number of roads in operation and construction or planned with sufficient definitiveness to be included in the statistics. The track length had increased in the past year 43 per cent above the previous year, and the number of motor cars 41½ per cent. As to the more important cities to-day very complete and extensive electric lines exist in Aix-la-Chapelle (Brunswick), Chemnitz, Dresden, Hamburg, Hanover, Leipzig, Munich, Stuttgart; while Breslau, Kassel, Frankfort, Cologne, Magdeburg, Königsberg and Düsseldorf are building, or about to begin. Berlin was late in adopting electric traction, but has been rapidly making up for lost time, having about 550 motor cars in operation at the present date. The Hamburg lines, which were started up in 1894, represent about the best electric road to be seen in Germany in the way of an extensive network well equipped and splendidly managed.

SCENES ON ELECTRIC SUBURBAN RAILWAY, SOLINGEN

There are long lines of interurban roads in operation and under construction in the more important industrial districts of Silesia and the Rhine. There are sixteen roads, with about 10 per cent of the total mileage, which are not in the hands of private capital. Two of these are the property of the Crown, and the other fourteen, with about 8 per cent of the total mileage, are the property of towns or groups of several communes, as, for instance, in Düsseldorf, Barmen, Elberfeld, and a number of towns in that busy district, Frankfort-on-the-Main, and Königsberg. Even in the few cases where towns own the property there is a tendency to let out the operation to private contractors for a long term of years. In Munich the city participates in the ownership of the road, but it is operated entirely by the company. The Munich Company, with M.6,000,000 shares and bond capital, built and owns and operates the horse lines; but instead of lengthening its concession, which runs only till 1907, the city made an arrangement by which it acts as a silent partner with the company. The company thereupon introduced electric traction with the city's money on the following basis: The city guarantees the company M.930,000 per annum to cover interest on its share capital; then the city takes 6 per cent on the funds furnished to the company; then 6 per cent of the rest goes to the renewals fund; next the 3 per cent of the gross receipts (which the city receives from all lines as formerly) is subtracted, and what is left goes, three-quarters to the city and one-quarter to the company. This final quarter amounts to about M. 100,000. The Munich Company has 100 electric cars and fifty-five horse cars, which latter will disappear this year.

As to the question of capital interested in the other 90 per cent of the roads (always reckoning by mileage) it would, perhaps, be fair to say that about 20 per cent to 25 per cent of the work was done on orders given independently to electric companies by existing horse roads, in which cases, however, the electric companies entered into heavy guarantees as to the economical operation. Several unsuccessful experiences with accumulators before the days of the trolley had made many European street railway managers very distrustful as to electric traction, and they figured very carefully before making the extensive changes accompanying it.



Twenty per cent to 25 per cent more represents existing horse roads bought up, or at least strengthened by capital connected with the electric groups. The remaining 40 per

*Elektrotechnische Zeitschrift, Jan. 5, 1899.

cent to 50 per cent represent comparatively new roads owing their existence almost entirely to the activity of the electric companies. They are owned by the electric companies or their financial backers, or by companies promoted by the latter. In several cases the electric companies have formed special companies for taking over and operating electric roads so as to divide the expenses of expert central management among several smaller roads.

It should be remembered that figures as to electric roads or lighting and power plants geographically confined to the German Empire give no idea of the work done by German firms. They have their agencies and branches all over the world and have cultivated export business. German electric firms have built or are building roads in Cairo, Batavia, Budapest, Vienna, Bucharest, Brünn, Olmütz, Aussig, Prague, Brussels, Liège, Toulon, Bergen, Christiania, Copenhagen, Genoa, Naples, Turin, Florence, Palermo, Leghorn, Kiew, Riga, Lodz, Bilboa, Basel, Seville, Barcelona, Santiago (Chile), Bahia, Para, etc. The roads installed within the borders of the Empire represent, therefore, the technical methods employed in very many lands far distant therefrom.

As has been frequently told in the Street Railway Journal, most of the German banks invest largely in the industries and electrical enterprises, and follow up these investments very closely. Each of the large electric companies has its group of bankers interested in its own direct manufacturing activity and in the enterprises promoted by it for the introduction and use of electric

MODERN CONSTRUCTION—DOUBLE BRACKET POLE IN HAMBURG

EARLY CONSTRUCTION—TUBULAR CONDUCTORS ON THE FRANKFORT-OFFENBACH ELECTRIC RAILWAY, THE FIRST COMMERCIAL RAILWAY IN THE WORLD

apparatus. It is naturally difficult to interest local capital in lighting, power and railway enterprises excepting in the large cities. The electric companies, therefore, make the necessary financial examination and technical studies, and recommend these enterprises to their banks. This led naturally to the permanent union of various groups of banks in the formation of large financial companies for furnishing the capital for electrical enterprises. These companies take responsibilities and furnish sums beyond the power of the electrical manufacturing companies, and at the same time make a large proportion of their profit in working up enterprises into such a condition that they can be presented to the public, and in the reorganization of old companies. If the *haute finance* of Germany has indirectly profited in a vast scale from the development of the electrical industries during the last six or eight years, the electrical industdustries must, on the other hand, admit that the orders would not have been forthcoming without the aid of their financial friends. This applies to the electric roads especially.

The more important financial groups are as follows:

Companies and Groups.	Share Capital	Bonds	Last Dividend
Siemens & Halske, of Berlin	40,000,000	20,000,000	10 p. c.
Electric Light & Power Company, Berlin	30,000,000	...	..
Schuckert & Company, Nuremburg	28,000,000	16,000,000	14 "

Companies and Groups	Share Capital	Bonds	Last Dividend
Continental Company for Electrical Undertakings, Nuremburg	32,000,000	20,000,000	..
Electric Installation Company, Dresden	6,000,000	....	..
Allgemeine Elektricitäts-Gesellschaft, of Berlin	47,000,000	15,000,000	15 "
Bank of Electrical Undertakings, Zürich (owned by A. E. G.)	23,000,000	....	..
General Local & Street Railway Company, Berlin	25,000,000	....	..
Electrical Delivery Company, Berlin	6,000,000	....	..
Union Elektricitäts Gesellschaft, of Berlin	18,000,000	....	12 "
Company for Electrical Undertakings, Berlin	30,000,000	20,000,000	..
Helios Company, of Cologne, (which has recently absorbed the Felix Singer Company)	16,000,000	4,000,000	11 "
Company for Electric Plants, Cologne	16,000,000	....	..
O. L. Kummer & Company, of Dresden	7,500,000	500 000	10 "
Company for Electrical Plants and Roads, Dresden	2,000,000	....	..
Lahmeyer, of Frankfort	4,000,000	3,200,000	10 "
German Company for Electrical Undertakings	15,000,000	....	.. "

These are the chief groups interested in street railway work. Each group represents a finely equipped factory or several factories. The capital involved is about M. 480,000,000 or $114,000,000. Some thirty-eight banks and private banking houses are actively interested in these groups. The capital of these banks may be roughly estimated at M. 1,500,000,000 to M. 2,000,000,000, or about $400,000,000 to $500,000,000.

As to the earnings of the street railway companies it may be said in general that while they (like all share companies in Germany) have a laudable desire to create large reserve funds, and thus provide for unexpected renewals and changes in their mechanical outfit, they pay in dividends everything which they cannot satisfactorily prove to be necessary and reasonable in the direction of special and regular reserve funds. Naturally the share-holding public want as large a dividend as possible. Over-capitalization is not possible according to German practice or under the German laws. Trolley traction has, of course, proved cheaper than horse traction, and in several cases has actually brought moribund railways to life again and made them most valuable properties. In the case of some towns where it seemed hardly possible that a street railway could pay, electricity was installed with good financial results. Statistics as to the increase of traffic upon the introduction of electricity are difficult to establish in a fair way because the introduction of electricity not only brought much better accommodations, better cars, better lighting, fast service, the idea of novelty, etc., but also it is to be remembered that the larger towns of Germany are growing very rapidly, so that horse cars if retained would also have shown an increase. There is to be seen, however, all along the line an increase in car-miles run, the number of persons carried, and the receipts. The receipts per car-mile range

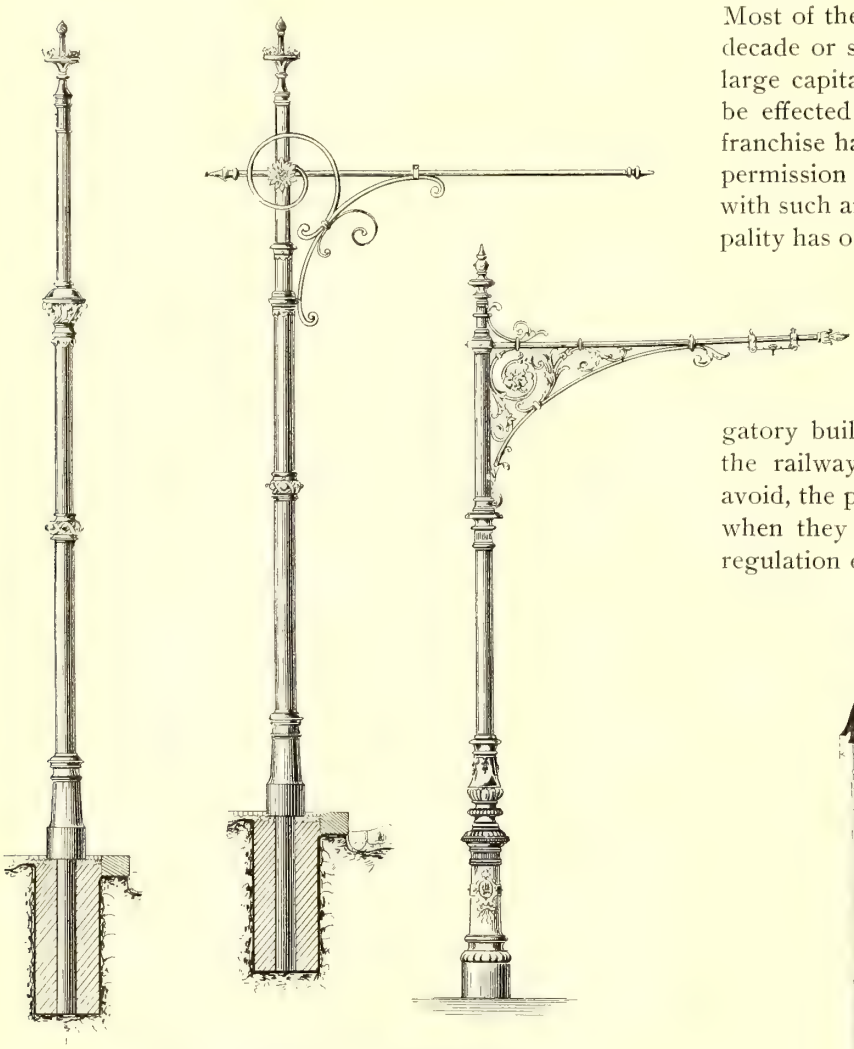
DIFFERENT TYPES OF OVERHEAD CONSTRUCTION

all the way between 11.5 cents and 19 cents, but average about 13 cents.

A splendid instance of the advantages of electric traction is to be seen in Remscheid, an industrial town near Solingen, and like Solingen a great producer of small steel ware.



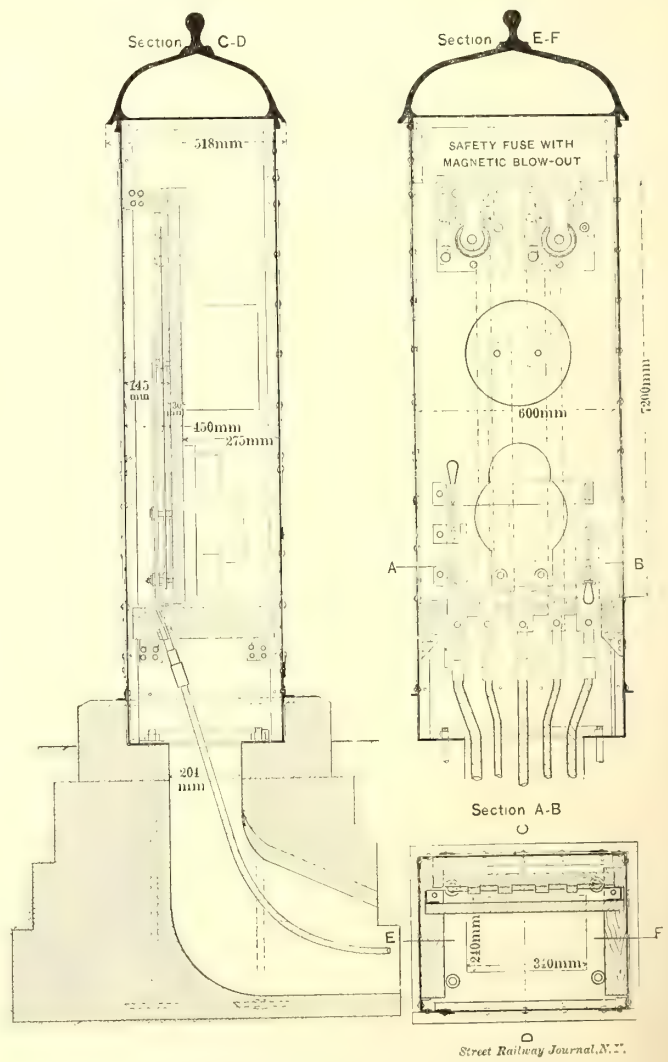


FIG. 1.—POLES IN COMMON USE

The town lies on a hill, and the maximum grade of 10.6 per cent was too much for any other street road traction system, so that this whole district in which the small artisans, working in their own homes, had to carry their baskets of half-finished wares to the larger factories, was entirely without any public transport system. It was one of the first towns to introduce electricity, and the receipts have increased nearly 10 per cent each year, being now over 16.8 cents per car-mile. Barmen-Elberfeld lines also serving a crowded and busy industrial district, show an increase of 44 per cent in the receipts of 1898 above 1896, when electric traction was introduced, that is for the three years 14.8 per cent per year increase. The average receipts in Dresden increased on the line of one company from 14.55 cents per car-mile in 1897, to 15.32 cents per car-mile in 1898. The other large company showed an increase at the same time of 12.25 cents to 13 cents, both companies being active in all improvements pertaining to electric traction and showing very efficient organization. In Leipzig the one large company increased its receipts 28.4 per cent in 1898 as against 1897, increasing at the same time in car kilometers run by 48 per cent. The other large Leipzig company has increased its receipts during the last three years, 14.3 per cent a year. These instances taken at random make a sufficiently good showing for electric traction.

The general franchise and permissions to build are granted by the local city and town authorities. In the case of new roads the franchise rarely exceeds fifty years. Most of the franchises of existing horse roads had only a decade or so more to run, and as the amortisation of the large capital necessary for electrical equipment could not be effected in this period, a material lengthening of the franchise has been granted in practically every case where permission for electrical equipment has been given. Along with such an extension of the railway franchise the municipality has often, though not always, laid down a large number of new conditions more or less burdensome to the companies, and leading generally to its participation in the receipts or profits of the railway company. Among these are included, for example, the obligatory building of lines in less populous districts which the railway companies would naturally be disposed to avoid, the purchasing of current from city lighting stations when they exist, the reduction of fares, the paving and regulation of certain streets, and minor advantages for the

FIGS. 2 AND 3.—SECTION SWITCH AND FEEDER BOX.

city or public, for which the making of a new contract of this character presents an opportunity.

The concession once granted, usually according to the

trolley system, it only remains to get the definite building permission after presenting the plans to the various local technical authorities. The street railway company or its contractors mark out the exact position of poles, feeders, new or altered tracks, etc., and the street engineers or the proper department of the police check up these plans to see if existing street arrangements, such as sewers, gas and water pipes, or prospective alterations in buildings or streets are interfered with. The government postal authorities are naturally consulted as to the effect on telephone and telegraph lines, and the necessary changes in telephone lines, and protecting of same by guard nets, etc., is adjusted, to be carried out by the Post at the expense of the tramway company. In putting through a new law which will grant them more power for long overland lines (right of expropriation, for instance), and relieve them from much petty bother with small communes and land-owners on cross-country routes, the postal authorities have shown great fairness toward the heavy current electricians, in that it is arranged that those who come into a street last shall stand the expense of alterations. An overland power transmission or interurban road can, in this case, keep its own way or in any case, will not have to move at its own expense in case it was there before the telephone or telegraph.

As above said, with the exception of the Post (and, of course, the Imperial railway authorities where crossings, etc., come into question, and the military authorities where fortifications are passed through or approached), the local authorities settle the matter, and no parliamentary act or imperial sanction is required. In case, however, the road runs through several communes and uses good turnpikes, provincial, county and district authorities come into play.

The following examples of franchises in the principal cities, dividends and participation of cities in profits may be of interest:

Street Railway Company	Concession runs until	Dividend	Participation of City in Proceeds
Great Berlin.....	1919	18%	8 per cent of gross receipts.
Berlin-Charlottenburg..	1937	5¾	
Hamburg.....	1922–1928	8%	25 per cent to 40 per cent of profits after 6 per cent dividend up to 10 per cent; over 10 per cent dividend 50 per cent of profits.
Great Leipzig.....	1935	8%	After three years 2 per cent of gross receipts, increasing with time to 5 per cent.
Munich.....	1907	10%	2 per cent to 3 per cent gross receipts.
Breslau.....	1922	8%	3 per cent to 5 per cent gross receipts according to scale of receipts.
German Street Railways, Dresden.....	1939	6%	.....
Dresden Street Railway	1921	8%	.....

In general, the government has a tendency to foster and

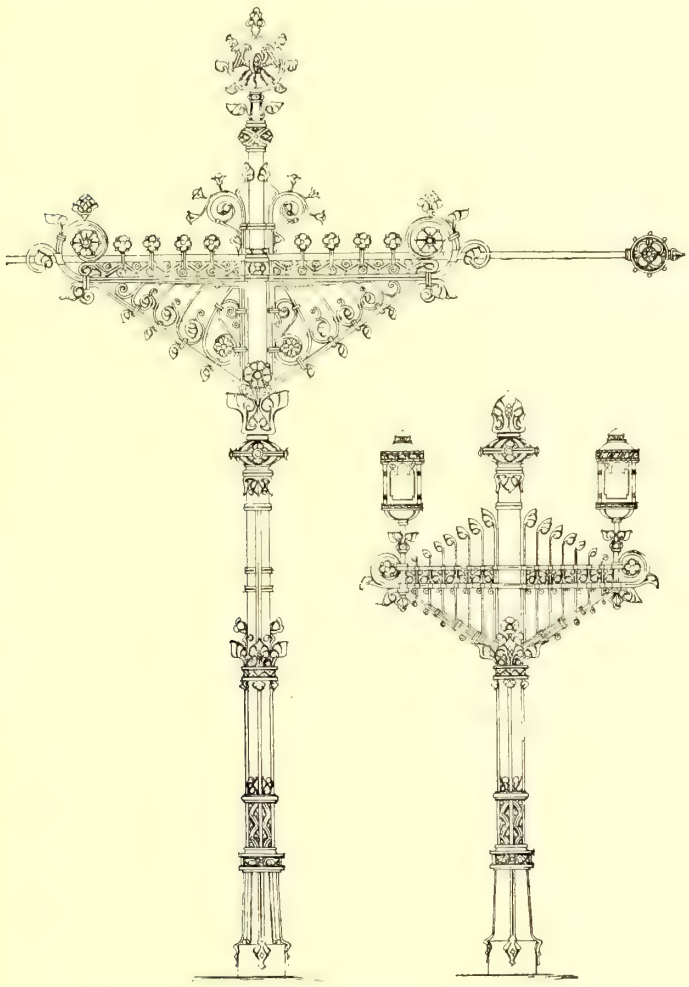

FIG. 4.—SPECIAL DOUBLE ARMS WITH LANTERNS TO BE INSTALLED NEAR THE EMPEROR WILLIAM CHURCH IN BERLIN

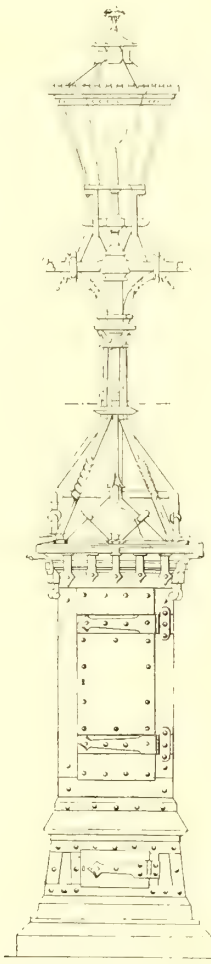

FIG. 5.—EXTERIOR OF LAMP POSTS IN HAMBURG WITH BOX FOR FEEDER SWITCHES AND METERS

aid undertakings of companies or private individuals whose end is to furnish light, power and better means of communication to a large number of communities, any one of which would in itself be too small to offer inducement for the investment of capital.

Street railways connecting several communities were made the subject of a special law in 1892,* the intention of which was to foster such undertakings and give them the protection of the general government, even in opposition, if necessary, to separate communities. According to paragraph 2 of this law, and the official commentary thereon, concessions for light railways of this kind are given by the ordinary provincial district or township authorities, but such concessions may be refused if the railroad is not considered necessary, or if the financial position of the undertaker does not appear sufficiently stable, and also if, owing to the lack of the traffic, such a road could not pay. If such a railroad is to be operated by electricity or other mechanical power, the president of the provincial district has to decide upon the granting of the concession. All rolling material has to be accepted by a special experienced railway engineer in the government service. The special inspectors take pains to inform themselves so thoroughly that, instead of being hindrances to the introduction of a practical system, they have frequently made suggestions which were helpful to those engaged in the enterprise. One of the questions, for instance, which these inspectors have to pass upon is the efficiency of the brake, a detail which, of course, in the interest of the public, must be under strict control. The law also says that if one builds and runs a railroad according to the concession obtained by him, any person or persons who consider that their rights have been interfered with may attack him for damages, but they cannot cause him to cease building or running the road. As far as the public streets are concerned, light railways have the right of expropriation analogous to that already provided for by law for other means of transport. For cases in which the clause regarding public streets does not apply, the right of expropriation must be granted from time to time, as the occasion may require it. It is therefore foreseen, according to this last paragraph, that cases may come up where property may not only have to be seized for running the permanent way, but also where a seizure or expropriation may be permissible for other purposes, as, for instance, a central station, sub-station, a waiting-room, a car or any structure connected with the operation of such a road. The right of expropriation was established recently in the case of a rosette on a certain house in Berlin where the owner had refused permission to attach the span wires to his house and the setting of a pole instead of the rosette was not feasible.

CARS FOR HIGH SPEED LINE BETWEEN DUSSELDORF AND KREFELD

FREIGHT TRAIN ON BAD-AIBLING–FEILENBACH LINE

ROADBED

In Figs. 19 to 22 are shown roadbed constructions in various towns. The track is laid almost universally on concrete. Some lines in Berlin have been laid on asphalt. In the case where lines are laid in streets provided with granite paving blocks, the authorities usually demand that the rail should have the height of the normal block, about 7 ins. In Figs. 11 to 18 are shown the usual types of rail, which vary in dimensions and material according to the wishes of the various companies and the practice of the various steel works. Berlin, for instance, has chosen a rail heavier, but lower than that used in many other cities, because Berlin has such a large proportion of asphalted streets to take into account. One of the great steel furnishers uses Siemens-Martin steel, another Bessemer, another Thomas' patent steel. The Schmidt lapping-joint is considered very satisfactory in Berlin,

*For translation of Kleinbahn Gesetz see Adams' Report on Continental Street Railways for Massachusetts Legislature.

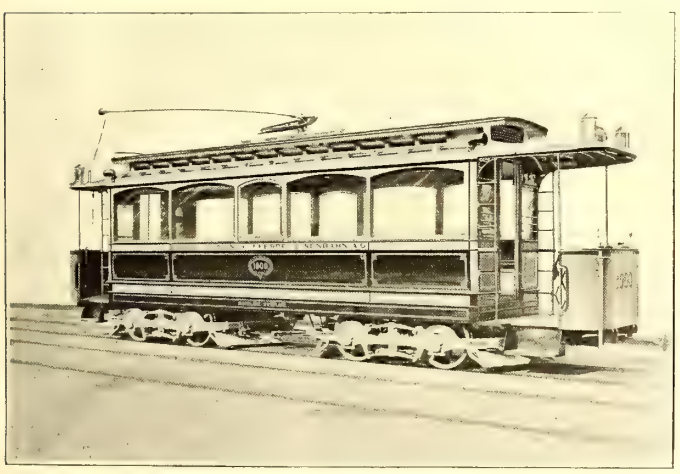
while the Phœnix foot joint is favored in Dresden for instance. The special work such as curves, crossings, etc., has been done to a large extent by contractors especially equipped for that work and not by the furnishers of the rails themselves. The frogs are frequently built of regular rail sections of normal profile, while hardened steel is used for points and centers.

Much attention is given to rail bonding, but plastic and stranded bonds do not seem to have met with great favor perhaps because they are dependent upon the fish-plates, whereas the ordinary ("Chicago") wire bonds are put on entirely independent of the rail joint itself. The fact that the latter bonds have been stolen in several cases, especially in Belgium and Aix-la-Chapelle, would argue in favor of a bond covered by the fish-plate. Fig. 11 shows the type of bond designed and used by the Union Elektricitäts-Gesellschaft in Berlin. About 30 miles of single track in Berlin have been provided with the Falk cast joint, which has given good satisfaction in the case of new rails, but not so good in the case of the old rails. The cast joint has had hardly any further introduction in Germany as yet.

Rail section, Fig. 16, is used chiefly where there are high paving stones. Fig. 17 is the same, but is provided with the Schmidt joint. The section, Fig. 13, is considered very well proportioned and is liked on account of its broad base. Fig. 15 is the accepted profile for the great Berlin lines. The foot is very narrow because of regulations of the city as to a good connection between the pavement and the rail.

The fish-plates vary according to the wishes of the authorities or the companies between 14 ins. and 32 ins. Up to 20 ins. four bolts are used, above 20 ins. six bolts usually. In the case of a fish-plate 32 ins. long the rail bond is one meter (about 40 ins.) long.

ROLLING STOCK

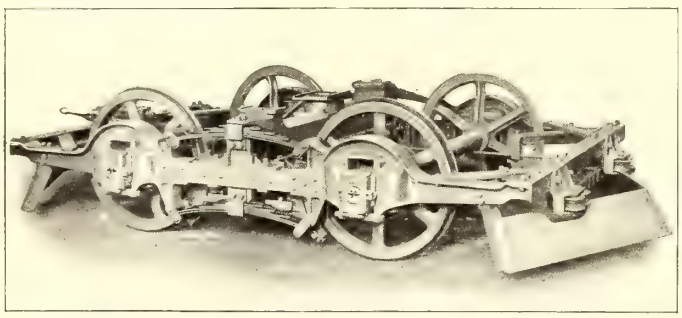


The types of cars are shown in various illustrations.

CAR AND TRAILER IN LEIPZIG

CARS IN DRESDEN

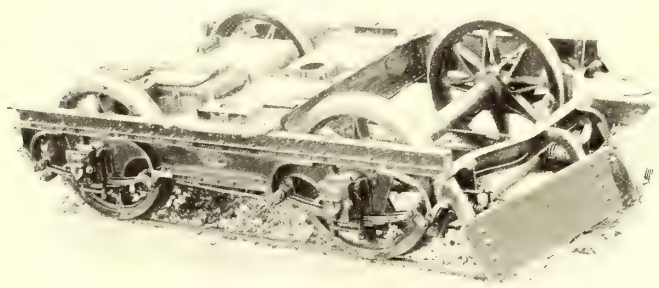
BERLIN ACCUMULATOR CAR



SUBURBAN STATION IN MUNICH

The seats usually run lengthwise, exceptions to this general rule being mostly found in Berlin where a number of modern American cars are in service. The use of trail cars is general, especially on Sundays and holidays. The use of two trail cars is permitted in the city of Berlin.

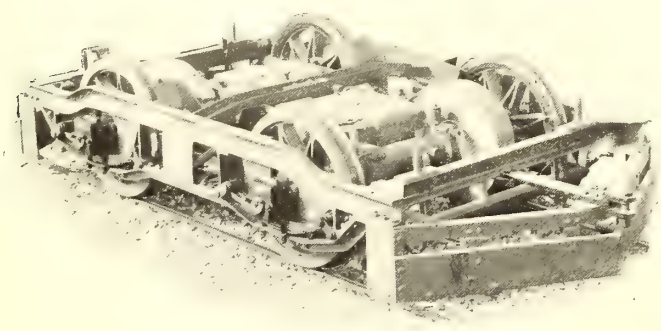
The chief point of discussion regarding car bodies has been the step. In Saxony the authorities rule on the principle that the step should be high enough to allow it to pass over a body which may have fallen on the rails, and therefore give a certain leeway of braking space before the body is touched by any part of the car. In this case the lower step has to be about 14 ins. above the top of the rails. In contrast to this practice, there is a general tendency throughout Germany to make the lower step as



low as possible so that the passenger can get a fast hold, even if the next step is high. But in order to make both steps as easy as possible, the whole platform is kept low and an extra step is provided between the platform and the car floor. The general width of the car is 80 inches.

The distance from middle to middle of track varies greatly, but is usually about 8 ft. The gage is mostly the

BOGIE TRUCK FOR ACCUMULATOR CARS, GREAT BERLIN STREET RAILWAY

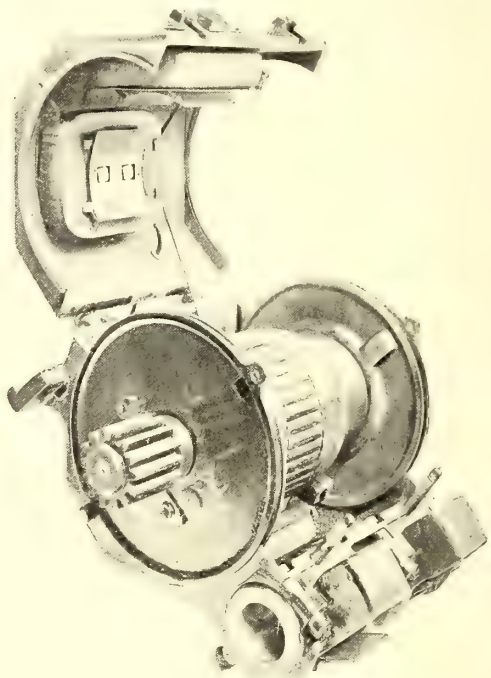


normal gage, 1.435 m. (4 ft. 8½ ins.). If anything below this is chosen it is usually the normal narrow gage of one meter (39.37 ins.). An interurban light railway in Schlesingen has a gage of 75 cm. (30 ins.), and the tracks of the great Leipzig Company having been laid when the

TYPE OF GERMAN MOTOR TRUCK

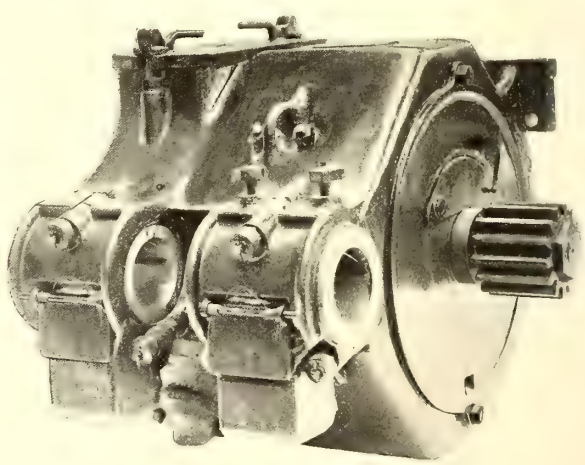
company was in English hands, has a gage of 1.458 m. (4 ft. 9 4-10 ins.).

The largest cars in use are the accumulator cars on the Berlin lines, weighing about 16 tons and holding forty passengers. Passengers are never allowed to stand in the



TYPE OF GERMAN MOTOR TRUCK

cars, and only a certain definite number are allowed to stand on the platforms. The front door is kept closed, the forward platform being reached only from the street. Fares from the front platform are passed through a small hand-hole which is covered by a hinged or sliding door. Bell punches and fare indicator dials are not used, but the passenger receives a ticket upon which all the lines are printed, the line which he pays for, or the limiting point to which he may ride for his fare, being indicated by the punch. The ticket is inspected occasionally by a "Controlleur."



Electric car heaters are avoided as uneconomical. The "Union" has a controller adaptation for electrically-heated cars, whereby the current allowed to pass through the heaters is made to depend upon the intensity of the motor current. When the motors are taking less than their normal full current the heaters may be served, so that the car never consumes more than the maximum necessary for its propulsion, and the heating current does not increase the peaks of the station load.

Heating with "brickettes" of coal in a long tube under

NARROW GAGE MOTOR, OPEN

the bench is the most popular method. The fuel is replenished only twice a day and costs about one cent per

NARROW GAGE MOTOR, CLOSED

hour. Of course, this does not maintain an American sleeping-car temperature.

American trucks served as models at the beginning of the decade but German car builders and one specialist firm, the Bergische Stahl Industrie, are doing good work with standard types of trucks. The latter firm has built and furnished about 3000 trucks (of course, not all for

Germany). Perhaps 80 per cent of the motor cars are equipped with two-axle trucks. Maximum-traction trucks are in use in Munich (page 655), Nuremberg, etc.

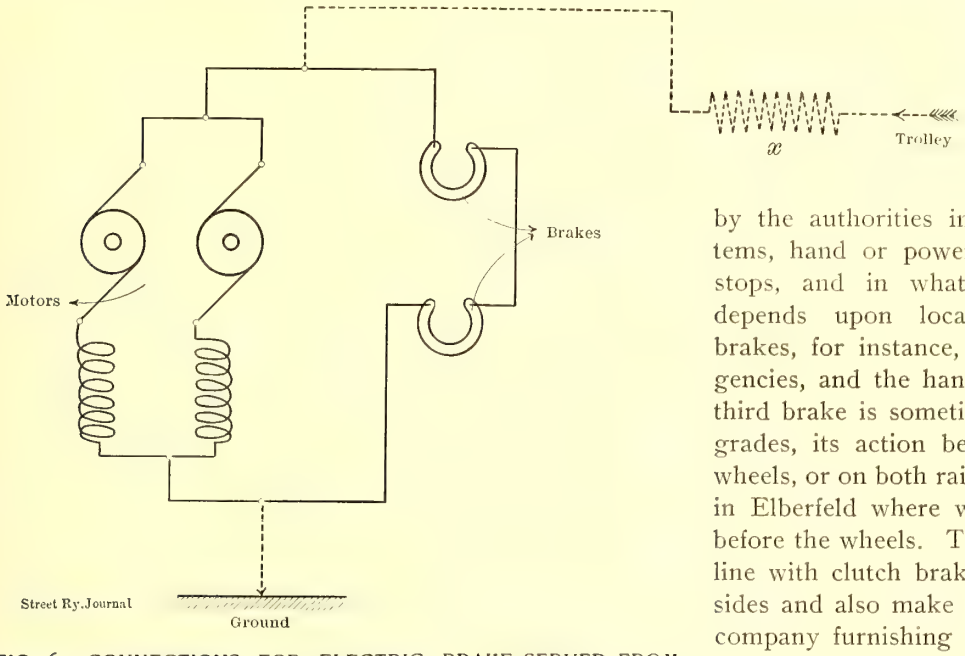


FIG. 6.—CONNECTIONS FOR ELECTRIC BRAKE SERVED FROM TROLLEY WIRE

The bogie-truck of the Berlin accumulator cars is shown on the opposite page.

Preference is divided between cast steel wheels and wheels with renewable tires. The former run some 35,000 miles to 50,000 miles before wearing down to a rim thickness of 18 mm. (.7 ins.).

Brakes have received a great deal of attention in Germany. Every electric car is equipped, first of all, with a hand power brake. This is, in some cases, the old-fashioned crank or wheel type with chain, in others the American ratchet, and in still others a lever working at right angles to the direction of the car and operated in one stroke, or, as a ratchet, in a number of strokes. A second brake, magnetic, or short circuiting, or compressed air, is also installed in many single electric cars, and, latterly, in all cases where the motor cars are expected to draw trailers. In some instances a second brakeman tends the hand brake of a tow-car, but an electric or air brake on the tow-car, served by the motorman, is recognized as a great convenience and safety and is even required by the authorities in Saxony. Which of the two systems, hand or power, is used continuously for regular stops, and in what way their effects are combined depends upon local judgment. The "Standard" air brakes, for instance, in Leipzig, are reserved for emergencies, and the hand brake is employed ordinarily. A third brake is sometimes installed on lines having heavy grades, its action being upon the rails instead of the wheels, or on both rails and wheels as in the case of a road in Elberfeld where wedges are dropped upon the track before the wheels. The "Union" equipped one very steep line with clutch brakes which grip the T-rail from both sides and also make a derailment impossible. The same company furnishing an interesting rack brake on a line where the specifications called for a brake which would act automatically when the speed exceeded a certain limit. Two bosses *o*, (see Fig. 7) on the centrifugal regulator *d*, fixed to the axle *c*, project beyond the periphery as soon as the speed limit is passed, thereby causing the weight *l* to fall. The weight presses the brake shoes *h* against the revolving brake wheels *e*. Between these brake wheels and the toothed wheel *f*, which is not attached to the axle, are placed rubber cushions so that the braking effect is transmitted to *f* with some slip, and without sudden jar.

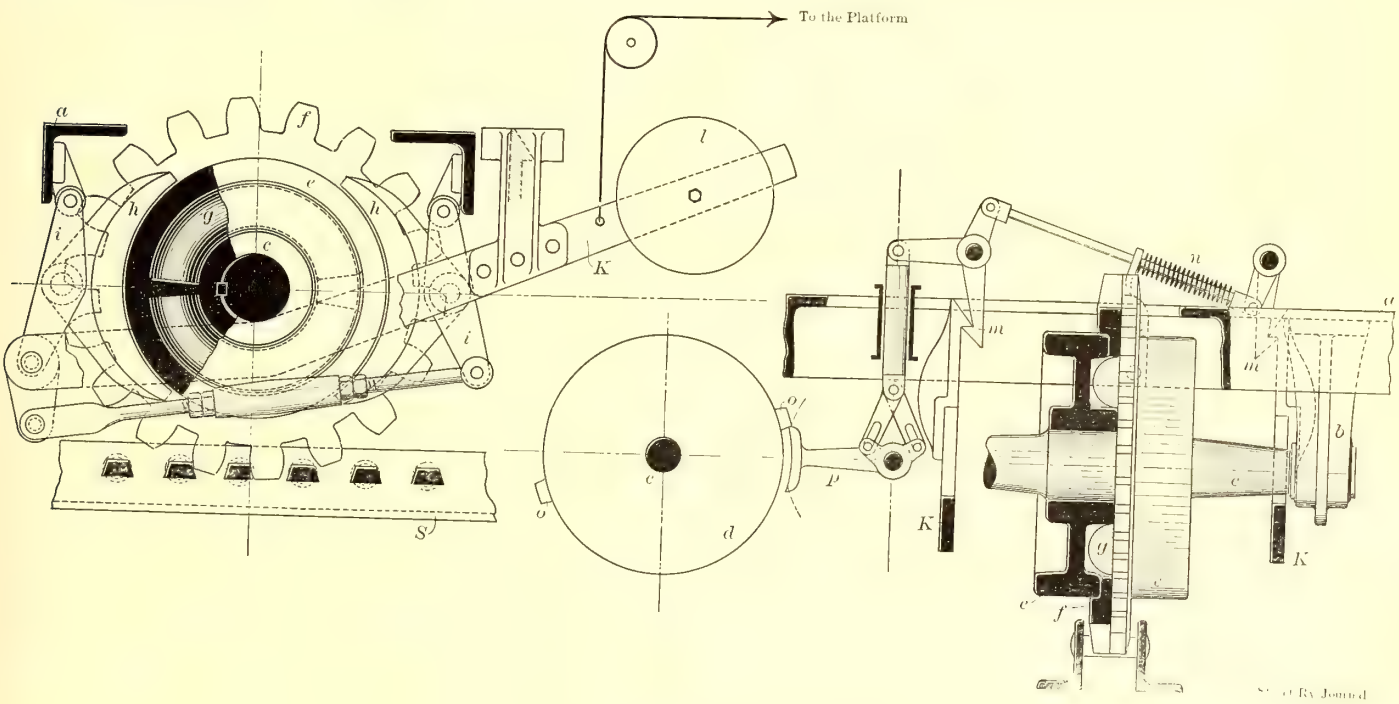

FIG. 7.—DETAILS OF RACK BRAKE

The rack *s* is installed only on steeper parts of the line. The weight is drawn up from the platform and an electric bell sounds until it is drawn up.

To give an idea of the brake systems employed, the "Union," out of 3102 motor cars, installed

398 with simple hand brakes.
461 with hand brake and electric short-circuit brake.
510 with hand brake and air brake.
1733 with hand brake and magnetic brake.

Not to mention a number of cars with rail brakes as above mentioned, magnetic brakes similar to the Sperry are largely used, as are also ingenious types designed by the Union and Siemens & Halske Companies. An interesting combination of a magnetic brake with hand brake on tow-cars is also noteworthy and new. A novelty is an arrangement of the controller whereby, at the last braking notch, the magnetic brake and the motors are

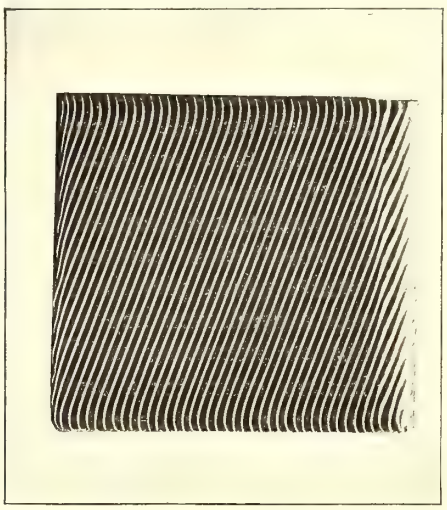

FIG. 8.—MAJERT STORAGE BATTERY PLATE

supplied with current from the line even when the car is standing still—a necessity on grades if one desires to be entirely independent of the hand brake. Fig. 6 shows the connections. The resistance x is to keep the trolley current within limits. The resistance of the motors and brake coils must be so proportioned that the greater part of the current flows through the brakes, otherwise the car will start backwards. The dotted lines show the connections made at the last braking point of the controller.

Series parallel control is general, but space will not permit a discussion of the various types of controllers.

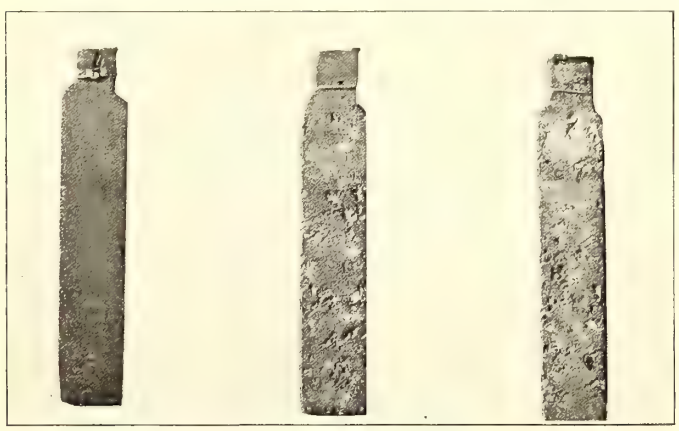

FIG. 9.—CORROSIVE ACTION OF ACID ON THREE KINDS OF LEAD

An interesting divergence from American practice is the double handle controller of Siemens & Halske. One cylinder makes the combinations, and a second is only for cutting out the resistance, step by step. The second cylinder springs back to zero position as often as the first is moved to a new position. It seems rather complicated for the motorman to have to work with two handles.

Another development in controllers is their adaptation

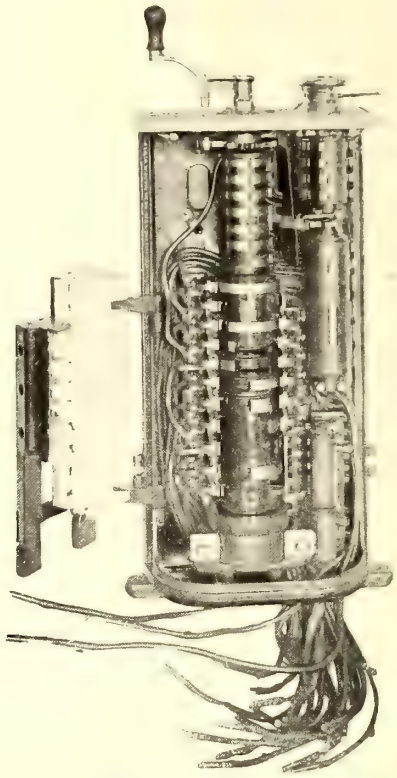

FIG. 10.—CONTROLLER FOR ACCUMULATOR CARS

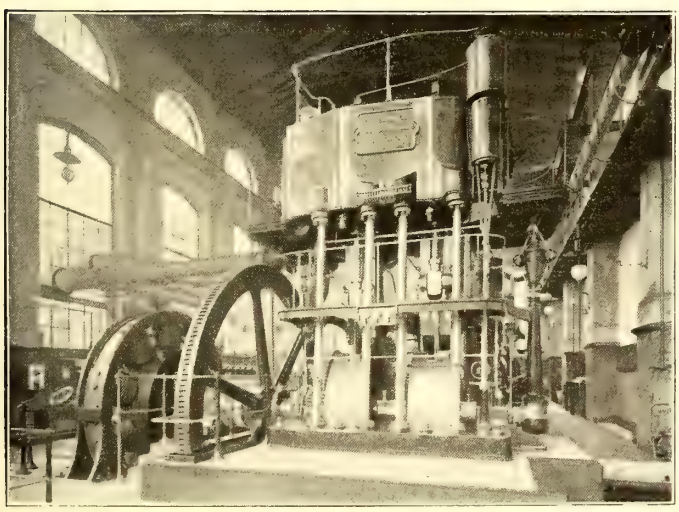
INTERIOR ACCUMULATOR CAR, GREAT BERLIN STREET RAILWAY

to use with accumulators in the "mixed system." In the barrel of a "Union" controller having contacts for electric braking and series parallel control, the accumulator cylinder is placed below, and coaxial with the reversing

cylinder, and is actuated by the wheel above the reversing lever. This cylinder has three positions:

1. Trolley alone.
2. Trolley with charging circuit.
3. Discharging current.

The lighting current is also modified by this cylinder. A small resistance is placed in series with the battery for a moment at the beginning of its charge to avoid the

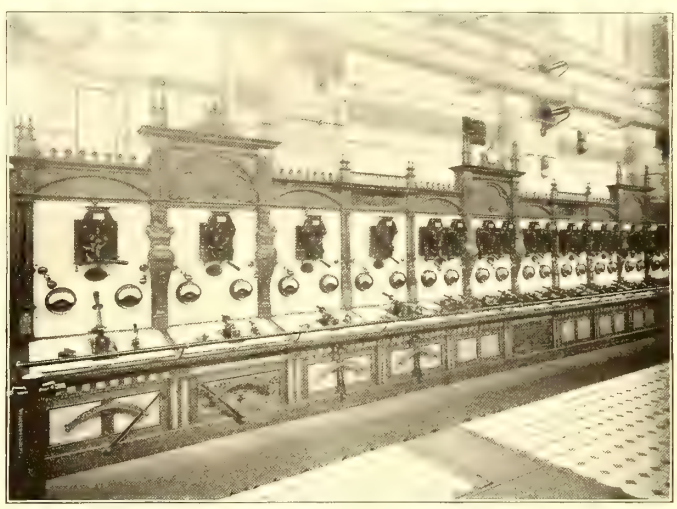


EXTERIOR POWER HOUSE, GREAT LEIPZIG ELECTRIC RAILWAY

otherwise heavy rush of current. A charge indicator is also provided to avoid the loss and disagreeable gas from overcharging.

American practice has been followed with motors as with controllers. On page 656 is shown a motor built by the "Union" for a gage of 75 cm. (29½ ins.).

DISTRIBUTION SYSTEM



The feeders are, as a rule, underground. Almost uni-

ENGINE GENERATOR UNIT IN POWER STATION, GREAT LEIPZIG RAILWAY

versally lead covered cables provided with an iron ribbon armor are laid directly in the earth without further protection, or, at most, covered with brick or slabs of stone. An insulated return feeder is connected to the rail at the same point at which a feeder is connected to the contact wire in Berlin, but this practice is not very general owing to the great expense, and the traffic is not heavy enough on most roads to make it necessary.

The types of ornamental iron poles generally used do not vary much excepting that the ornamental base, the rings and the cap are designed to suit the taste of various city authorities. Wooden poles are rarely seen, but iron poles of lattice work construction are sometimes met with in smaller towns. Side brackets and double brackets are used wherever possible. Overhead feeders are avoided excepting in the country. The hard drawn copper trolley wire is supported usually by span wire of 2 mm. and 3 mm. diameter. Line insulators, that is, those types which were most serviceable and had a neat appearance, were imported from America for some years, and a good many American supplies are said to be sold now, but the German rubber companies and other manufacturers are delivering overhead supplies to the electrical companies which meet all the conditions at least as satisfactorily as the best known American types, and at a reasonable price. Also several firms of specialists have established themselves for just this line of business. The general character of the overhead construction may be said to be good, and in the larger cities where difficult problems have had to be worked out, some very interesting and exceedingly clever work has been done with overhead construction, and one rarely hears any complaints on the part of the public as to the appearance of the trolley lines.

SWITCHBOARD, GREAT LEIPZIG RAILWAY

The loss in the feeders and difference of potential between different parts of the system, points which are controlled in England by the Board of Trade regulations, are not officially specified in Germany. The electrician of the city of Berlin has interested himself especially in this feature of electric distribution, and has written a good deal about it, but the specification for the installation of electric roads in Berlin does not state any figures, the idea being that measurements, from time to time, will be more efficient to prevent trouble than a stiff rule.

The only conduit system in operation in Germany is a line 1.3 miles long, built by Siemens & Halske for their own road which starts in the best business portion of Berlin, and joins an overhead line later. The conduit line has been running fairly regularly since the spring of '96, with thirty-five cars. As in Budapest, the conduit is placed under one of the rails, an arrangement which every European engineer seems to prefer to the center conduit which requires more iron in the street. When the car

reaches the end of the conduit division, the plow is raised from the conduit automatically by an inclined plane.

POWER STATIONS

The largest street railways are in cities with extensive lighting stations, and the current is usually delivered from the one or more lighting stations at 550 volts. Rotary converters or transforming sub-stations have only been used in isolated cases.

The capacity of the dynamos used for furnishing current for the street railways in operation was, according

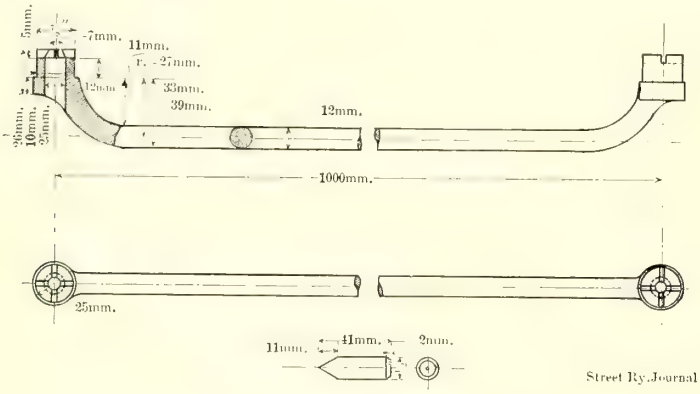


FIG. 11.—U. E. G. STANDARD RAIL BOND

besides those above mentioned the roads get their current from combined light and power stations owned by companies, as, for instance, in Berlin.

One of the most important power stations for street railway supply is that of the Hamburg Electric Company. This company has other stations more especially for lighting. In this station there are seven vertical triple-expansion engines, each for a normal load of 1000 h.p. at ten atmospheres and 100 revolutions; five are from the Augsburg Company and two from Schichau & Company. Five of the engines drive each two Schuckert dynamos of 400 kw. capacity each, while the other two engines each

GERMAN TYPES OF RAILS AND JOINTS

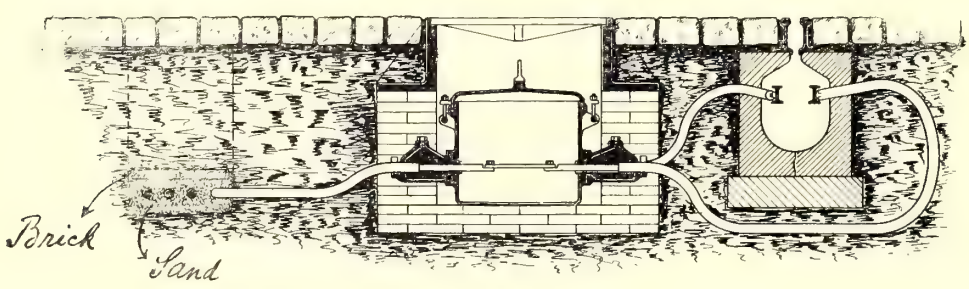

FIG. 19—ARRANGEMENT OF UNDERGROUND FEEDERS

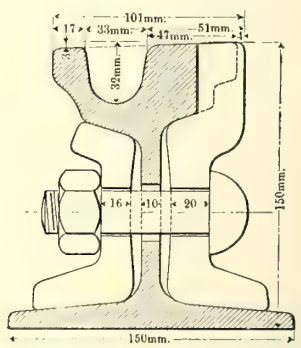

FIG. 18

to the latest statistics, 33,333 kw., to which should be added 5118 kw. in accumulators in the stations. The use of Puffer batteries to equalize the load in street railway power stations is generally recognized as a highly economical feature, and is on the increase. The average kilowatts installed in machines per mile of track is thirty-four, and average kilowatts installed per motor car is 14.2 In the case of the forty-four roads receiving current from special railway power stations, in about a dozen cases current is taken from electric works owned by towns, as, for instance, in Munich and in Dresden, in which latter case the city has in addition to its lighting station a special central station only for the street railways. In all cases drive 800-kw. Schuckert dynamos. While most of the dynamos are wound for 500 volts to 600 volts, four are wound for 250 volts to 300 volts so they can supply lighting current and (two coupled in series) railway current. A battery of 275 elements with a capacity of 2000 amps. discharge is connected in parallel to the railway generators and secures an even load, besides constituting an excellent reserve with the capacity of one steam engine unit during one hour.

STORAGE BATTERY CARS

When three such important cities as Hanover, Dresden and Berlin are dependent on the use of accumulators

for carrying out a successful electric service, one naturally asks what is the novel feature which makes the lines in these cities possible, whereas accumulator traction in general has failed to be satisfactory. The first essential factor is that the cars do not have to stand in the sheds while the batteries are being charged, and the batteries do not have to be removed from the cars, but are charged as above mentioned on the trolley line. The second factor is that instead of trying to use any of the so-called high capacity batteries, the street railways mentioned are using batteries supplied by firms which have long ago recognized that there is not any light weight substitute for lead, and that a sacrifice in weight would mean for a traction battery so much more expensive renewal. Up to date there are no really precise figures to be obtained on the cost of maintenance of such batteries over a long period. A car battery costs about $1,300, and 15 per cent to 20 per cent of the original cost will have to be given out or laid aside in the reserve fund each year for maintenance of the battery for ten years.

Aside from the well known Tudor accumulator, the element which has been installed in a good many of the Berlin cars and is ordered for a large number more has excited a good deal of interest in the technical world as having some points of novelty and some advantages which put it, perhaps, at the head of traction accumulators to-day. It is the invention of Dr. Majert, a chemist in Berlin. The invention relates to a mechanical process of preparing the plate, not from cast lead, but from homogeneous rolled lead. The flat rolled plate is furrowed something like a plowed field. A peculiarly formed cutting tool shaves up a thin leaf of lead and causes it to stand upright at right angles to the core of the plate.

With cast plates the exposed surface is eight to nine times that of the external dimensions of the plate, whereas with the Majert plate, a surface eighteen times as large as the original plate is obtained. With the cast plates of other systems a conical structure is formed which has the disadvantage of weakness on the outer and thinner parts of the ribs, which are consumed more rapidly than the parts nearer the core, and the plate thus loses a part of its useful surface. The manufacturers of the Majert plate attach great value to their being able to use rolled lead on account of its ability to withstand the attacks of the acid much better than cast lead. In Fig. 9, page 658, are shown three pieces of lead "formed" together during the same length of time with the same current intensity and in the same electrolyte. The plate at the left is of rolled lead, the middle one of cast lead, subjected to a pressure of 2500 kg. per square centimeter, and the plate to the right is ordinary cast lead subjected to no pressure. The uniform molecular formation of the latter especially rendered it very much more subject to corrosion than the rolled lead.

The Majert Company claims that during nine months in batteries running on the lines of the Berlin Railway, the plates were charged and discharged 3200 times without showing the least disintegration. The Majert plates described are used for the positive plate and are Planté formed. The negative plate is cast and pasted as in other systems. A great deal of very valuable experience has been gained in lining the car for the reception of the cells so as to avoid any deleterious effect from acid and fumes. A very tightly-fitting double cover had to be provided also. A current of air passes through the battery space through large tubes having funnel outlets on a level with the roof of the car.

Plates which have run 20,000 automobile car-miles seem to be in perfectly good condition, and from estimates by the reduction in the weight of the plates they ought to be expected to run about 40,000 automobile car-miles.

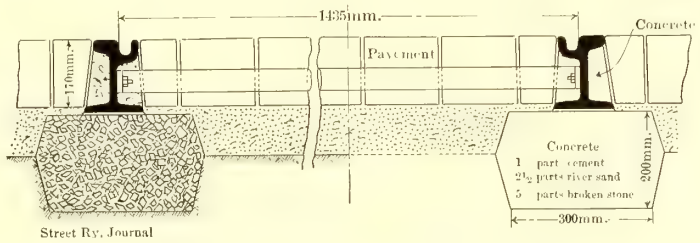

FIG. 19.—ROADBED IN MAGDEBURG

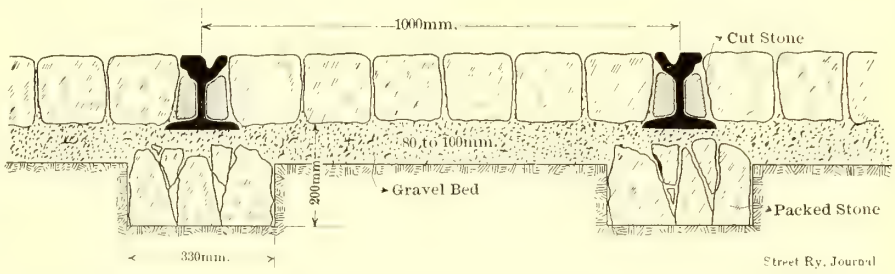

FIG. 20.—ROADBED IN ELBING

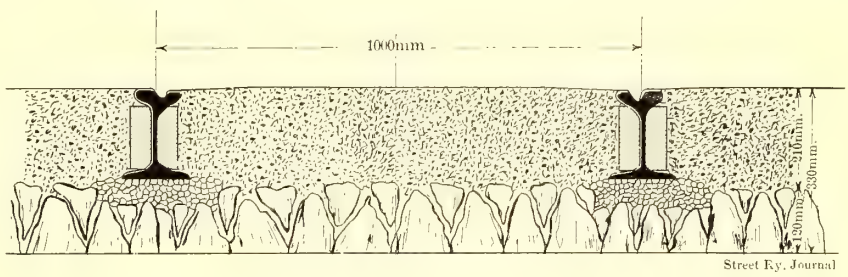

FIG. 21.—SECTION OF TRACK FOR MACADAMIZED STREETS

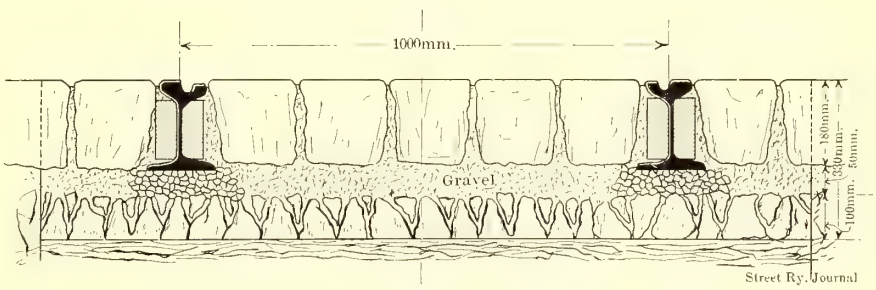

FIG. 22.—SECTION OF TRACK FOR PAVED STREETS

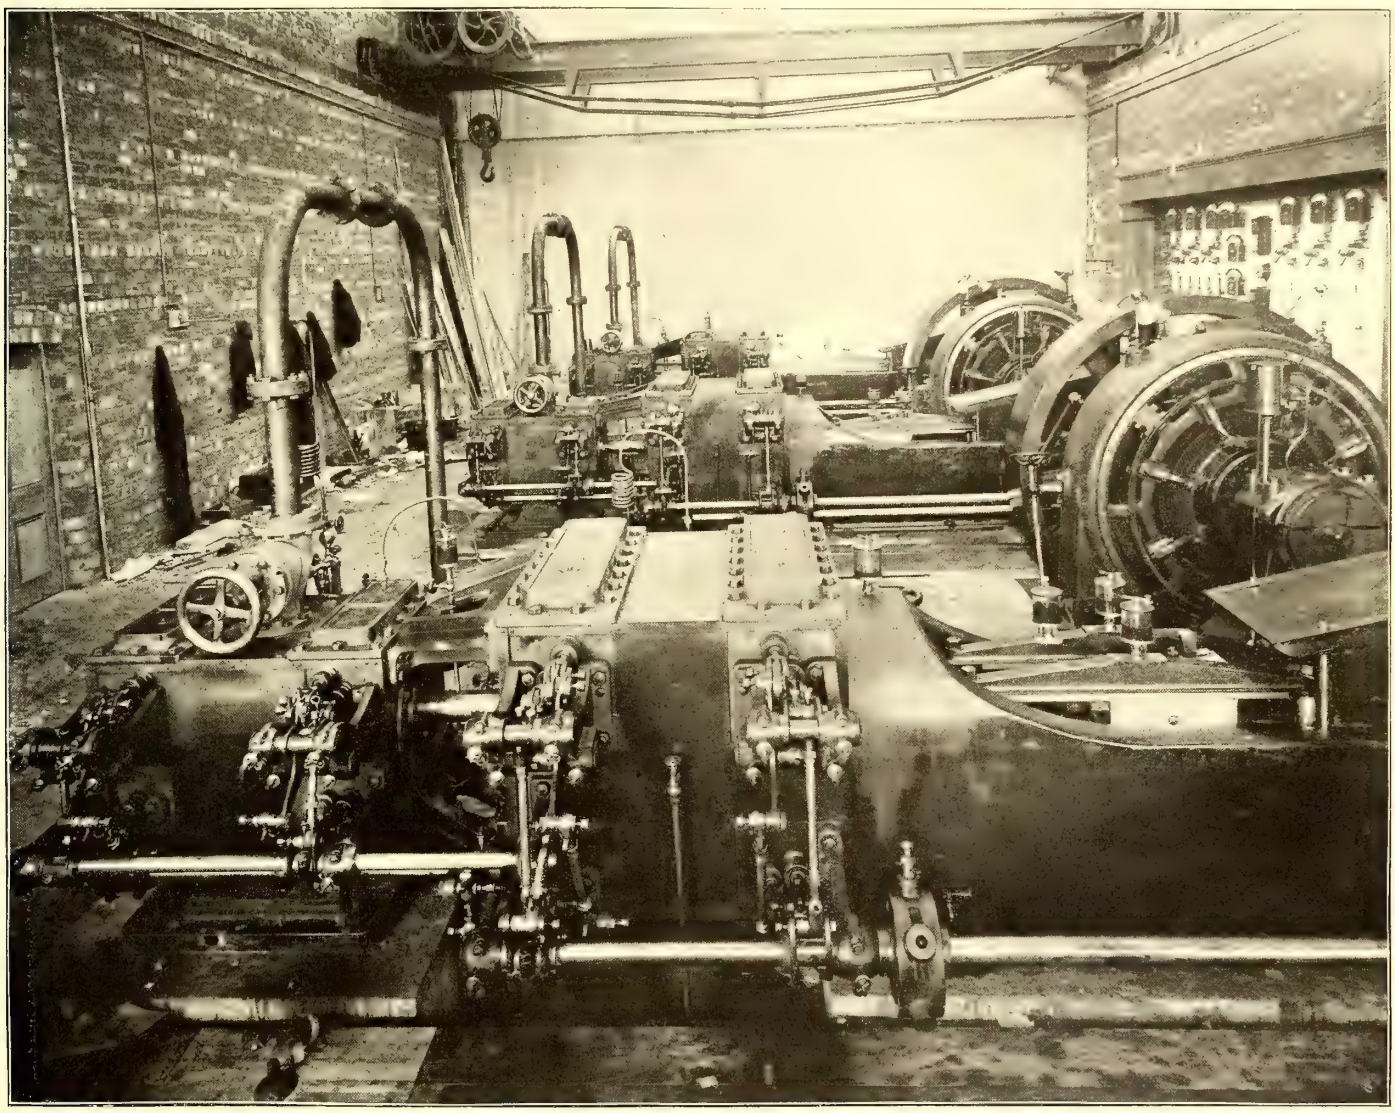
A good idea of the general appearance of the face of the Majert plate can be obtained from Fig. 8, on page 658. Another engraving on the same page shows the method of carrying the batteries on the cars of the Great Berlin Street Railway. The tops of the longitudinal seats are raised, exposing the cells underneath. A view of the inside of the controller used with these cars is also given.



CAR HOUSE IN SOLINGEN

ELECTRIC RAILWAY PRACTICE IN GREAT BRITAIN

BY SIDNEY H. SHORT*

Electricity as a motive power for tramways is fast becoming popular in the British Isles. Had it not been for the fact that most of the tramway concessions in Great Britain were made under the tramways' act of 1870, running for twenty-one years, electric tramways would to-day be pretty general throughout England. In all of the concessions granted under this act there was a provision that at the expiration of the grant the municipal corporations could, if they so desired, take over the tramways. As these concessions have only recently expired, most of the corporations, of which Glasgow is an example, are taking over the tramway systems and are fast converting them into electric lines. Some of the lines have already been equipped and are in operation. The city and town corporation authorities are making every effort to give to their constituents the best possible transportation facilities, and are thoroughly alive to the advantages of electric traction. Municipal ownership of the tramways is therefore the rule in large cities like London, Glasgow and Liverpool, and these cities are being followed by the smaller towns, although there are many that have recently granted franchises to private corporations under the tramways' act.

INTERIOR OF PRESENT POWER STATION, GLASGOW CORPORATION TRAMWAYS

There are now in operation in Great Britain forty-one electric trams having 300 miles of single track, of which 69 miles are owned and operated by municipal corporations, and 231 miles by companies. Twenty roads are in process of construction, having 264 miles of single track,

*I wish to thank the following gentlemen for the information, photos, drawings, etc., which they have so kindly furnished to be incorporated in this article:

C. Challenger, traffic manager, Bristol.
Arthur Ellis, M. I. E. E., borough electrical engineer, Bolton.
Alfred H. Gibbings, city electrical engineer, Bradford.
A. B. Holmes, M. I. C. E., city electrical engineer, Liverpool.
R. E. Quin, electrical engineer, Blackpool.
Henry E. Stilgoe, borough engineer, Dover.
John Young, general manager, Glasgow.

61 miles of which are being built by municipal corporations and 203 miles by private companies. Ninety-two roads are projected, seeking parliamentary powers, twenty-two by municipal corporations and seventy by private companies.

A large number of the tramways within municipal corporation limits are owned or leased by private companies made up of local people; on the other hand, a great many cities and towns have assisted syndicates, formed for the purpose of building and operating electric lines, in securing from Parliament the right to construct and equip lines within their limits. Chief among these private corporations or syndicates may be mentioned the British Electric Traction Company, the New General Traction Company and the General Electric Tramway Company.

The greatest field, however, for the operation of private corporations is in building interurban electric lines. England especially is so thickly populated that the distances between large centers of population is small. Liverpool and Manchester, for instance, are but 30 miles apart, with a population of nearly 1,000,000 people in each place.

It is difficult to say in which branch of electric railroad construction there is the greatest activity. Nearly all the municipal corporations are either building electric tramways or applying for the right to do so, while private capital is seeking parliamentary powers under what is known as the "light railway act," to build interurban and suburban lines in nearly every part of the country.

Where franchises are granted, the term, as provided by the tramway act and also by the light railway act, is for twenty-one years. There are no special burdens attached to these grants in the way of paying to the local authorities a percentage of the gross receipts, or paving entire roadways, unless, indeed, the promoters make propositions to the local authorities containing provisions of this character to secure their consent and their assistance in obtaining the necessary grants from Parliament. Local authorities are usually anxious to secure electric tramways, not only because of their convenience, but because of the reduction of their general tax rates, which the taxation of tramway companies brings about.

In applying for a grant from Parliament for a tramway, either within municipal limits or across country, plans must first be submitted to the Board of Trade and their approval secured. By this board the maximum speed of the cars, the number of passengers to be carried by each car, the location of the tracks, and, indeed, every other detail is carefully regulated. Under the corporations' act periodical financial reports are made and certified to by chartered accountants, so that the financial condition of any tramway company, or, in fact, of any limited company under this act, can be ascertained at any time. These precautions are not limited to the interests of the public, they extend to the investor as well.

MOTOR CAR AND OBSERVATION CAR, DOUGLAS & LAXEY ELECTRIC RAILWAY

In many ways the rights of vested interests are considered. There is no disposition to create unnecessary or disastrous competition. Parallel lines cannot be constructed until it has been clearly shown that the public will be better served by them and the undertaking will in all probability be a financial success.

Under such supervision there is very little possibility of over-capitalization and of success for schemes not based upon thoroughly good financial principles. This fact certainly conduces to the solidity of undertakings in Great Britain, and accounts in a large measure for the good results obtained in almost every instance by tramways, nearly all of which are doing a good business and are paying good dividends.

The field for electric tramways in Great Britain is exceedingly large. London must look in this direction for

relief for the congested traffic of her streets, as the amount of space now taken up by the omnibuses and hansom cabs is altogether out of proportion to the number of passengers carried. It can be demonstrated that if the 'buses of London and a large proportion of her hansom cabs were replaced by rapidly moving tram-cars the streets would be comparatively free.

ROAD-BED CONSTRUCTION

The road-bed construction for electric traction in Great Britain is reduced to standard practice, and it is interesting in that it differs so much from American practice. The conditions existing in the streets of cities in this country permit of a construction which would not succeed in the streets of American cities. The streets and roadways, it must be remembered, are hundreds of years old, and are made of macadam partly cemented together by a natural form of hydraulic cement. This is especially the case in the southern portion of England, where there exists so much lime and flint that the road-beds become hard and solid for many feet in depth. It is necessary to excavate these streets only to a depth of 13 ins., and to lay in a 6-in. layer of concrete made from broken stone and Portland cement. Upon this concrete the rails are laid with tie rods at intervals to keep them to gage. The paving blocks are then set in the usual way, grouted with cement, or filled with coal tar pitch, no sleepers or ties being necessary. In fact, the use of wooden sleepers would be objectionable where such an excellent foundation has been provided by the years of constant care and attention which these magnificent roads have received.

The following is the excellent specification for road-bed construction, recently issued by John Young, manager of the Glasgow Corporation Tramways, and will serve to give an idea of the standard construction for cities. It may be said in addition that specifications are in all cases adhered to closely, the greatest care being taken to follow them in practice.

GLASGOW SPECIFICATIONS FOR TRACK LAYING

Concrete—The concrete under the new tramways, and where renewed for existing tramways, shall be 6 ins. in depth, and shall consist of four parts of clean whinstone, broken to pass in every way through a 1½ in. ring, two parts of sharp sand, and one part of Portland cement. Where concrete may be found already existing, and fit for the purposes of the work, such concrete shall not be interfered with, but it shall be smoothed off, where necessary, with a layer of fine concrete, as after specified. The concrete for bedding pipes to be made with clean, hard clinkers or whinstone, broken to pass through a ¾ in. ring, and mixed with sand and cement in the same proportions as last.

The cement shall weigh 115 lbs. per imperial straked bushel, and shall be so finely ground that at least 90 per cent shall pass through a sieve 2500 meshes per square inch. It shall be kept in a waterproof store near the works for fourteen days, and shall be of such a quality that a sample taken from bulk and mixed neat in a mold immersed in water for seven days shall resist, without breaking, a tensile strain of 400 lbs. per square inch, and it shall not be used until tested and passed, the contractor supplying the necessary samples free of charge. The contractor shall also deliver to the general manager a certificate by the makers of the cement guaranteeing that the cement is conform to specification.

All sand shall be clean, sharp river or pit sand, free from clay, coal or earthy matter. A sealed sample to be submitted before the offer is accepted.

All materials for concrete shall be separately measured in boxes of equal length, breadth and depth, at sight of the inspector; a separate box to be provided by the contractor, free of cost for each of the different materials, of such capacity that one measure of each shall form a batch; it shall be laid on clean, hard boards, carefully mixed and turned over twice when dry, afterwards watered from a vessel or pipe having perforated nozzle; sufficient water, and no more, to be used than necessary to thoroughly incorporate the ingredients, and again turned over, at least twice, by workmen specially chosen and expert at such work.

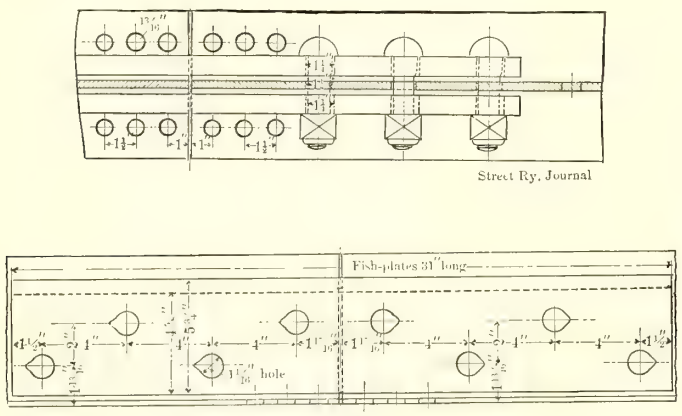
The upper surface of all concrete, including the upper surface of existing concrete which may be left undisturbed, shall be smoothed off with a layer of fine concrete, composed of four parts of fine clean whinstone shivers, broken to pass through a ½ in. riddle, one part of sand, and one part of Portland cement. The finished surface shall in no case be more than 1 in. below the under surface of the paving stones. The contractor shall also carefully pack the rails throughout with this fine concrete, so that they will rest throughout upon it, and that there will be no hollow or vacant spaces. Where the space under the rails does not exceed ½ in., the rails are to be set in plastic cement formed of two parts sand to one of cement, and where the space exceeds ½ in., it is to be formed with fine concrete packed in with a beater pick. The rate for rail-laying to include the cost of all concrete or cement used for packing rails.

Rails and Fishplates—The rails and fishplates shall be of steel, and will be supplied by the corporation. The rails are of girder section, weighing about 98 lbs. per yard, and the fishplates about 74 lbs. per pair. These will be delivered to the contractor at Coplawill or Kinning Park depots. In the event of there not being a sufficient quantity for the respective sections at the depots named, the balance shall be taken from the quay ex ship or railway station ex wagons as and when they may be received. The contractor shall be responsible for the full quantity received, and have the same weighed on corporation weights, at his own expense, and hand in the weigh tickets at the general manager's office. The contractor shall also provide safe storage for them till required. The majority of the rails shall be in 60 ft. lengths, the remainder in 45 ft. lengths.

Rail Laying—The rails shall be laid on the concrete formation. They shall be tied with twelve tie bars for each rail length of 60 ft., fish-jointed with eight 1-in. fish bolts and nuts to each joint, and laid to a gage of 4 ft. 7¾ ins., measured to the outer edges of the grooves. Cramp gages placed every 4 ft. to be used, and only removed when the causeway is laid. The rails shall be butted close together at the joints, and in any cases where the rails do not exactly coincide, the contractor shall file them fair, the cost of filing to be included in the rail laying.

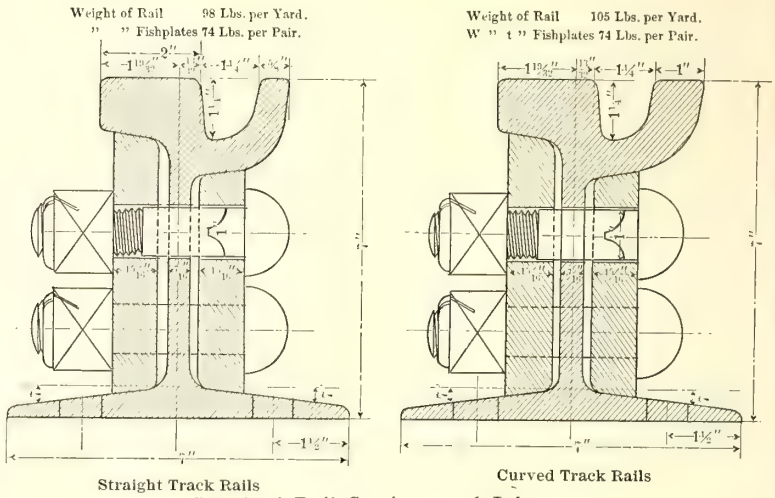
The joints of all rails on the straight shall be opposite each other for both lines, and on curves the joints shall be squared every 120 ft., and the contractor shall arrange the position of the service crossovers, if any are used, so that there shall be no cutting; 60 ft. rails to be used throughout. Temporary closers must be cut from old rails.

All temporary crossovers required for working the tramways traffic shall be supplied, laid down, maintained and shifted by the contractor. A man, at the contractor's expense, to be placed at each crossover during the hours the cars are running, to attend to the points and crossings. The cost of providing and maintaining these crossovers to be included in the contract price for rail laying.



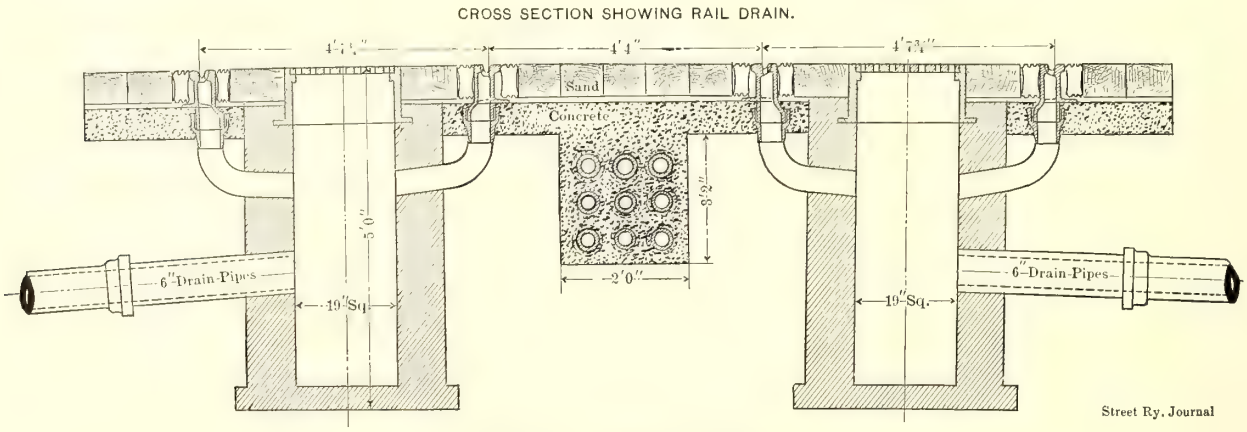
The inner rail of each line shall, as a rule, be laid ¾ in. higher than the outer, but the engineer shall have power to regulate the relative heights. The concrete shall be cut, if necessary, to attain the slope.

The contractor shall bend the rails for all curves on a level floor or platform, which he shall provide for the purpose, to the exact radii of the curves previous to laying, and provide templates of the different curves. The crow used for bending rails shall be made to fit the full section of the rail on both sides, and the power shall be applied at the neutral axis of the rail to avoid twisting or damaging the rail. Not more than 4 ins. at each grip of the crow will be allowed. All unevenness or twist must be taken out of the rails by the crow, whether on the curve or straight line, and the whole rail laying made true, regular and eye-sweet. Any rails, fishplates, or other material destroyed by imperfect workmanship in bending, cutting, or otherwise, the contractor shall be held responsible for, and the difference in cost between new and scrap rails shall be deducted from his account.

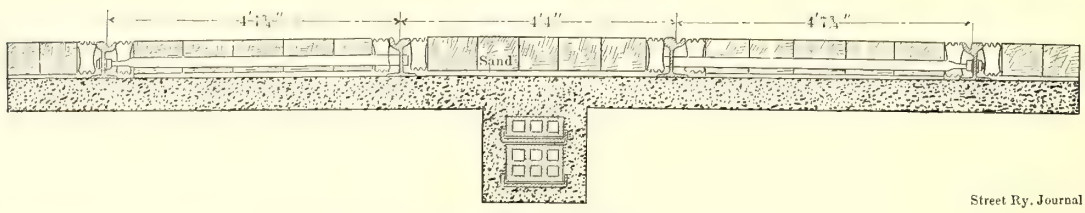


The corporation reserve power to provide and lay all special

work with their own men, and all such work shall be excluded from the contract. Where special closing pieces of rail may be required, the same shall be cut by the contractor with a cold saw. Cutting with the cold chisel will not be allowed.



Where crossings, junctions, curves, or other causes require rails to be cut or additional holes for fish bolts or for tie-bars to be bored, these holes shall be bored by the contractor without extra charge; and where it shall be necessary to have longer or shorter tie-bars, the contractor shall make the necessary alterations on the ordinary tie-bars as they are supplied by the corporation; and where, from any cause whatever, the bolt holes do not coincide with those in the fishplates or otherwise the contractor shall cut the rails, bore the additional holes, or enlarge such holes as may be required with proper tools for the purpose, and, in short, he shall do everything requisite for making good all defects and laying the tramways in perfect and proper order, and that without any extra allowance or claim whatsover.



Fish-Plates

Standard Rail Sections and Joints

GLASGOW ROADBED.

DETAILS OF ROADBED PRACTICE IN GLASGOW

Where new rails have to be substituted and laid for existing rails, the original concrete and sleepers forming the substructure shall not be interfered with, excepting where the levels are altered, but the new rails shall be laid in proper line and level. Where the new rails join the existing rails, the contractor shall cut, joggle and bore the rails and fishplates to suit the section of the different rails to ensure a proper connection.

Water Gratings—Water gratings shall be formed by the contractor on the rails where required, and form the connections to manhole and drains, as shown on drawings. Contractor is to cut the trench and build the brick work, and lay and joint the pipes with cement, and make good the brick work and concrete, and fix the rails in position. The pipes, bends, manhole covers and special castings for these will be supplied by the corporation.

Points and Crossings—The points and crossings, and all special work, including gussets or angle blocks for same shall be supplied by the corporation ready for laying, and the contractor shall take delivery of them at any place within the city that may be pointed out.

The points and crossings shall be fished to the rails. The cost of laying and fixing the angle blocks or gusset pieces shall also be included in the price for laying points and crossings.

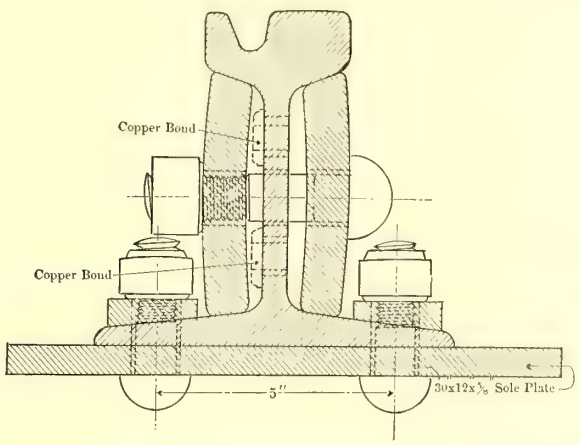
Bolts and Nuts—The bolts and nuts for fishing rails shall be supplied by the corporation to the contractor at the rate of 16s. per cwt.; he to take delivery at Coplawhill Stores. Weight of 1-in. bolt and nut about 30 ozs.

Tie Bars—The rail shall be held in gage by tie bars, also to be supplied by the corporation to the contractor at the rate of 12s. per cwt. at Coplawhill Stores. Weight of tie bar, about 13¼ lbs.

Chilled Paving Blocks—Chilled paving blocks shall be laid on each side of every rail, alternately with the paving stones, averaging about thirty-two blocks per lineal yard of double line. The blocks to be carefully hard bedded on the sand. Power is reserved to dispense with the chilled paving blocks on all or any portion of this contract.

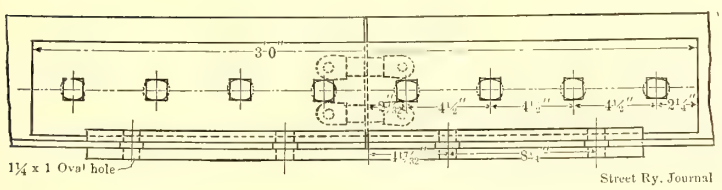
The paving blocks will be supplied by the corporation to the contractor at their contract price of £5 per ton, delivered at the nearest N. B. railway station. Contractor to take delivery and pay for corporation weighing. The average weight of each block is about 9.26 lbs., and they measure 4 ins. x 3 ins. on the surface.

Weighing Materials—The weight of chilled blocks, tie-bars, bolts and all other iron or steel work taken over by the contractor from the corporation shall be fixed by the measurers in the presence of parties to this contract, by actually weighing a quantity of each to ascertain the average weight, and the weight shall be calculated according to the number of the various articles furnished to the contractor by the corporation—the contractor being responsible for all loss.



Sand—A layer of sand, not more than 1 in. in thickness, shall be spread over the concrete in which the paving shall be set. The contractor shall be careful to keep the joints of the paving free of sand, and to use no more of it than is requisite for bedding the stones. All sand shall be clean, sharp river sand, free from coal or other impurities. A sealed sample shall be sent in along with offer for approval, and if approved will be held to be an average sample of what is to be supplied for the whole contract.

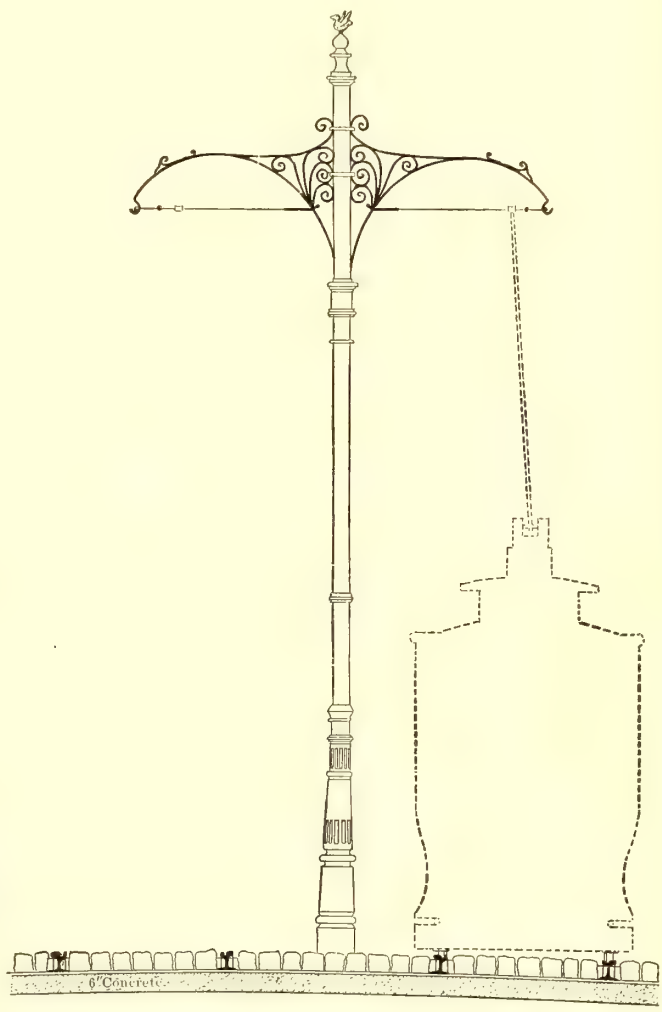
Causewaying—All new paving setts will be supplied to the contractor by the corporation and charged to him at the rate of 28s. per ton. The contractor to take delivery at such of the following places as shall be intimated by the general manager, viz.: The wharf of the Clyde Navigation Trustees, or of the Forth and Clyde Canal, at any of the railway stations within the city, or at any depot or street in which they may for the time being be stored, and the contractor will be bound to remove the stones from the places so intimated to the streets in course of being causewayed immediately after receiving instructions from the general manager; and in the event of his refusing or delaying to remove the stones, the corporation shall have power to do so, and the contractor will be held liable for all expense thereby incurred, the amount to be deducted from any sums due the contractor. The contractor shall also be bound to weigh every cart of paving setts so removed on the corporation weighs, and deliver up the weigher's ticket to the inspector on the job, with each cart, before it is discharged. The weigher's charges shall be paid by the contractor.



The breadth of paving, including chilled blocks, for the double line of tramways shall be 15 ft. 8 ins., excluding the breadth occupied by rails, and for single line 7 ft. 6 ins., and it shall in all cases extend to 18 ins. beyond the outer edges of the rails.

On the outside of rails the paving shall be properly coursed and jointed with existing paving, and the contractor shall lift and relay so much of the existing paving beyond the formation width as may be necessary to ensure a uniform and properly finished roadway. All the old paving stones which are fit for redressing shall be redressed and used as far as possible, with a proportion assumed, in the meantime, at 20 per cent of new stones laid along each side of the rails. Where there is not sufficient quantity of old stones to pave the track in this manner, the engineer shall determine the portions that are to be paved entirely with new stones. The openings for cross bonding in all new work to be temporarily filled in until after testing is done, thereafter the contractor to open out to admit of fixing cross bonds, and then fill in and grout the same.

All new and old paving setts shall be square-dressed, from 7 in. to 11 ins. long, 6 ins. deep, and 3½ ins. to 4 ins. broad. Power is reserved to lay certain portions of the tramways, and also the crossings, with setts 4 ins. sq. by 6 ins. deep. The paving shall be laid in straight and parallel courses, so that the cross section shall have a uniform course on each side of the center of the street or of the tramway, and the finished level next the several rails shall be uniformly and truly level with the rails. The stones shall be set as close as possible to each other, break bond to at least one-third of their length, and the courses next rails must butt truly and hard against the head of the rail, and rest to the extent of at least 1½ ins. on the flange of rail. A straight-edge to be used for every course; not more than ⅜ in. of round will be allowed between the rails. Where the tramways are laid in Macadam streets, the causewaying outside the rails shall break bond at the outer edges, and shall be of an average width of 18 ins. No extra price will be paid for breaking bond,



Rail Section and Joint

Fish-Plate and Bond

DETAILS OF ROADBED PRACTICE IN BRADFORD

LIVERPOOL ROADBED AND CENTER POLE CONSTRUCTION

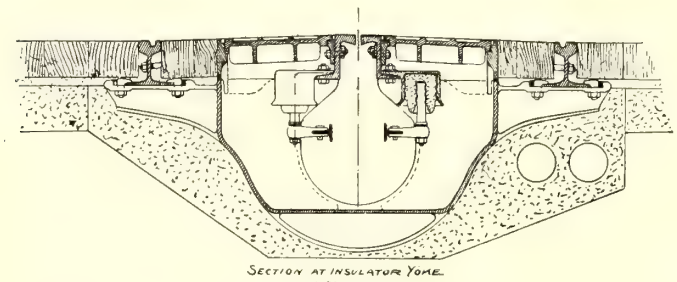
nor for making good the existing Macadam or causeway. All paving stones shall be properly sized before being laid.

Should there be more or less than 20 per cent of new paving stones required for the above work, the same shall be allowed for at the rate stated in the estimate, and the difference in cost added to or deducted from the contract as the case may be.

Grouting—After the paving has been laid and thoroughly beaten all the joints shall be completely grouted and filled, partly with a mixture of best British bitumen and pitch oil, from an approved maker, and partly with granite chips. The bitumen shall be manufactured from pure coal tar pitch, and the oil shall be of 1.035 to 1.050 specific gravity. Sufficient oil shall be used to produce a plastic grout. Each boiler of pitch shall be tested by suddenly cooling a portion of the grout in water, and, after being so cooled, the grout must be plastic and not breakable by bending. All grout must be boiling hot when used. The chips shall be first passed through a ½-in. riddle, then thoroughly kiln-dried, and sand and dust thereafter taken out with ¼-in. riddle, and the chips shall be protected from rain, damp or moisture, until used. In grouting, pitch shall be run into the joints of paving to the depth of 1 in., then one-half of the depth of joint shall be filled with the chips, and pitch run thoroughly into same, and thereafter the remaining depth of joints shall be filled to within half an inch of the surface with chips, and then grouted full with bitumen, but no pitch shall be left on the surface of the paving stones. The chips shall be weighed, and 1 ton shall serve not less than 240 square yards of paving.

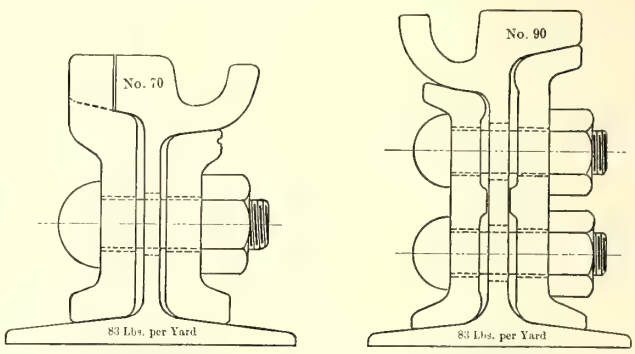
Where cement grouting is required, it shall be composed of one measure of best Portland cement to two measures of *washed sand*, all properly mixed in a tub.

Ducts at Tramways Not Renewed—In the case of the tramways already described as not to be renewed, the contractor will cut a track and insert fire clay pipe or other ducts in the 4-ft. way, or in adjoining street, as may be required, and redress and relay the paving with an assumed average proportion of 20 per cent of new stones with a bed of concrete, all as described for the tramways which are to be reconstructed.



Bonding and Joint Plates of These Tramways—To admit of the corporation bonding these tramways, the contractor to lift so much of the causeway at each joint as may be necessary, these openings being about one-third of a square yard at each joint. These will be afterwards repaved and grouted with bitumen, etc., all as described for the general work. The contractor will also lift a strip of causeway, two stones in breadth, across the full width of the tramway double line, for cross bonding, at every third 45 ft. rail or every second 60 ft. rail. These will be thereafter filled in and grouted as before described. The openings for bonding to be done at such times as the engineer may direct.

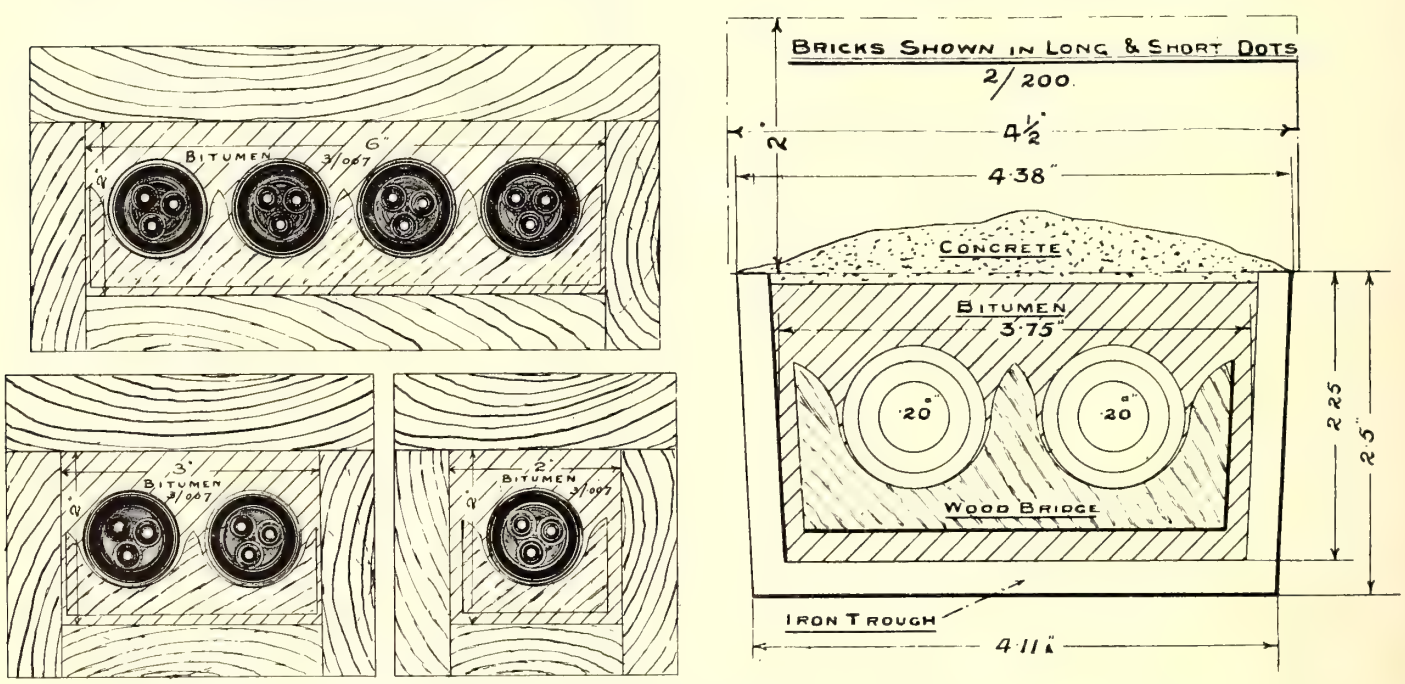
All the joints of 89-lb. rails presently laid shall be fitted with sole joint plates, clips and bolts, similar to sample to be seen at engineer's office. To admit of these being fixed, the contractor shall cut out the concrete from underneath the joints of rails, fix the plates, clips and bolts, and thereafter pack solidly underneath in a thorough manner with fine concrete, as directed. The sole plates, clips and bolts to be supplied free of charge.



The joint plates shall be fixed at the same time as the street is opened for bonding.

Type of Boilers—The boilers for melting the pitch shall be close covered, with provision for leading the gases from the molten pitch to under the fire grate, similar to the boilers at present in use by the tramways department. No other type of pitch boiler will be allowed. The boilers shall be fired with *coke* only. No coal will be allowed.

Railway Works, Gas Pipes, Sewers, Etc.—The contractor shall be careful not to injure or interfere with any railway works, electric lighting works, telephones, gas pipes, water pipes, sewers, underground telegraphs, or appliances connected therewith, which may



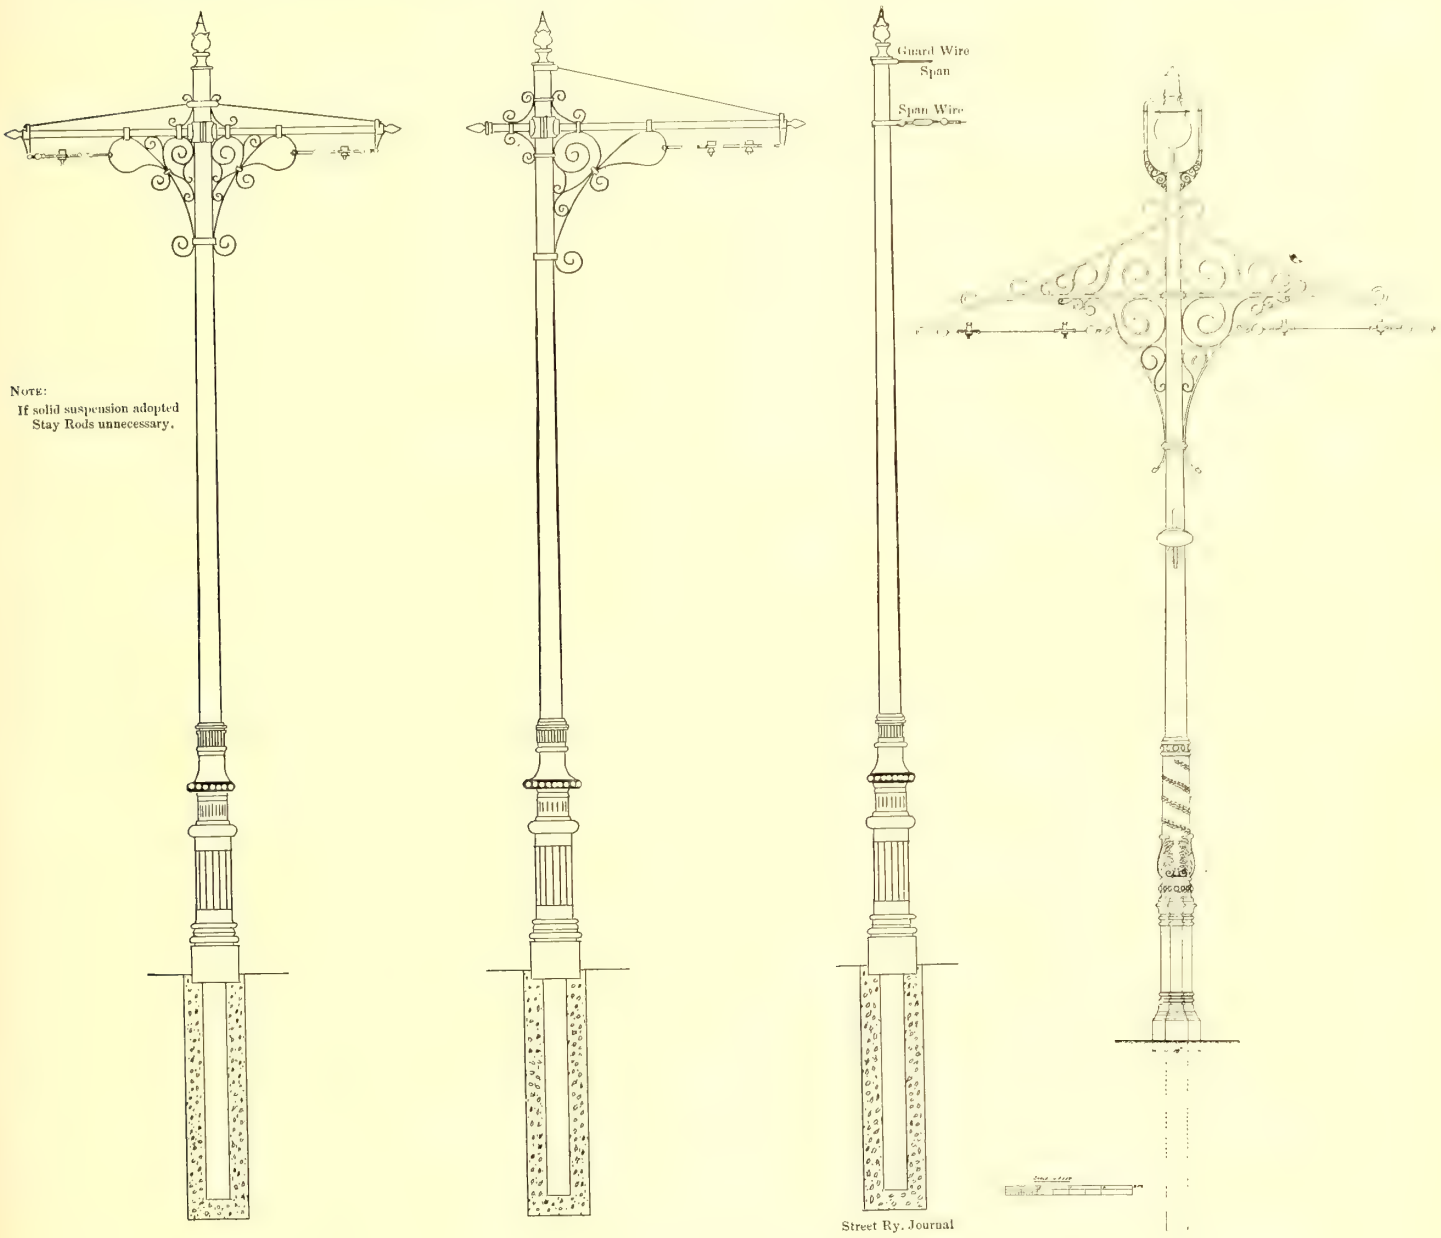
OPEN SLOT CONDUIT CONSTRUCTION, LONDON UNITED TRAMWAYS COMPANY

D.K. New Section D.K. New Section

SOME TYPICAL RAIL SECTIONS

CALLENDER UNDERGROUND CONDUCTOR SYSTEM

be met with on the line of works, and he shall be responsible for and make good all damage, of whatever kind, caused to any of these works by his operations. Should it be necessary to alter or remove any of these works, that shall be done by the respective owners or authorities; but the corporation shall not be in any way responsible for loss, damage or hindrance that may arise to the contractor in consequence of such operations. Such shall be held to be an incident of the contract, and fully covered by the contract price. If the contractor be instructed in writing, he shall remove any sewer, manholes, water or gas stop-cock case, or other works, and reconstruct them, as may be directed, at schedule prices.



Rail Bonding for Electric Traction—The corporation shall provide and fix the bonds, but the contractor for rail laying shall give every reasonable facility to the corporation for carrying out the work of boring the rails, fixing the bonds, etc. This the contractor for rail laying shall do free of cost, the same being held as incidental to the contract, and the corporation will not be liable for any delay, loss or inconvenience to the contractors in this connection.

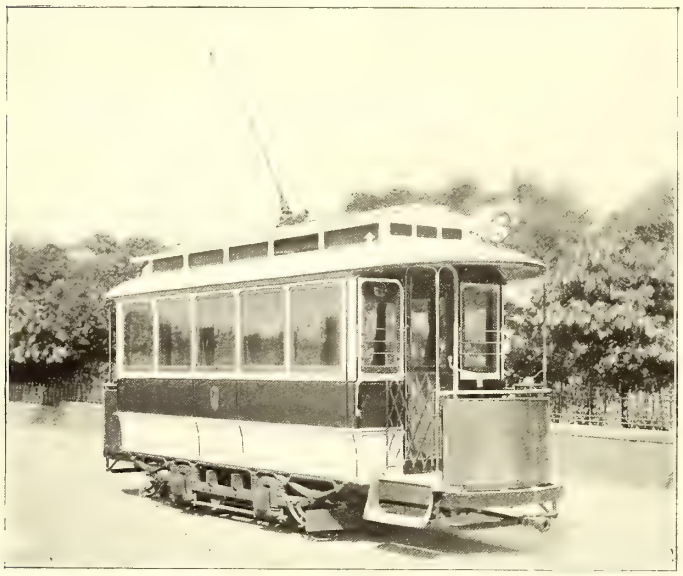
Wood Block Paving—Where wood block paving is interfered with it must be replaced on a bed of concrete and grouted in every respect similar to the existing paving.

The accompanying cross sections illustrate the formation of the completed road-bed, showing concrete, rails and paving stones in place:

The rails in general use are grooved girders, weighing from 83 lbs. to as high as 105 lbs. a yard. The chemical composition is carefully specified by the engineers of the various corporations, and the following is a specimen analysis:

	Per Cent
Carbon	0.55 to 0.65
Manganese	0.80 to 1.00
Phosphorus not to exceed	0.06
Sulphur not to exceed	0.05
Silicon	0.15 to 0.20

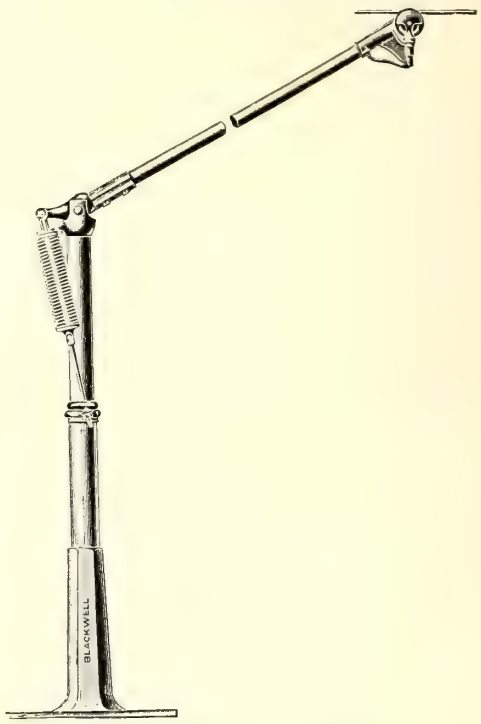
SOME RECENT POLES IN GREAT BRITAIN



These rails are, of course, subjected to very careful physical tests, and the lengths are specified, being in some cases 30 ft. and in others 60 ft., at 60 degs. Fahrenheit.

The accompanying engravings illustrate the types of rail sections, joints, fishplates, etc., used in the standard practice of Great Britain.

There are but one or two instances of the use of cast-welded joints. One of the most popular rail joints in use at the present time is the Dick-Kerr Company's patent joint, in which the fishplate is allowed to come up through the head of the rail quite to its surface, as illustrated in the drawing on opposite page.

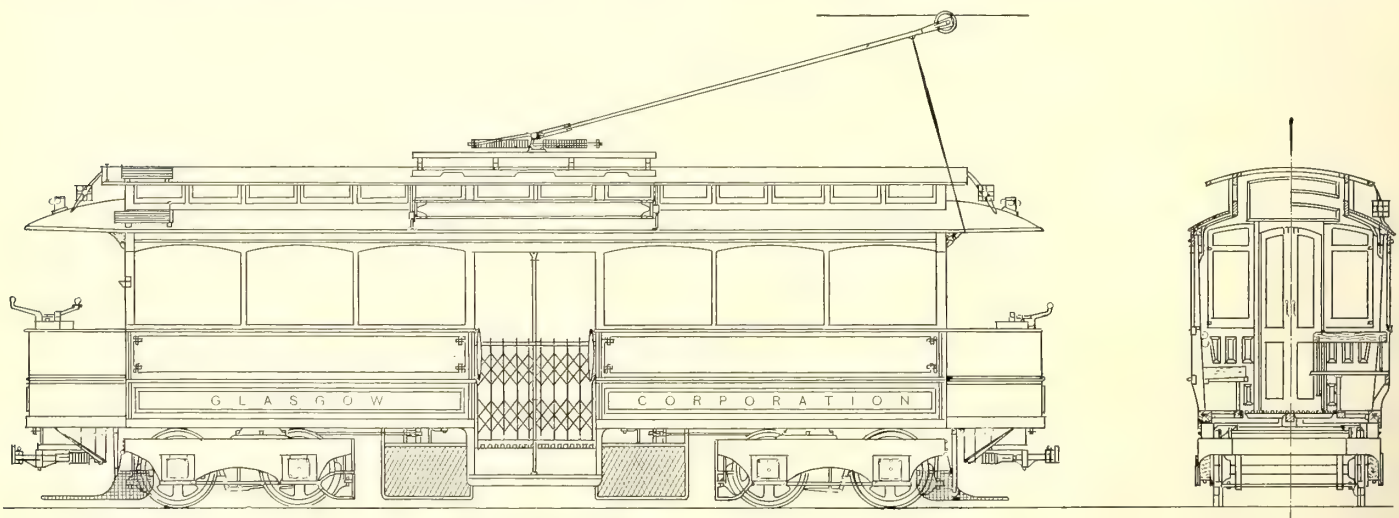


Most of the rails and joints are procured in England or

on the Continent. The Leeds Steel Works, Ltd., is one of the most prominent manufacturers of rails in this country. The special work used in connection with road-bed construction is made either with steel castings, or, in the case of crossings, with built-up sections of the rails. No cast iron special work with special steel points set in is used, except, perhaps, in a few instances where they have been ordered from the Lorain Steel Company. The steel castings for points and crossings are made to present at the street surface the same width as the rail, and the rail itself is of a stipulated width. This, of course, excludes cast iron frogs and crossings. Steel castings and built-up sections are manufactured by English firms almost exclusively.

A MODERN BRITISH CAR BUILT AT PRESTON

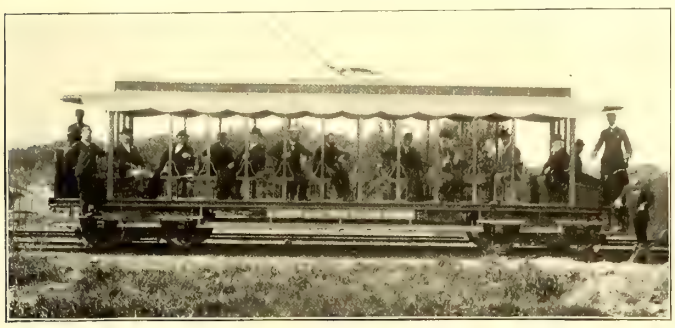
Rails are bonded at the joints by the ordinary copper rail bond. The Chicago bond has been used to a large extent, but recently the Columbia bond, made in America, and the Neptune bond, made in Germany, have come more into favor. The bonding of the rails and the conductivity of the return circuit for electric tramways in England must be of the very best character, owing to a rule established by the Board of Trade, regulating the pressure drop in the return circuit, and also providing for constant tests of this drop, the severest condition being that, when the return is partly or entirely uninsulated, continuous records shall be kept by the company of the difference of potential during the working of the tramway, between the points of the uninsulated return farthest from and nearest to the generating station. If at any time such difference of potential exceeds the limit of 7 volts the company must take immediate steps to reduce it below that limit.



THE DICKINSON TROLLEY

SYSTEMS OF DISTRIBUTION

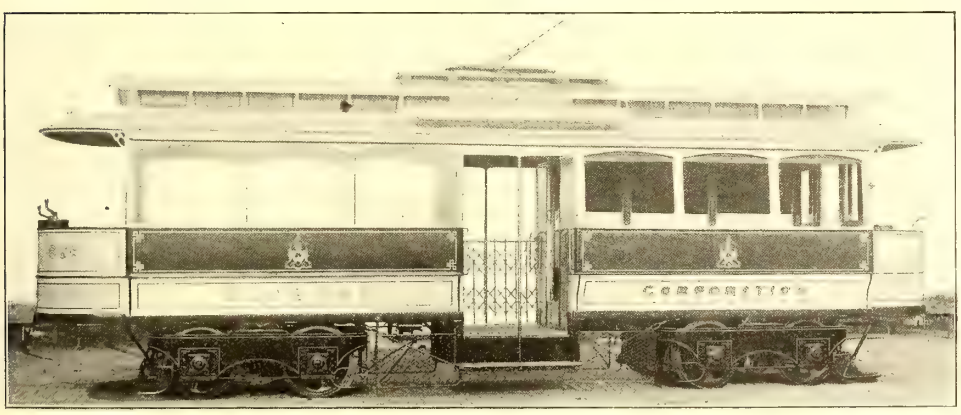
Underground feeders are the rule throughout all the cities of Great Britain. They are carried in conduits of various kinds. The one most used is the "Callender solid bitumen system," as illustrated in the drawings.



Sometimes wooden troughs are used, sometimes iron, and more recently those of terra-cotta are being adopted. The plan is to lay these troughs at the proper depth in the street, and support the cables upon wooden bridges at

SIDE AND END VIEWS, GLASGOW DOUBLE-TRUCK CAR

intervals throughout the length of the troughs, after which the whole trough is filled with bitumen and a tile cover placed on top, whilst the bitumen is still liquid. Another system, which is a drawing-in system, with manholes at regular intervals, known as the Sykes system, and manufactured by the Albion Clay Company, is much like the American. Another drawing-in system is made by the Doulton Company, which is an arrangement of clay tiles with brick or concrete manholes.



Lead covered cables are generally used with the draw-

DOUBLE-TRUCK OPEN CAR, BLACKPOOL & FLEETWOOD RAILWAY

ing-in system, the insulation being paper or rubber. In a few cases armored cables have been laid directly in the ground, the armor being made of steel ribbon, instead of wire.

Trolley wires are supported both by the bracket and by the span wire systems; no wooden poles are used, very ornamental steel poles being the rule. Where the streets are wide, center pole construction with two brackets is preferred, but in narrow streets the iron poles are placed on one side of the street, a short bracket arm carrying the trolley wire. When double tracks are used in narrow streets, where either of these forms of construction would be difficult, the span wire system is used, and sometimes the span wires are attached to the buildings, thus obviating

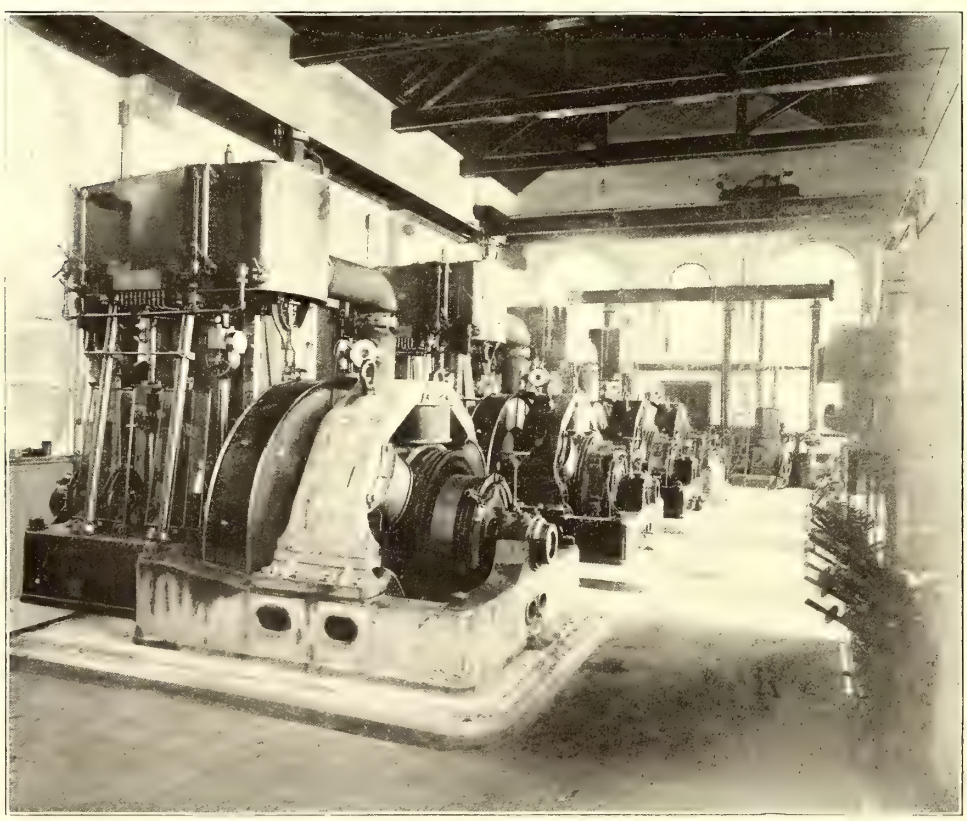
GLASGOW DOUBLE-TRUCK CAR

the necessity for using poles. The trolley wire is always hard drawn copper, from .3 to .4 of an inch in diameter, and is carried on standard American line material or its equivalent. Great care is always taken in the construction of an overhead trolley system, in order that it may be substantial with the least possible obstruction in the streets. The overhead trolley wire does not seem to be objected to by the public in smaller cities and towns, but in London it will not, of course, be permitted. The method of distribution here must be by some form of underground conduit, and undoubtedly the open conduit system will be the one eventually adopted. The London County Council have recently appropriated sufficient money to make experiments on their lines with the open conduit and with the surface contact system. The outcome of these experiments will be exceedingly interesting, the surface contact being a serious competitor to the open conduit sys-

GLASGOW SINGLE TRUCK DOUBLE DECK CAR

tem. The accompanying cuts illustrating the types of poles generally used along the streets, and a photograph of street construction will give an excellent idea of the character of the work which is being done.

CARS, TRUCKS AND CAR EQUIPMENT

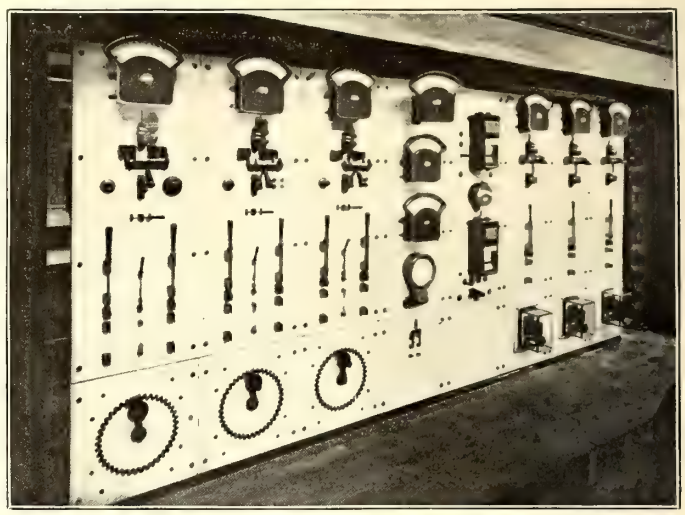


The type of car which has proven most popular and best adapted to tramway work in the British Isles is a top-seat car. These cars are from 25 ft. to 30 ft. over all, with seats running lengthwise inside and crosswise on top.

The reason for the popularity of top-seat cars in England can be readily understood. There are no great changes in temperature and no extreme weather conditions such as are found in the United States. In the midst of winter there are days and parts of days when it is more agreeable to ride out of doors than in a closed car, and even the sudden rains which come up do not drive passengers inside. It is never so cold for long periods of time that it would pay to keep a set of car bodies exclusively for winter use. The open summer car, such as is used in America, is, however, very popular on some of the lines in England during the hot summer months. We find also that a number of corporations are having ordinary single-deck cars built for general use and summer cars in addition. We believe that this practice will grow in favor, or combination summer and winter cars may be adopted.

A number of motor cars have been imported from the United States, but they have been of the cheaper class, and do not represent the best American practice.

Modern motor cars are now being manufactured in England, principally by the Electric Railway & Tramway Carriage Company. This company follows the best American practice, having adapted it to the conditions found here.



The trucks used for electric cars are, in almost every case, imported from America, and manufactured by the Brill or the Peckham Company. Motor equipments are for the most part imported from America, and are of the Walker, Westinghouse or General Electric types. A few motors have been built in England by the Electric Construction Company, the Brush Company and the Siemens Company, and a few German motors, manufactured by the Schukert Electric Company, have been installed at Liverpool. Controllers are uniformly of the series parallel type and are manufactured by the companies furnishing the motors. The trolley device in general use in Great Britain is the "Dickinson," having a swiveled trolley head. These trolleys, stands and poles are manufactured by R. W. Blackwell & Company. Some of the imported equipments have the ordinary standard trolley of the manufacturer. The great advantage of the swiveled overhead trolley is that in narrow streets the trolley wire can be held on very short brackets attached to side poles, and the trolley arm made to reach over it. This is a very simple overhead construction, and less obstructing than the span wire system or the long bracketed poles. On page 670

POWER STATION, BLACKPOOL & FLEETWOOD RAILWAY

is an illustration of the Blackwell trolley arranged for top-seat cars, also one for single-deck cars.

All sorts of brakes are employed on the cars. The authorities require the best known braking device. Air brakes made by the Standard Air Brake Company, electric brake controllers manufactured by the General Electric Company, and track brakes are used, sometimes all on the same car. We believe that the authorities are complicating the car equipment too much; there is less security

SWITCHBOARD, GLASGOW POWER STATION

when safety devices are multiplied than when but one good one is used.

The number of passengers to a car is always restricted by the Board of Trade. It is intended that each passenger shall have a seat either inside of the car or on top, but in most cases passengers are allowed to stand on the rear platform.

Every bill passed by Parliament granting the right to operate electric tramways places in the hands of the Board of Trade the right to fix the rate of speed at which the cars may run. The speed usually allowed is from 6 miles to 8 miles an hour for surface lines, and this is varied at different points on the same road, depending on local conditions. Some of the interurban and suburban lines are, of course, allowed greater speed, but we do not know of any case in which a higher speed than 25 miles an hour is permitted, and this, where in the United States 50 miles an hour would be made. The Board of Trade will undoubtedly gradually sanction higher speeds, when it has been demonstrated that the cars can be properly handled, and that there is no more danger than with the low speeds now in use.

POWER STATIONS

In many cases where the municipal corporation owns the tramways the power stations for the tramway and for the lighting are combined, part of the machines being arranged to operate at the proper pressure for the lighting circuits and part at a pressure of 500 volts to be used for

feeding railway lines. Where the power station is built to serve the tramway alone the general design is similar to those in the United States, so far as general arrangement is concerned, but there is a great variation in the character of the machinery used. So many of the plants for traction purposes are only temporary at present that it is difficult to say what standard design will eventually be adopted.

It is the uniform practice to use direct connected generators. These are coupled to engines of the high-speed type or to the slow-speed Corliss. Where American engineers have been employed to design the power stations slow running engines like the Allis have been adopted, but English engineers have generally specified either a Willans or a Belliss high-speed machine. There is, however, a growing feeling in favor of engines of the slow-speed type, and several large firms in England, who have for many years been building engines of this type, like Musgraves, Cole, Marchant & Morley and others, are going in heavily for electric traction plants. The Willans Company and other of the high-speed English manufacturers are also quite willing to produce engines of large size, running at slow speeds. Until recently the plants which have been installed have been very small, with only a few hundred kilowatts capacity, therefore it was necessary to use small units of from 100 kw. to 400 kw. capacity each. There was good reason for attaching these small dynamos to high-speed engines, and undoubtedly where small units are required this practice will continue. A number of high-speed American engines have been imported. For instance, in the Glasgow temporary plant, McIntosh & Seymour engines running 200 r.p.m. are installed. In all probability England will in the near future produce all the engines which will be required for her electric traction power stations, as there is no doubt about the good workmanship and excellent performance of all classes of engines built here.

The types of boilers vary in different power stations, according to the preference of the engineers who have designed them. Babcock & Wilcox water-tube boilers are installed in several stations, some with automatic stokers and others without, but the Lancashire boiler, which is internally fired, is preferred by English engineers, and they are not usually fitted with automatic stokers, in fact, there is not much to be gained by using stoking devices, as labor is cheap, and the saving, if any, is insignificant. Economizers are used pretty generally, also feed water heaters, and in almost every case the engines are condensing. The piping between the engines and boilers is generally duplicated. We cannot say enough in praise of the excellent steam piping which is done in England. Steel pipes are used with steel flanges threaded and brazed at the joints, and elbows are turned by actually bending or forging the pipe itself.

Where generators are direct connected to very high speed engines a great many bipolar machines are used, but where the speed is lower, multipolar machines are used. Siemens Brothers have furnished a large number of the high-speed generators. Many machines of the slow-speed type have already been turned out by Mather & Platt and by the Electric Construction Company, and many have been imported from America. Part of these are compound wound, running at 500 volts to 550 volts, but those that are used for lighting and power stations combined are shunt wound only. The largest power station in Great Britain now in active operation has just been completed by the Dublin Tramways Company. In this station there is a capacity of about 6000 h.p. from vertical compound Allis engines. Liverpool is about to install a plant of practically the same size, in which Willans engines will be used. The new station for Glasgow will be fully as large, with slow-speed generators.

A GOOD EXAMPLE OF CENTER POLE CONSTRUCTION

The general practice thus far is to operate a system of tramways with one power house only, located as near as possible to the center of distribution. It is difficult to say at present what the economy of these plants will be, as they are as yet in such an unsettled condition. It is evident, however, from the reports of lighting stations, that the present cost per unit of electrical energy is altogether too high. This is accounted for by the use of small units. When larger plants are put in operation the cost for producing electric power will undoubtedly be as low as in the United States.

The Glasgow power station, an illustration of which appears on page 663, shows the usual arrangement of boilers, engines, etc. This station is, however, only a temporary one, and the corporation is about to let contracts for a large station equipped with three-phase apparatus.

The photographs will serve to show the interiors of the engine and boiler rooms. Altogether, electric railway practice in Great Britain is excellent in many respects, and well worthy of careful study, if not of imitation.

THE CHICAGO CONVENTIONS

AMERICAN STREET RAILWAY ASSOCIATION

The eighteenth annual convention of the American Street Railway Association will be held at Tattersall's, Chicago, Oct. 17-20, 1899. The convention will be called to order at 10 A. M. Tuesday, Oct. 17, by President Charles S. Sergeant. The following papers will be presented:

"Maintenance of Car Equipment." J. H. Van Derveer, Brooklyn Heights Railroad Company.

"The Modern Street Railway Shop: Its Design, Machinery and Shop Practice." B. L. Kilgour, electrical engineer, Cincinnati Street Railway Company.

"Train Service and Its Practical Application." Ira A. McCormack, general superintendent, Brooklyn Heights Railroad Company.

"Construction and Maintenance of Railway Track." Edward Butts, Metropolitan Street Railway Company, Kansas City.

"Investments in Street Railways: How Can They Be Made Secure and Remunerative." Charles T. Yerkes, president, Chicago Consolidated Traction Company and Union Elevated Railroad Company, Chicago.

A great deal of thought and care has been given by the committee on entertainment to the social features of the convention, and although dates are not yet fixed, nor has the programme been made public, it is understood that the following will be included among these features:

A reception by the ladies and gentlemen of Chicago prominent in social life to the delegates and ladies in attendance. This will be given in the Auditorium Hotel parlor.

A trip to the drainage canal to inspect the wonderful engineering work going on there.

A trip to the Stock Yards to see Chicago's greatest industry.

A tally-ho ride through the parks and boulevards system of Chicago.

A theater party.

A shopping trip for the ladies to the great stores of Chicago in order that they may understand the conduct of the modern emporiums of trade as shown in Chicago.

The banquet.

In times past there has been some feeling on the part of manufacturers that the convention has not officially paid them sufficient attention and that there should be an adjournment at some time during the convention for the special purpose of allowing the delegates to inspect the exhibits. In deference to this wish the committee on entertainment has fixed the date of the banquet for Friday night, and there will be no session of the convention on Friday, thereby providing the entire day for the inspection of exhibits, and at the same time furnishing a strong inducement to the members to stay over until Saturday. There will also be no entertainments on Friday.

THE STREET RAILWAY ACCOUNTANTS' ASSOCIATION OF AMERICA

The third annual meeting of the Street Railway Accountants' Association of America will also be held at Chicago, Oct. 17-20. As at the last convention the meetings will be held in the same building as those of the American Street Railway Association. The badges of the American Street Railway Association will be furnished the members of the Accountants' Association, and in matters of entertainment and admission to meetings, etc., the same opportunities will be enjoyed.

The papers and reports before this convention are to be as follows:

"Materials and Supplies Accounts." W. M. Barnaby, chief accountant, Brooklyn Heights Railroad Company.

"Car Mileage." H. C. Mackay, comptroller and auditor, Milwaukee Electric Railway & Lighting Company.

"Report of Committee on Standard System of Accounts." C. N. Duffy, chairman.

"Report on Department of Blanks and Forms." W. B. Brockway, secretary of the association.

THE EXHIBITS

The Exhibition Hall is at Tattersalls, on Sixteenth Street and Dearborn Street, about eight or ten minutes' ride from the Auditorium, Victoria, Wellington and other hotels in the down-town district. Either the Wabash Avenue or State Street cars running south can be taken, the latter will probably be found the most convenient. It is exceedingly commodious, as shown by the fact that it has been used in past years as a convention hall by the national political parties when making presidential nominations. The building contains 50,000 sq. ft. of floor space, without a post or obstruction of any kind. A diagram of the building, with the spaces occupied by the different exhibitors, is shown on page 680. The headquarters of the STREET RAILWAY JOURNAL are on the main aisle, directly to the left of the main entrance on Sixteenth Street, and cannot be missed by anybody. The meetings of the two associations will be held on different floors from those devoted to the exhibits, so that noise from the latter will not disturb the delegates.

The following is a list of the exhibitors who have already engaged space:

LIST OF EXHIBITORS AT EIGHTEENTH ANNUAL CONVENTION AMERICAN STREET RAILWAY ASSOCIATION, CHICAGO, 1899

No. of Space.	Exhibitor.	Sq. ft.
1.	C. F. Orr & Company	100
2.	"Street Railway Review"	215

TRANSPORTATION TO CHICAGO

A special rate of a fare and a third will be granted to attendants at the convention, as usual. Persons purchasing tickets will pay full fare going to Chicago, and ask the ticket agent for a certificate, which, when properly countersigned at Chicago, will entitle the holder to a return ticket at one-third fare.

For the benefit of persons going to Chicago from the East, the Committee on Transportation has made arrangements for a special train via the Boston & Albany and New York Central Railroads. This train will leave Boston 10:30 A. M., Sunday, and New York at 1 P. M. the same day. The times of leaving other cities on the route and full details of the train are published elsewhere in this issue.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

We have brought together in this issue a series of papers describing electric railway practice in the four great manufacturing countries of the world, the United States, Great Britain, Germany and Austria, and in a highly civilized "consuming" country, Argentina. The papers on foreign practice are written by engineers and experts in municipal transportation of high reputation and special ability in this field, and their analyses of the work in their own countries are based upon a wide and accurate knowledge of what has been done elsewhere. We should fail to perform our duty did we not attempt to summarize this valuable engineering symposium by setting forth what seem to be the "best things," as well as the differences in engineering methods to be found in the practice of these five countries.

Europe builds its street railway roadbed with heavy masses of concrete as substructure, considering that the desirable end is *rigidity*. The drift of American practice is, however, rather toward *elasticity*. It is certainly necessary with rigid roadbed to adjust car springs most carefully in order to avoid the peculiar jarring effect in the car which is excessively irritating to passengers as well as destructive to rolling stock, but this can, quite as surely, be done if sufficient pains be taken. In defense of the American method it may be said that it is impossible to ride more smoothly and pleasantly at high speeds than on a rock ballasted steam railway roadbed with rails spiked to wooden ties, but this smoothness of running is attained at the cost of close daily attention on the part of a comparatively large force of track men, and such attention as this in paved streets is physically difficult and financially expensive. The disadvantages of a concrete substructure do not come out so clearly with the low speeds common abroad as with high speeds, and there is no question that a more solid and durable construction from a purely engineering standpoint can be obtained with concrete than without.

* * * * *

The depth and weight of rail in each country necessarily varies with the character of paving, but we believe that Europe is using, as a rule, too light a rail for electric traction, and is still using some sections which are a relic of old horse railway practice, and ought to have no place in modern electric railroading at higher speeds. In many of these sections there is no room for a proper size of wheel flange to provide for safety against derailment, the municipal authorities having apparently yielded more to the demands of carriage and wagon traffic than to those of the far greater number who patronize street railways. There are several rail sections in common use in America which are so well adapted to both, that it seems difficult to understand why they are ruled out by European municipalities. The common foreign practice of mortising, and overlapping rail ends so as to form a more nearly continuous rail, is, in the light of American experience, of doubtful value becaus of large first cost and of heavy annual maintenance charges. The rail can hardly help being weakened at the very point where it should be strongest. Our best American joints, including the cast welded, are well able to hold up rail ends to form a continuous surface. It is impossible, of course, to speak positively in general recommendation of details of roadbed practice. At the end of sixty years of steam railroading, engineers still have wide differences of opinion as to roadbed construction, and it can hardly be hoped that all electric railway problems are to be finally settled in a ten years' experience.

* * * * *

To American eyes, foreign street railway cars look heavy, cumbersome and ungraceful, but there is no international artistic standard for judgment on questions of this kind, the American cars perhaps look light and weak to European managers. Wood being far more expensive in Europe than America, iron enters largely into the construction of European car bodies, which perhaps has something to do with their appearance of weight. The best types of cars in each country are certainly good and are possibly best adapted to the character and habits of local

riders. If, for example, a first and second class division of traffic were to be made in America, it would be necessary to radically change the design of our cars. Speed is so urgent a necessity here that in order to obtain it, travelers are denied the many pleasant features of top-seated cars, for there is nothing which will so interfere with maintaining high speed schedules as the long stops necessary for getting up and down the roof stairways. Moreover, the higher the speeds the less is the pleasure of riding on top, particularly in a raw climate, because of both wind and motion. If European riders wish a view of the streets from the tops of cars they must sacrifice time in transit.

* * * * *

We believe it is well within the truth to say that the American electric motor and car controlling apparatus have set the standard for the world. It is inevitable that this should be so, for when the home market is such that a single manufacturing establishment can turn out 25,000 motors of exactly the same type, as has been done in America, special machinery can be built, labor can be subdivided and attention can be given to each detail to the end of producing motors which are more likely to be perfect and interchangeable in their parts than are the few hundred motors called for to satisfy a narrow local market. Nevertheless, German and British manufacturers are now building excellent machines, which are filling not only the home demand, but are going to many foreign countries as well, so that the scale of production has been greatly increased.

* * * * *

European municipalities are far more careful of life than are American, and, as a consequence, they almost universally require safety appliances and air or electric brakes, or their equivalent, upon electric railways. In this respect their example might well be followed by American companies, for there is no question that the common chain brake is too slow of application to suit modern high speed electric railway requirements, and many an accident would be averted if the motorman were given the power of instantly applying brakes by a single turn of a lever, as can be done with air brakes, electric brakes or with some forms of mechanical brake. It is the emergency stop, however rarely put in practice, which saves a heavy bill for damages amounting often to the entire cost of the equipment of a road with improved braking apparatus, to say nothing of the relief to the manager's conscience in not having the blood of a fellow-being on his head.

* * * * *

American electric railway power stations are using much larger units on an average and as a maximum than are European stations, which still regard a 500-kw. generator as large, whereas 1500-kw., 2000-kw. and 3000-kw. machines may now be regarded as common American practice for stations in the larger cities. Here, again, European practice in this respect is justified in most cases, on the theory of "small beginnings" in electric railroading, which have made necessary the adoption of small power station units. The larger sizes will quite surely be used as the stations grow. Water tube boilers and station auxiliary devices of all kinds are of much the same types in all countries, as the engineering principles in the design of steam plant are the common property of all manufacturing nations.

Overhead electric construction in Europe is probably superior to that in America, judged from the standpoint of the artist and of the engineer, for great pains have been taken, particularly in Germany, to produce highly ornamental designs for poles, rosettes, etc. Nevertheless, there is much to be said in favor of the simpler pole designs, which are usually less conspicuous in the street than are the more ornamental ones, but it cannot be denied that many American street railway companies have erred in imposing wooden poles, feed-wires and other eyesores upon the public in the smaller cities. In line material, America has again set the standard of the world, chiefly, of course, because it was here that commercial electric railroading was first developed.

* * * * *

Germany has been quite successful in adapting storage batteries to the propulsion of electric cars on what is known as the "mixed system," by which means overhead wires have been avoided in the business district. The batteries are charged from a line in the suburbs and carry the car to the city termini without direct current supply. How costly this combined service is we do not know, but it would be difficult to apply it in America for the reason that our street railway lines stretch far into the country and the storage batteries would often have to be carried as dead weight for 90 per cent or more of a round trip in order to work for 10 per cent or less. This would be not only costly in power consumption, but in car and track depreciation as well, while the storage batteries themselves, always a source of expense for maintenance, would add still further to the operating cost of the mixed system in America.

* * * * *

European practice is distinctively more conservative than American in the matter of insisting upon small losses in both outgoing and ground return circuits, particularly the latter. The regulations of the British Board of Trade permit a drop of but seven volts in the ground circuits, seeking thus to prevent electrolysis, and in the best engineering practice this drop is even lower than that called for by the Board of Trade, negative boosters being often used to bring this about.

* * * * *

The policy of American municipalities has always been and is now that of permitting private capital to handle its street railway enterprises. This is true to nearly the same extent also in Germany and in Austria, though latterly there has come into vogue in these countries a plan of municipal ownership of roadbed and private ownership of equipment, which is working to the apparent satisfaction of all concerned. In Great Britain the tendency is very strong toward municipalization of all public service enterprises, and private capital finds it almost impossible to obtain a foothold in tramway development, though still permitted to take some part in the building of "light railway," or interurban lines. Without attempting in this place to comment on the wisdom of this decision, it may be said that it is quite certain to be persisted in to the end, and that ten or fifteen years hence practically all municipal service enterprises of this kind will be owned and operated by the public. As a consequence, tramway development in the British Isles will follow with lagging steps and to a limited extent only, that of Germany and the United States, as has been the case during the past ten years.

FINANCIAL CHARACTERISTICS OF THE LARGE CITY TRANSPORTATION SYSTEMS OF THE WORLD

BY EDWARD E. HIGGINS

In dealing with financial statistics of any kind in different countries, it is usually impossible to make true comparisons and to reduce their varying financial practice to a common basis except upon simple and clearly defined lines, and even when these lines are chosen it is often difficult to present figures which do not involve some anomalies.

I must first, therefore, explain and criticise the accompanying table, which represents the results of careful, but not wholly satisfactory investigation of the financial characteristics and traffic figures of the more or less complete city transportation systems of thirty cities and population centers of the world, of 500,000 inhabitants or more. As there are but thirty-eight of such population centers in all, this presentation is reasonably complete.

The key to the arrangement of a table of this kind lies in the "population served." All things being equal, the million people of one locality require approximately the same transportation facilities as do the million people of another, and if their traffic returns show that they do not obtain or use them, it is the business of the promoter and the capitalist to supply the deficiency, or at all events, to find out why the small traffic city does not come up to the standard of the large. In this table, therefore, the cities are arranged in the order of their populations, the largest first.

As it often happens that city railway systems reach out into independent suburban townships and cities, it is necessary in order to get satisfactory results to find the smallest area which can be isolated from surrounding territory, to get the population of this area, and to combine the reports of all the street railway companies operating therein. In Paris, for example, there must be added to the population of the city proper that of fifteen or twenty suburban towns which can be reached from the heart of Paris by horse, electric or steam railways. For this reason, the population figures given in the accompanying table often seem large. The most recent reliable figures are taken in all cases, those given in the Statesman's Year Book of 1899 being, as a rule, accepted where no figures known to be better are found.

"Miles of track" means total mileage, single track basis (counting 1 mile of double track as 2 miles of single), with switches, sidings, etc. It is upon this figure that the capitalization is properly based, but a better standard for gross receipts would be "miles of road," i. e., miles of streets through which railways are laid, since traffic density measured by gross receipts is dependent upon road mileage rather than upon track. It is, however, almost impossible to get reliable figures of road mileage in all cases.

"Capitalization," as used in the accompanying table, represents, as a rule, the sum total of the capital stock (German, *aktien-capital*, French, *actions*), and the funded debt (German, "obligationen-capital," French, "obligations"), of all the companies in the population area. Were it possible to do so, it would be desirable to obtain the true cash investment in these properties as a basis of determining the percentage return of profits, but in hardly an instance could this be done with any approach to reliability. In the case of French and German companies, the capitalization account as it stands upon the books at present, is often considerably less than the original capitalization owing to the operation of amortization funds.

The attempt has been made to include in the figures of "capitalization" only the stocks and evidences of funded debt actually afloat in the hands of the public, excluding therefrom treasury securities in the form both of unissued capital liabilities and of stocks of controlled companies held in the treasury of the controlling ones. In some cases, however, it has been impossible to do this, notably in New York, where a large or controlling interest in certain companies has been purchased by others. Part of these purchases are represented by floating debt, part may at any time be sold to provide cash for the controlling company, and in Brooklyn, the combined elevated and surface systems have been welded together in such a way that the capitalization shown in the table is not greatly different from that actually outstanding in the hands of the public at the present time. It has also in this case been necessary to estimate the capitalization on the mileage of one street railway line which is the city branch of a large steam railroad system, and has no separate capitalization account.

"Capitalization per capita" is useful from two exactly opposite points of view. Wherever the capitalization per capita is extremely small, it shows that the facilities are inadequate and that there ought to be a chance for a further large investment of capital. Such a case as this is found in the tramway systems of London and Paris, and indeed nearly all of the cities outside of the United States. In cases where the capitalization per capita is extremely large, it indicates, as a rule, heavily watered securities. Taken in connection with the gross receipts per capita, some indication is given as to whether or not a capitalization can be supported, since from 40 per cent to 50 per cent of the gross receipts per capita can usually be depended upon as a return on the capitalization per capita. Of course, it must not be forgotten that a large proportion of the capitalization is in capital stock upon which a return is not obligatory, so that even an excessively overcapitalized company may still be perfectly solvent as far as ability to meet its obligations is concerned.

"Gross receipts" means in practically every case receipts from operation only, including those from passengers, freight, baggage or express matter, car advertising, sales of by products, etc., but not interest on current balances or income other than that arising from operation.

In "net profits," however, account is taken of these miscellaneous sources of income other than from operation, the object being to show the amount of earnings, in the year for which the report is made, actually applicable to the payment of interest on funded debt and dividends on stock.

For the street railway manager, the most valuable col-

umns in the table are those headed "passengers carried per capita" and "gross receipts per mile track—per mile run and—per capita." For the promotor and capitalist, the most valuable columns are "passengers carried per capita," "capitalization per capita," "gross receipts per mile of track and—per capita," and "percentage operating profits to capitalization."

Passing now from the mere mechanism of the table as described above, it will be interesting to point out some of the peculiarities of the different city systems, and to comment upon the opportunities for development which are found therein.

In no large city of the world are the transportation facilities so utterly disproportionate to the requirements as is the case in London. It is, of course, true that in a city of such enormous size, both in area and in population, a railroad suburban train service must and will be relied upon always for considerable distances from the city proper to the suburbs, and there is no question that the suburban service of London is a magnificent one in many respects; but it is almost equally important that the people should be quickly transported for short distances in carrying on their daily work, and it is here that the city transportation system of London fails so completely. Great lumbering omnibuses amble slowly through the streets, taking up an altogether disproportionate amount of street room for the facilities which they give, and it is well within limits to assert that were they all removed bodily from London streets and their place taken by long electric cars, even in such business thoroughfares as Fleet Street and the Strand, the total street capacity and the possible movement of population would be trebled at least, while the physical congestion in the streets would be greatly lessened through the regulating power of the cars in compelling wagons, carriages, etc., to take their proper sides. We may speak on this point with emphasis and conviction, because under exactly similar conditions we "straightened out" Broadway in New York City some fifteen years ago, by building a street railway (originally a horse line) right through that busy thoroughfare, until then congested to the point of suffocation by a combined omnibus and wagon traffic which had become wholly unmanageable. To-day, cable cars pass down this narrow (therefore misnamed) street, at twenty seconds intervals in the busiest hours of the day, and millions upon millions of people are carried upon them who would never in the world have found accommodations under the old regime. Few single acts of public policy have ever been so fully justified by results as the building of the Broadway railway, in spite of the scandals which attended its inception.

It is amazing to find in London but 242 miles of street railway track, an investment of but $3.50 per capita therein, and a gross earning power of but $1.27 per capita. Compare these figures with the corresponding ones for Greater New York, with its 1027 miles of surface railways, capitalized at $58.34 per capita and earning $7.46 per capita. It cannot be objected that this higher earning power in New York is due to the larger fares charged, for, curiously enough, the receipts per mile run are almost exactly the same in the two cities, while the densities of traffic, as shown by the gross receipts per mile of track, are nearly the same, those of London being slightly the larger. Moreover, the fares, based on average distance traveled by passengers, are undoubtedly smaller in New York than in London.

It may be noted in passing as an interesting fact, that the omnibus lines of London are earning nearly as much net profit as are the tramway lines, although the investment account of the omnibus companies is less than one-half that of the tramway companies. These omnibus profits are equal to 9.7 per cent upon the investment as against but 5.5 per cent with the tramways.

The present underground railways of London are enormously costly and their earning power unsatisfactory, being but 2.6 per cent upon the capitalization. The reason for this lies partly in the fact that the principal underground railway is a belt line, which skirts the true business district of the city so that it is somewhat out of the way for much of the travel which is seeking accommodation, while at the same time, it is so extremely disagreeable to travelers on account of the smoke and gas escaping from locomotives, that an immense number of people prefer to pay far more for cab hire or to spend more time on omnibuses than to inhale the bad atmosphere of the tunnels and cuts. The adoption of electricity would doubtless greatly increase the travel on this line, and it is almost inevitable that this step will be taken in the near future. Some experiments have, in fact, been made in this direction.

Greater New York is rapidly completing what will soon be the most perfect and highly developed municipal transportation system in the world. At present its elevated railways are run chiefly by steam, but the decision has been made to convert them to electricity; its surface railways are run in part by the cable system, which will soon, however, disappear from all its lines; in part by the underground conduit electric system, which will shortly be the almost universal system in use on Manhattan Island; in part by the overhead wire electric system, in use in the boroughs of Brooklyn, Richmond, Queens and the Bronx; while there are yet more than 100 miles of track where horse cars are to give way to electricity or compressed air, with which latter power some experiments are now being made with the possibility of adoption on the crosstown feeder lines of Manhattan. Until the past two or three years, the elevated lines have been the only ones where real rapid transit could be obtained, and their earnings were therefore on an increasing ratio from year to year. With the adoption of electricity on the surface lines, however, the gross and net earnings of the elevated roads have turned downward and are now less than for many years past, while those of the surface lines show a more than corresponding increase.

In the table are shown the financial and traffic statistics of the street railways, the elevated railways and the entire transportation system (*a*) of New York City as a whole, (*b*) of the boroughs of Manhattan and the Bronx, and (*c*) of the boroughs of Brooklyn and Queens. The entire system of Greater New York is earning $10.76 per capita, of which $3.31 only is taken by the elevated railways in the boroughs of Manhattan, and the Bronx, and Brooklyn, while $7.46 per capita is taken by the surface railways. The latter are earning 5 per cent upon their capitalization, while the elevated railways are earning but 3.2 per cent upon theirs. The transportation system as a whole is carrying 744,614,000 passengers as against 685,411,000 in London.

Paris, the third largest city in the world, still clings to omnibuses, no less than 139,000,000 passengers having

tion of the Brooklyn system as represented by securities in the hands of the public is somewhat larger than figures given herewith, which represent original capitalization.

8. This figure represents "investment," not capitalization proper.

9. This figure represents percentage on "investment," not capitalization.

10. Report of one company is for year ending March 31, 1898.

11. After deducting taxes.

12. One company's report covers ten months only.

13. Including lines owned by Corporations of Manchester, Salford and Moss Side, operated by Manchester Carriage & Tramway Company.

14. Excluding figures of St. Louis & Suburban Railroad Company, which has a mileage of 28.5 and gross receipts of about $600,000 per annum.

15. Including all St. Louis companies.

been carried by this means in 1898. These omnibuses are actually earning $0.355 per mile run, an extremely large figure even for street railways, while $1.68 per capita is the measure of their gross earnings. The 230 miles of street railways in Paris and suburbs, many of which are steam and but few electric, are earning $2.26 per capita and 4.3 per cent upon the capitalization, the percentage of operating expenses to gross receipts being 85.4. What an immense opportunity exists here for the introduction of electric railways, a consequent reduction of the operating expenses per passenger, to between 50 per cent and 60 per cent of the gross receipts, and a heavy increase in profits!

Elsewhere in this issue will be found a map clearly showing the street railway and elevated railway systems of Chicago, together with a more or less complete description of their engineering and financial features. Taken as a whole, the entire transportation system (reporting) is carrying the city's population 167 times per annum, and is earning $8.50 per capita gross, while the return upon the relative investment accounts is 6.3 per cent for the street railways as a whole (five principal companies), and 1.9 per cent on the elevated railways.

The two German cities in the table, Berlin and Hamburg, are earning $2.88 and $2.98 per capita respectively, on a capitalization of $9.25 and $11.16 per capita. Berlin is carrying its population 107 times per annum. These are excellent examples of well managed and successful German properties. The two Berlin companies, reporting, earned 12.6 per cent on their capitalization, and the Hamburg company 9.5 per cent. Nevertheless, the traffic figures seem small as compared with the corresponding figures of Chicago, which is nearest the size of Berlin, and of St. Louis or Baltimore, which are nearest the size of Hamburg.

Much the same reports come from the Austrian city of Vienna, but Hungarian Budapest verifies its reputation for Western progressiveness by showing an earning power of $5.09 per capita, and $44,862 per mile of track, while its capitalization account reaches the respectable figure of nearly $30 per capita. In this case the twin cities of Pittsburgh and Allegheny and of Cleveland with suburbs, are the cities nearest Budapest in size, and both have larger receipts per capita.

One city only in the entire list can boast of having no street railway service whatever, and that is Osaka, Japan. That this is not from profit earning possibilities is shown by the results of a little 25-mile tramway in Tokyo, which earned in 1897-8 about $256,065 gross on a capitalization of only $375,000 (gold), while the net earning power (not given in the table) was equal to more than 35 per cent upon the capitalization. Dividends to this amount were declared, and the dividends for several years past have been on an almost equally large scale. The entire gross receipts amount to but $0.21 per capita, and it would seem as if there ought to be no difficulty in persuading capital to undertake tramway construction in Japan under existing conditions, provided only that concessions can be obtained.

Aside from London, there are three English cities and one Scotch, exceeding the 500,000 population limit, Manchester, Birmingham, Liverpool and Glasgow. The systems of these cities are carrying their population 62, 70, 61, and 135 times per annum respectively, and are earning $2.63, $1.94, $2.39, and $2.51 per capita respectively. These are all low figures, showing great possibilities of development, and this feature is especially brought out also by the figures of capitalization per capita, which amount is but $3.84 for Manchester, $5.08 for Glasgow, $7 for Birmingham and $12.29 for Liverpool.

It would seem as if there should be an opportunity for further tramway development in Calcutta, India, whose 19-mile system is at present earning but $0.39 per capita gross on an investment of but $2.10 per capita.

In the city of Buenos Ayres, Argentina, a city nearly every street of which is occupied by railways, the gross receipts per capita of five of the companies amount to $5.52, and per mile of track $44,273. These five companies are carrying the population of Buenos Ayres 120 times per annum.

Lyons, a commercial and manufacturing company of considerable importance in France, is earning $2.94 per capita for city and suburban lines, and 5.7 per cent on a capitalization of $18.98 per capita.

Finally, it is evident from the table that in the American cities with population centers of 500,000 inhabitants or more, street railroading is carried to a far higher degree of development as tested by public patronage than is the case abroad. Arranged in the order of traffic secured per capita, including all kinds of transportation systems within city limits, American cities stand as follows:

	Passengers carried per capita	Gross receipts per capita
New York (Boroughs of Manhattan and the Bronx)	234	$11.92
Boston	230	11.76
Greater New York	210	10.76
Philadelphia	202	9.35
Pittsburgh-Allegheny	184	8.71
St. Louis	172	
New York (Boroughs of Brooklyn and Queens)	172	8.69
Chicago	167	8.50
Baltimore (approximate)	130	6.62

The leading foreign cities appear in the following order based on gross receipts per capita:

	Passengers carried per capita	Gross receipts per capita
Buenos Ayres	120	$5.52
Budapest		5.09
London	124	4.32
Paris		3.94
Hamburg		2.98
Berlin	107	2.88
Manchester	62	2.63
Glasgow	135	2.51
Liverpool	61	2.39
Vienna		2.14
Birmingham	70	1.94
Brussels	68	1.93

One curious fact may be noted in this table. In spite of what are generally, though to some extent mistakenly, supposed to be lower fares in foreign countries as compared with the American five-cent fare, the gross receipts per car mile abroad are quite as high as they are in this country, which would seem to indicate either a better average travel throughout the day, a much shorter distance run per passenger, or overcrowding of cars. The latter cause is not the principal one, at least, and we believe that the average passenger in America rides considerably longer distances for his five-cent fare than is generally thought to be the case.

ELECTRIC RAILWAY PRACTICE IN AUSTRIA-HUNGARY

By E. A. ZIFFER

The first electric railway in Austria was for passenger service, and was built for the K. K. priv. Südbahn Gesellschaft by the Siemens-Halske Company, of Berlin. It extended from Mödling to Vorderbrühl, a distance of about 4 km. It was opened Oct. 22, 1883, and the system employed was the overhead, with split tube conductors, a method now antiquated and out of use.

The first electric railway in Hungary was opened to public traffic on July 3, 1889. It was 2.52 km. long, and was the first conduit system with slot rails to be so practically successful as to be continued in service. This same system, though with various improvements, was applied in 1879 to more than 31 miles of track. It is illustrated on page 687. The same system is also employed on the Ringstrasse line and elsewhere in Vienna.

Electric railway construction, so auspiciously begun ten years ago, made, for a long time, but little progress, as the authorities in the various towns resolutely opposed the installation of the trolley system. While the arguments advanced for this course were in some cases valid, pure business reasons and policy made them partial toward other systems at various times. It has been only during the last few years that expert opinion in this empire has leaned manifestly toward the introduction of the overhead system, which has shown marked advantages over all others in efficiency, reliability and low first cost. The fears expressed of this system in its early days have not been realized, so that now companies operating with animal power in Vienna, Buda-Pest, Prague, Graz, Brünn and Trieste have decided on the substitution of the trolley. The permission of the authorities has been secured, portions of the lines in these cities are already partially equipped and the rest is now in course of construction.

In Austria the electric railways are owned, not only by private companies, but also, in many cases, by electrical manufacturing concerns, as well as financial institutions. In addition, the municipalities have recently interested themselves to a considerable extent in the construction of new, and re-equipment of old lines.

This has been the case in Vienna, Prague, Lemberg, Brünn, Czernowitz and Olnmetz. These municipalities either manage the systems themselves or lease them, as is the case in Vienna, to private companies. The initial ownership of all franchises, however, is vested in the State, to whom all applications have to be made. By authority of a statute passed Dec. 31, 1894, the State authorities may grant concessions to either municipalities, for roads within their jurisdiction, or to private individuals or corporations. The life of the former is limited to ninety years and the latter to sixty years, but the State has the right to resign the right of ownership in case of municipalities, while railroads owned by private corporations become the property of the government or the State at the end of the franchises. The present mileage of the independent railway enterprises, compared with the municipal ones, is as two to one in Austria, and in Hungary, where this law is not in force, as four to one.

TYPICAL PASSENGER STATION ON THE GUNTRAMSDORF-BADEN ELECTRIC RAILWAY (VIENNA LOCAL RAILWAY)

The following firms are those which have principally been identified with the construction of electrical plants in Austria: Siemens-Halske, the Oesterr. Schuckert Works, the Vereinigte Elektricitäts-Actien-Gesellschaft (formerly B. Egger), the Elektricitäts-Gesellschaft, Felix Singer & Company, the Allgemeine Elektricitäts Gesellschaft, the International Elektricitäts Gesellschaft, and General Repräsentanz of the Continental Gesellschaft for electrical enterprises, all of Vienna; and the electro-technical establishment of Fr. Krizik in Prague. Accumulators are supplied by Wüste & Rupprecht in Baden, near Vienna,

the Accumulatoren-Werke, the Pollak works in Liesing, near Vienna; Böse & Company, in Vienna; Burger, in Vienna, and Deckert & Homolka, also in Vienna.

All railroads of secondary importance are free from State taxes in Austria for a period of twenty years, and at times are also free from city taxation. Frequently, however, private railroad enterprises have to pay considerable sums to the community, and also have to undertake other duties. The same rights and privileges also hold where communities obtain franchises themselves, a matter which was described by the writer in the STREET RAILWAY JOURNAL (International Edition) last December, in connection with the operation of the street railway company in Vienna, which is under obligations to build over 150 miles of track. As a rule the community imposes on the railroad companies certain conditions for operation, to which the latter have to submit, in conjunction with the rules laid down by the railroad commissioners. The gross and net incomes of all railroads are published weekly or monthly in the local papers in Austria-Hungary, and must be submitted by the companies in a form satisfactory to the government; moreover, complete statistics must be given of the condition of the property, etc., with all annual reports of the board of directors, to the stockholders and to the government. The latter also has a delegate to inspect the reports and be present at the meetings of the boards and at the general meetings of the stockholders. The government and the municipalities usually agree on the determination of the dividends and over-capitalization in the construction of new railroad lines is not likely to occur.

The older electric railroad companies in Austria-Hungary are generally prosperous, and divide annually dividends up to 10 per cent. Gross, as well as net, earings are constantly growing. The status of the electric railways in Austria-Hungary, Bosnia and Herzegowina up to the end of June, 1899, is found in the following table:

A.—AUSTRIA	Average Length in Kilometers.	Gage in Meters.	Passengers Carried.	Increase in Florins.
1 Baden-Vöslau	8.03	1.435	193,962	19 656

(1.) Also carry freight, the income for which was 24,087 fl.
(2.) Of the total 5.309 km. are operated on an accumulator system.

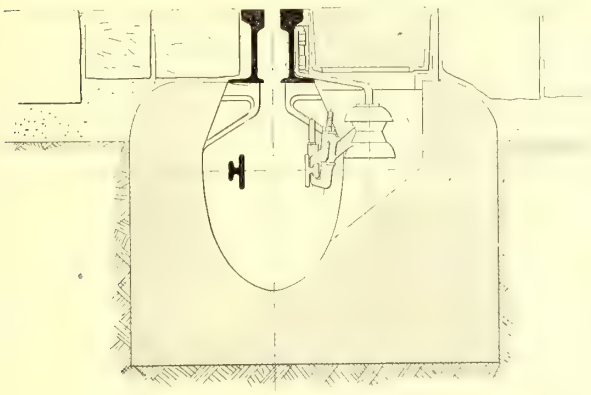
REMARKS TO THE PRECEDING TABLES

To this total length of 240.35 km. has to be added the horse car line in Graz whose electric operation was commenced on July 24 of this year. The re-equipped, standard gage, double track railway has a total length of 12 km. and the Grazer Tramway Company is under obligation to build about 25 km. of track within the city and the suburbs.

On July 1, 1899, the following standard gage roads were in course of construction:

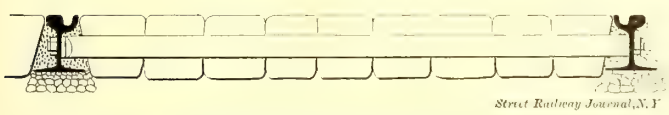
1. Branch to Traiskirchen of the Guntramsdorf-Baden Road, 2.3 km. The main road was opened May 10, 1899.
2. Belt line in Baden, 2.287 km. Opened Aug. 30, 1899.
3. Smirchow, with central station, 6.445 km.
4. The existing horse roads in Vienna, Brünn, Trieste and Prague are being transformed into electric roads.

In general, it should be added that no standard method of construction or installation exists; that local conditions, as well as the wishes of the companies, govern greatly the method pursued; that, furthermore, the conditions imposed by the city and State government are to be observed, and that their approval of all methods of construction and installations must be obtained. Finally, there are the patents for the machinery and supplies owned by the large electrical manufacturing concerns, who, in many cases, undertake the construction of the railways, and this makes the different roads vary widely in character. On account of the conditions mentioned, it is well to describe here the principal types and methods of construction.



TRACK CONSTRUCTION

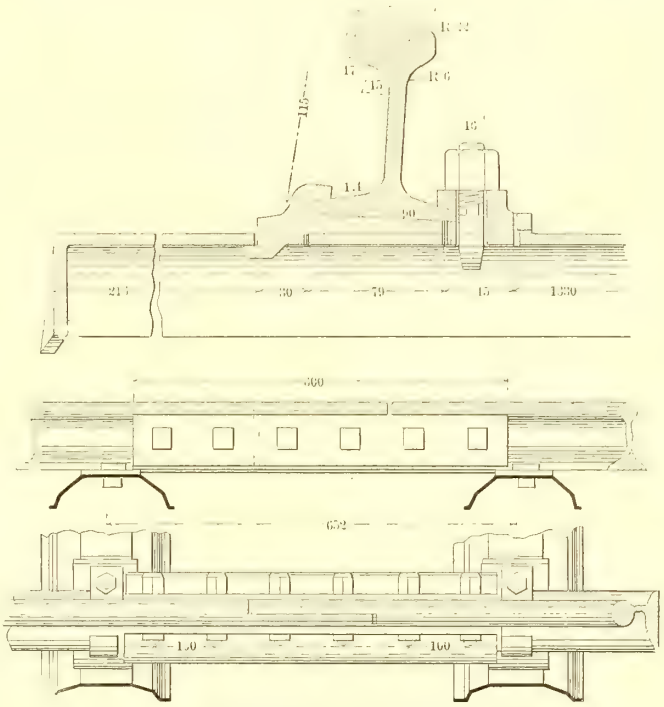
The rails in city streets are laid either on a foundation of concrete or on a broken stone or gravel bed of about 30 cm. thickness. The street surface on paved streets is generally paved between the rails and ½ meter to 1 meter on the outside of the tracks with stone blocks or silicified wood. This paving is usually done by the street railway company or at its expense. Where the streets are asphalted stone sets are usually laid along side the rails. On suburban roads the rails are frequently laid on 25 cm. to 30 cm. of concrete. No standard rules are followed in this method of construction, except that special methods are sometimes specified by the authorities granting the concessions.



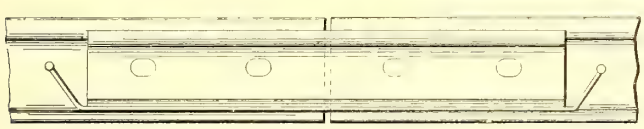
The rails for city service, especially in paved streets, are usually of the grooved type, made of Bessemer or Martin steel, are 12 meters long and weighing from 34 kg. to 43 kg. per meter. Tie rods of angle iron and fastened by bolts and nuts, are usually used every 2.5 meters. Under these conditions the track weighs from 74 kg. to 96 kg. per meter.

Besides the grooved rails, the Haarmann twin rail (155 mm. high), as well as the Demerbe rail, is used on short stretches. Above is shown the cross-section of a standard gage track, as well as several rail sections in general service. On the electric section of the Ringstrasse-Prater Road in Vienna grooved rails, 41 kg. per meter, are used, with points connected by wedge-shaped plates, which are driven home and held with spikes. On the Buda-Pest Franz Josef underground electric road the rails are 9 m. long, 115 mm. high, weigh 24.2 kg. per meter, and are laid on ties .928 m. apart. The joints are of the Haarmann grooved plate type, held with one bolt, and are laid on a concrete bed.

In the electric conduit road in Buda-Pest slot rails form one service rail, the other being of the ordinary type. The slot is 35 mm. wide. Further particulars of this construction were given in the STREET RAILWAY JOURNAL for July, 1897.

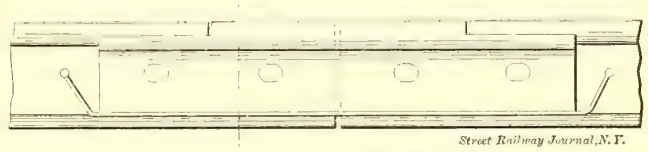


SECTION OF CONDUIT—BUDA-PEST

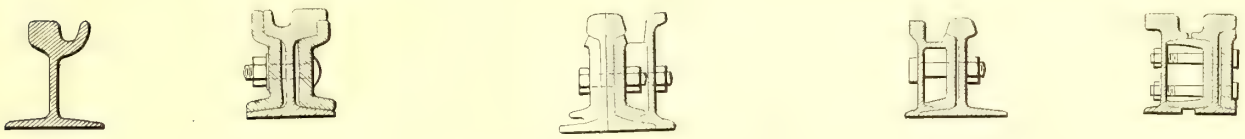


STANDARD TRACK CONSTRUCTION FOR TRAMWAYS

Outside of the city limits proper and in the suburbs, Vignole, or T rails, weighing from 21 kg. to 23.5 kg. per meter, are generally used. These are usually mounted on wooden ties, or, as is the case on the Pöstlingbergbahn, have wedge-shaped bases which fit into tie plates. This construction was described in the STREET RAILWAY JOURNAL (International Edition) for January, 1899. Rails are usually obtained from the Oesterreichische Alpine Montan-Gesellschaft, the Phœnix Actien Gesellschaft at Rührort, or the Hörder Bergswerks-und Hüttenverein in Hörde. The railway company is usually allowed to select its own rail section, but its choice is subject to the approval of the authorities. Switches, crossings and other special work are furnished in Austria by the ironworks Wittkowitz, Teschen, Zeltweg, Teplitz, etc., and in Hungary, by Ganz & Company, and are of chilled iron or cast steel, principally the latter. Made up special work is also used.



The rail bonds are usually copper strips (so called, Union bonds) of 107 sq. mm. cross-section, and connected to the rails by galvanized iron rivets, though in some cases continuous copper bonds are used. For a description of the bonds of the Ring-Prater line in Vienna, the



TRACK CONSTRUCTION OF FRANZ JOSEF UNDERGROUND RAILWAY—BUDA-PEST

Side elevation of renewable head joint

Phœnix (No. 7) rails

Section at joint of renewable rail

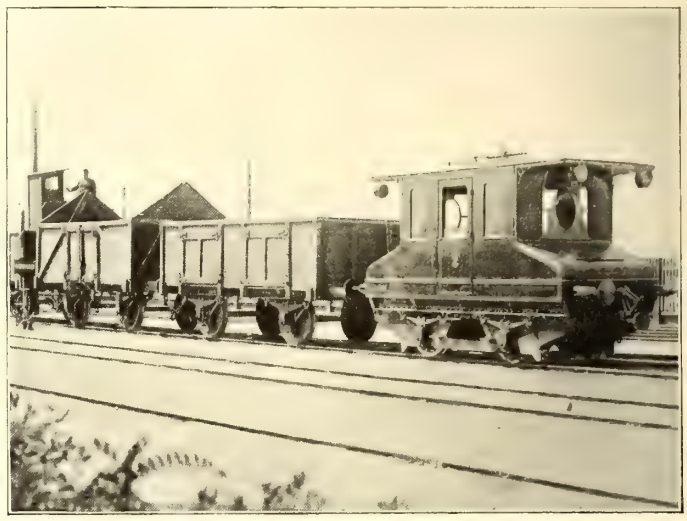
Haarmann rails

STANDARD FORMS OF TRACK CONSTRUCTION

reader is referred to the Street Railway Journal for January, 1899 (International Edition).

The feeders are carried overhead on short roads only. They are usually from 7 mm. to 8 mm. in diameter, of bare copper, and are supported on porcelain insulators, which are attached to poles 5½ meters to 6 meters in height. The underground feeders are imbedded in wooden boxes, and consist of rubber-covered, iron-armored and lead-covered cables. Their cross-section varies from 53 sq. mm. to 140 sq. mm. These cables are furnished by Felten & Guilleaume, Kabelfabrik Actien-Gesellschaft (formerly Otto Bondy), Siemens & Halske, Franz Tobisch, Otto Steiner and Josef Feller, all of Vienna.

OVERHEAD CONSTRUCTION



It is needless to say, the trolley system has been principally employed in Austria as well as Hungary. In the interior of the city ornamental iron poles are used, manufactured by the German-Austrian Mannesmann Tube Works at Komstau, or latticed poles with single or double brackets 2¼ m. in length. Outside of the city limits and in suburban districts wooden poles with wrought iron brackets are used. Several of these poles are shown in the accompanying illustrations. In streets of from 20 meters to 30 meters width, where span wire construction is used, the span wire is of galvanized steel wire 5.6 mm. in diameter, and of a tensile strength of 75 kg. per square cm., with its lowest point about 5.5 m. above the track. In general, the size of the span wire is made to depend upon the width of the span, *i. e.*, the distance between the poles or wall

MOTOR CAR AND TRAIL CAR, PRESSBURG ELECTRIC RAILWAY

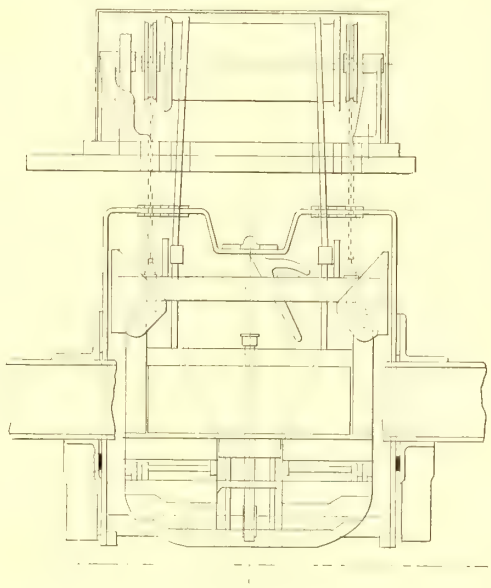
rosettes. These latter are of galvanized soft iron, and are insulated by hard rubber plates. To prevent the transmission of noise, soft rubber bushings are also inserted between the rosettes and the wall. Where heavily loaded span wires have to be attached to light buildings special iron armored rubber cylinders are employed to serve as noise dampeners. The wall rosettes used by the Vienna Ring-Prater line were described in the January issue (International Edition).

The trolley wire consists usually of hard drawn, bare copper wire, from 7 mm. to 8¼ mm. in diameter (53.5 mm.²), and with a tensile strength of 40 kg. per cm.² The conductivity of this wire is about 97 per cent that of pure copper. On the Baden-Vöslau electric road silicon

ELECTRIC LOCOMOTIVE WITH FREIGHT CARS--BUDA-PEST-NEUPEST-RAKOSPALOTA RAILWAY

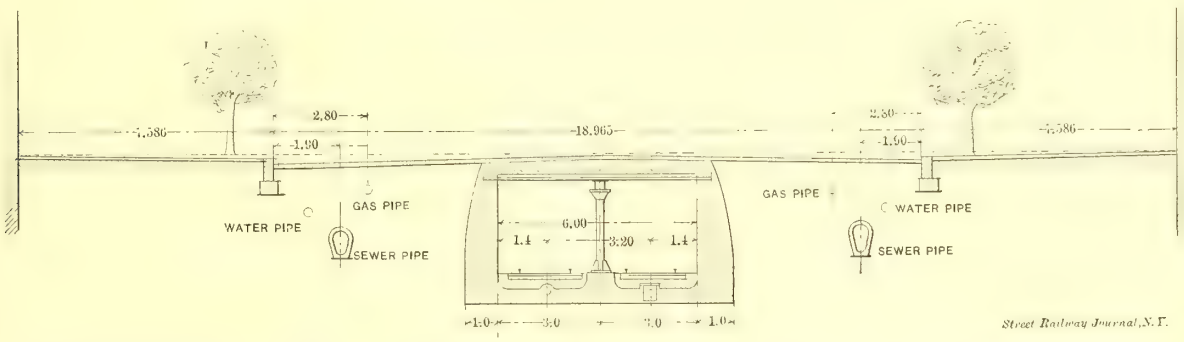
bronze wire, 7 mm. in diameter, is employed. The distance between the poles along the tracks is usually from 30 m. to 40 m. On the Franz-Josef underground electric road in Buda-Pest all the trolley wires in the tunnel are attached to the roof, and those in the open stretches to span wires carried by the poles.

Guard wires are in common use where there is danger of the telephone or telegraph wires coming in contact with the trolley wires, and, in some instances, the bare trolley wire is covered by roof-like narrow wooden laths, which are held in place by means of metal clamps. This device is regarded with great favor by the postal and telegraph authorities, and undoubtedly has considerable utility. The insulators are manufactured by several Bohemian porcelain firms.



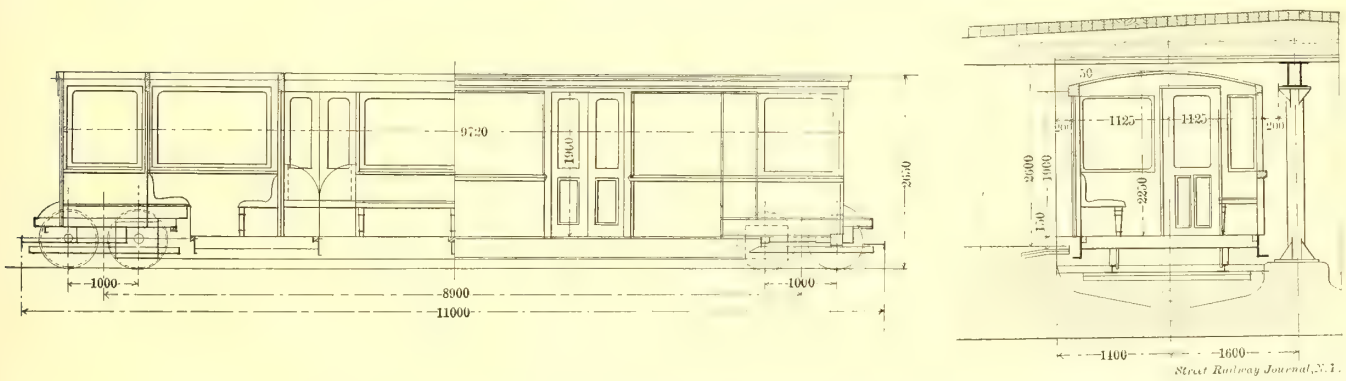
In general, it may be said that the trolley system has overcome the original prejudice which existed against it from æsthetic reasons, and is now popular with the city authorities and general public.

ROLLING STOCK



Of the various types of cars in use, the most popular is the so-called Hamburg type. This car has a long platform at each end, and three windows on each side, two with permanent sash and a central one which may be lowered and raised. Longitudinal seats are used, and the cars have a total seating capacity of twenty with no interior standing room. On the front platform four persons and on the back platform seven persons are permitted to stand, giving the car a total capacity of thirty-one passengers, not counting motorman and conductor. The

length of the car, outside buffers, is 8.4 m.; the greatest width is 2.02 m., and the platforms have each a length of 1.2 m. The car bodies are of wood, covered in places with sheet iron and strengthened in all directions by iron braces. The two side sills are lined with sheet iron, and are reinforced by angle irons; the entire car body is electrically insulated from the truck. The motor cars, illustrated in the January, 1899, number (International Edition), page 46, are typical of standard Austrian practice. On page 42 of the same issue the motor car belonging to the Praterstern-Kagran electric road, and on page 41 that of the Pöstlingberg road, were illustrated. Besides these, the motor cars of the Buda-Pest road were described and illustrated in the July, 1897, issue; those of the Czernowitz Railway, in May, 1899 (International Edition), and those of Graz-Maria Trost, in November, 1898.



In smaller cities, or in cities where there are two classes of fare, as in Lemberg and Czernowitz, cross seats are provided in the cars. Such cars have a seating capacity of from eighteen to twenty and standing room on the platforms and the interior for twelve to twenty persons, exclusive of the motorman and conductor. In other words, thirty to forty persons can be accommodated. These cars are from 5.8 m to 7 m. in length, inclusive of the platforms, and have a width of 2.1 m. The wheel base is from 1600 mm. to 1800 mm. The diameter of the wheels is 750 mm., and the cars have a net weight of from 3.6 tons to 7.7 tons. The weight of the motor car of the Vienna belt line for mixed service, that is, accumulators and trolley, is 12.3 tons. Closed motor cars only are used for both summer and winter service. There are no open motor cars anywhere, but both closed and open trailers are employed. For a time the motor cars were furnished by the Hamburg Street Railway Company, of Hamburg, and the Actien Gesellschaft Elektricitäts Werke, formerly O. L. Kummer & Company, of Dresden, but at present most of the motor cars and trailers are obtained from the Wagen und Waggonbaufabriks Actien-Gesellschaft, formerly Weitzer, of Graz, the Simmering Waggonfabrik, T. Rohrbacher, of St. Veit, Ganz & Company, of Buda-Pest, and the Wagenfabrik, of Arad.

ELECTRIC PLOW, WITH DEVICE FOR RAISING AND LOWERING, BUDA-PEST

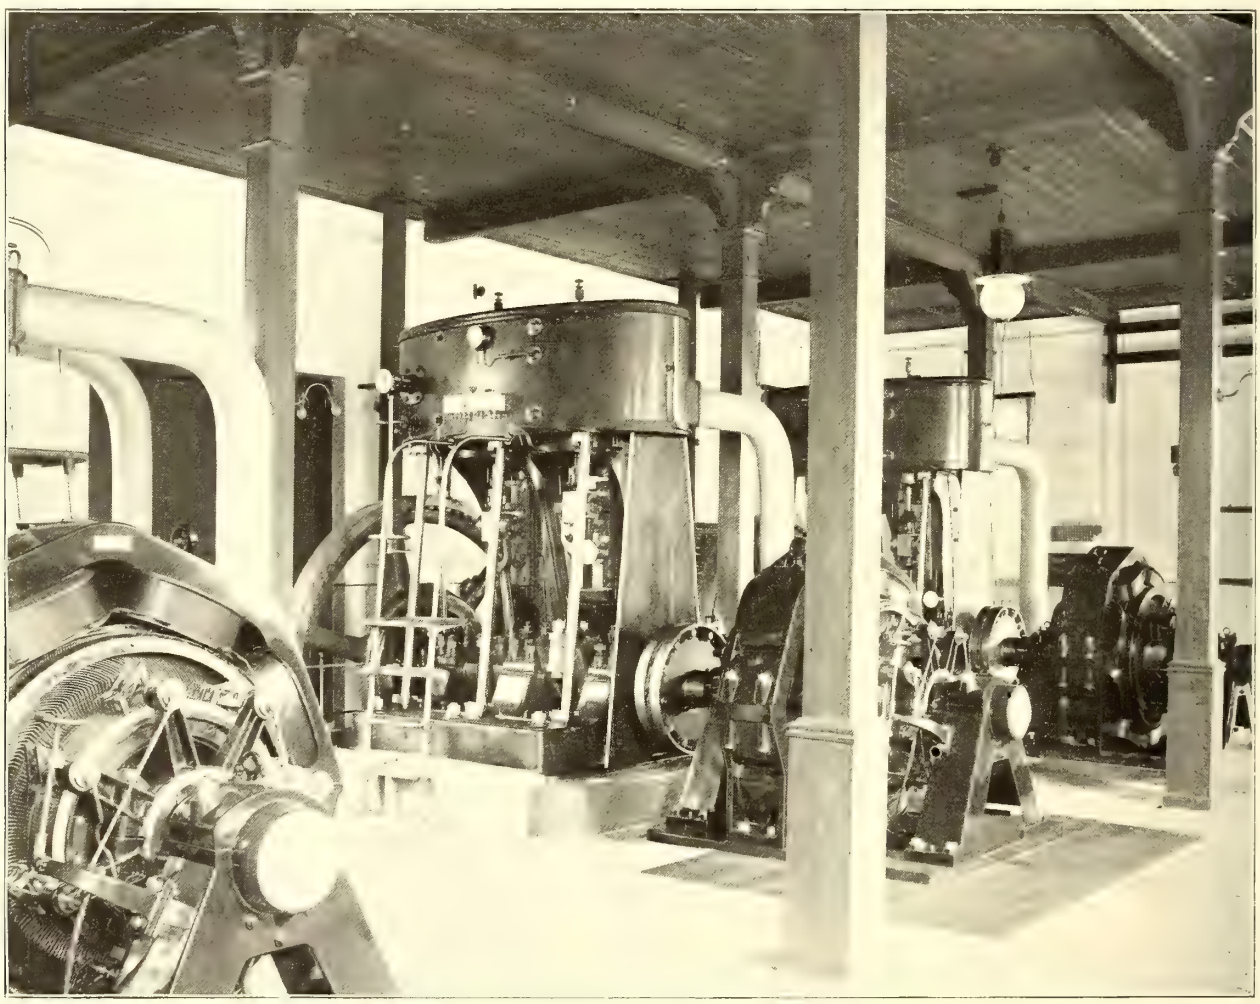
SECTION OF ANDRASSY STREET, SHOWING FRANZ JOSEF UNDERGROUND ELECTRIC RAILWAY—BUDA-PEST

DOUBLE TRUCK CAR, FRANZ JOSEF UNDERGROUND ELECTRIC RAILWAY—BUDA-PEST

The trucks have not been of a uniform type up to the present time, as each of the firms Siemens & Halske, Schuckert, the Berlin Union, Felix Singer, Ganz & Company, of Buda-Pest, and Franz Krizik, of Prag, have had their own particular types. For a time the trucks were obtained only from the Bergische Stahl Industrie, of Remscheid; at present, however, they are manufactured by all the above mentioned firms. Single trucks always carry fenders at each end.

Motors are furnished by the above mentioned firms, as

well as by the Vereinigte Elektricitäts-Gesellschaft, of Vienna, formerly B. Egger. They have a capacity of from 15 h.p. to 25 h.p., with a speed of 550 r.p.m., but those in use on the Buda-Pest underground road have a slightly higher capacity, i. e., 28 h.p. Power is transmitted to the axles by means of chains or ordinary gearing in a ratio of 1 to 3.8. On the Vienna tramway four-pole motors of 20 h.p. and 500 revolutions are used, connected to the axles by means of steel gears.



Each of the above mentioned firms, which furnishes electrical equipment, has its own type of controller, except the firm of Felix Singer & Company, which uses the Walker controller on the Prag-Kozir road. In most cases the controllers are the series parallel type. The best controllers are generally considered to be those of the Union Elektricitäts-Gesellschaft.

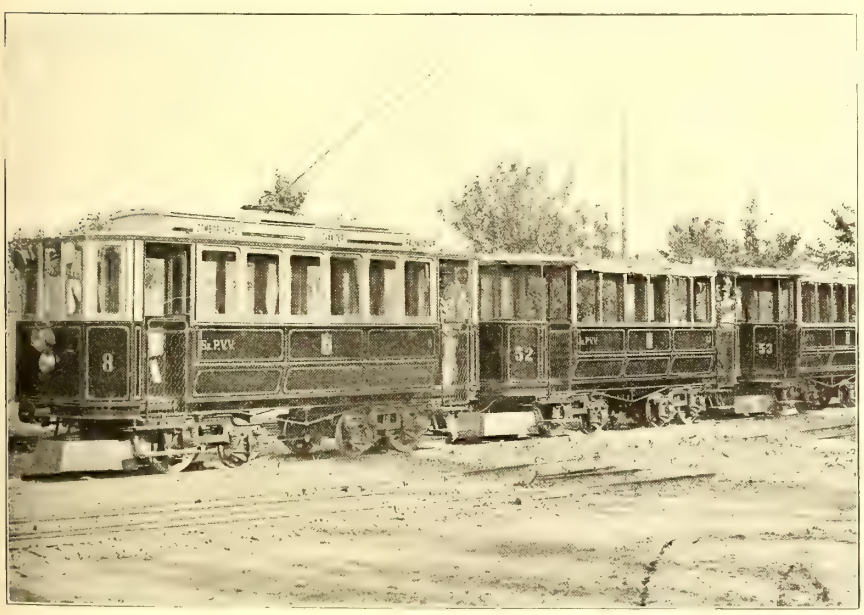
For current collectors in the overhead system the Union Elektricitäts-Gesellschaft, Ganz & Company, and Felix Singer & Company, use the trolley wheel, while Siemens & Halske and Schuckert make use of the sliding trolley, or bow system, which is manufactured in Europe. On the Prag-Kozir road the current is collected at the side, according to the Dickinson system, which was described and illustrated in the Street Railway Journal for September, 1898, page 564. In the bow system the collector consists of a horizontal aluminum U-shaped piece, the groove of which is filled with a semi-solid fat, which continually lubricates the wire. This form of collector has certain manifest advantages over the wheel, and these are apparent particularly in Vienna, where the cars change from the accumulator to the overhead system and vice versa. The setting and reversing of the bow is accomplished in the simplest and most certain manner.

On the Buda-Pest conduit road the current conductors are symmetrically shaped T irons, the broad faces of which are turned toward each other. The contact shoe, which is located beneath the car, can be lowered into or raised from the conduit through the 35-mm. slot within a few seconds. An appropriate mechanism effects the automatic opening and closing of the contact pieces as the shoe is lowered and drawn out of the slot, as shown on the preceding page.

Besides hand brakes, the authorities prescribe the use of electric brakes; the short-circuit brake is generally employed and is operated by means of the controller cylinder. Air brakes are not in use.

The speed, which in all cases is regulated by the authorities, is usually 15 km. per hour; this may be increased to 18 km. in streets with comparatively light traffic, but must be reduced to 10 km. in streets which are narrow and where there is considerable traffic. In the suburbs and in tunnels a speed of from 25 km. to 30 km. per hour is permitted.

ENGINE ROOM OF GUNTRAMSDORF-BADEN-VOSLAU ELECTRIC RAILWAY (VIENNA LOCAL RAILWAY)

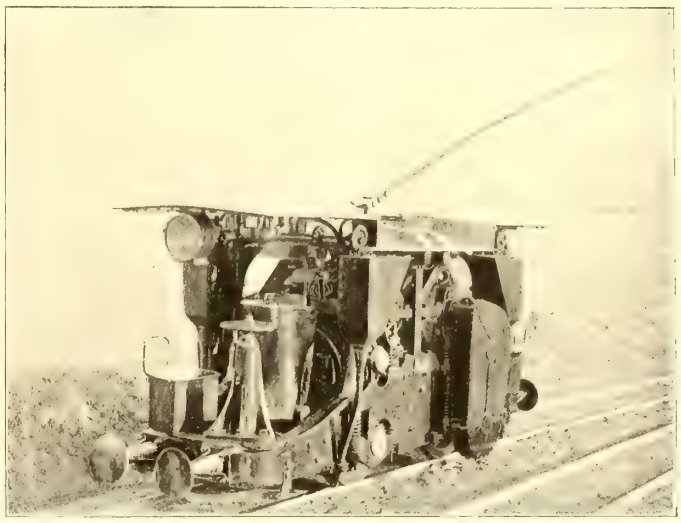


POWER STATIONS

In the design of power stations no uniform rule has been followed, as so much depends on local conditions and the amount of traffic. Upon these points every engineer

and each company has its own views and experiences, on which the design is generally based.

The boilers are usually built parallel to the engines. The latter are usually direct connected to the generators, and only in small installations is belt transmission used. The engines are mostly built by European firms, such as I. Brünner Machinenfabrik, the Prager Machinenfabrik, F. Ringhoffer, of Prag, F. X. Komarek and E. Lenz, of Vienna. In respect to the amount of power used, as well as length of track (172 km., 55 km. of which are conduit), Buda-Pest, with the exception of Hamburg, leads all European cities. The power stations (Gärtnergasse, Palfygasse and Damjanichgasse) generate current for the operation of the city street car lines, city railways and the Franz Josef electric underground roads. The power station in the Gärtnergasse, which furnishes current for the Stadtbahn Actien Gesellschaft, has a capacity of 2800 h.p., and consists at present of three 100-h.p., four 200-h.p. and three 500-h.p. tandem compound engines, which drive thirteen generators. The station in the Palfygasse, which supplies the system of the Buda-Pest Street Railway Company, contains four horizontal tandem compound engines, two of 750-h.p. capacity and two of 350-h.p. capacity. The station in the Damjanichgasse, for the operation of the conduit and overhead lines, is built very similar to the Palfygasse station, and contains four tandem engines of 800 h.p. each. At the smaller stations low-speed engines of from 100 h.p. to 200 h.p. are employed. The size of the fly-wheel depends upon the design of the engine.



In general, water tube boilers of the Babcock-Wilcox type are used. The station in the Gärtnergasse has thirteen water tube boilers, with a total heating surface of 2578 sq. m.; there are six boilers, each with a heating surface of

MOTOR CAR AND TRAIL CARS ON SZABADKA MARIA THERESIOPEL ELECTRIC RAILWAY

262 sq. m., in the Palfygasse station, with a pressure of 10 atmospheres and equipped for the odorless burning of the fuel with step grates and Eggenberg furnace. In the Damjanichgasse station are six water tube boilers of 305 sq. m. heating surface each. The feed water for the boilers is chemically purified before it is used by means of the Dervaux system. In the stations where water is abundant condensers are used, though this is not the usual practice in small stations. The coal consumption per kw.-hour varies, according to the quality of the coal, from 0.8 kg. to 5.0 kg. per kw.-hour.

Boilers are built by the I. Brünner Machinenfabriks Actien Gesellschaft, Dürr & Gehre, of Mödling, L. & C.

ELECTRIC MINING LOCOMOTIVE—NORDUNGARISCHE KOHLENBERGBAU AKT. GES.

Steinmuller, of Gummersbach; Josef Pauker, of Vienna; Breitfeld, Danek & Company, of Blansko; Simmeringer Machinen u. Waggonbaufabriks-Actien Gesellschaft, Th. Schultz & L. Goebel, of Vienna; Prager Machinenfabrik, F. Ringhoffer, of Prag; F. Wannick & Company, of Brünn, etc. According to the size of the stations the heating surface varies between 100 sq. m. and 300 sq. m. The steam pressure is between 8 atmospheres and 10 atmospheres. Labor-saving devices for the transfer of the coal to the boilers have found no employment up to this time. Economizers are sometimes and feed-water heaters are always used.

The generators employed are the standard types of the various electrical companies, and have two or more poles and a comparatively low speed, the two-pole machines being used in small stations only. In Buda-Pest the small steam engines are connected to 400-volt generators, having a speed of 115 r.p.m. and an output of 500 amps. The eight-pole dynamos, driven by the larger engines, have a speed of 110 r.p.m and an output of 1250 amps. at 400-volts pressure. The 800-h.p engines are connected to inwardly-projecting, twelve-pole dynamos of the Siemens & Halske type, having a capacity of 150 amps. at 400 volts, and a speed of 110 r.p.m. The maximum pressure is usually from 500 volts to 550 volts. The electric roads Graz-Maria-Trost and Szombathely are equipped by the Thury system, i. e., high-tension direct with a constant current.

The power stations are generally built as close as possible to the point of utilization of the current, but this depends largely on local conditions. In several cities, for example, in Buda-Pest, where each power station supplies separate lines, the several stations can be connected to-

gether in case of necessity, so that one or the other plant may supply the entire system.

SPECIAL INSTALLATIONS

Special mention should be made of the street railway of Sarajewo, opened on May 1, 1895, and built by the Siemens & Halske Company. It is 4.9 km. in length, has a gage of only 0.76 m., uses the overhead system and serves passenger as well as freight traffic. The latter is carried on by means of electric locomotives and the former by motor cars. The locomotives are equipped with two

ELECTRIC LOCOMOTIVE ON LUMBER ROAD IN MAROS-SZLATINA

20-h.p. motors and the motor cars with one 20-h.p. motor. On both the power is transmitted by means of a chain to one axle on the motor car, and both axles on the locomotive. The Buda-Pest Neupest Rakospalotaer electric, normal gage road, 12.28 km. in length, with overhead trolley, is also of more than ordinary interest. It also serves both classes of service, and for freight haulage electric locomotives are used, which are equipped with two 25-h.p. motors, and have a draw-bar pull of 1200 kg.

Of special interest also are the industrial roads equipped by Ganz & Company, of Ofen, such as the electric mining roads in Bleiberg, Kärnten, Cribay-Mizsérfa, Bagbyasaja, Palfalva-Ettes and Resicza, all in Hungary, as well as the mountain road at Maros-Szlatina. The first of these roads, which is 2.6 km. in length, was built in 1892, and the current is furnished by a turbine-driven generator at 220 volts pressure.

On page 691 is shown the electric mining locomotive of in use at Csibay-Mizserfa and Bagliasalja. The engraving above shows the two-truck locomotive of the 20-km. mountain road at Maros-Szlatina, having a 1.1 m. gage, each truck being equipped with a 16-h.p. motor.

In conclusion it should be stated that on the normal-gage Arader and Osanader local road experiments with accumulators are being carried on, which will be continued by the directors of the Hungarian State railways. Trials were also made by the firm Krizik, of Prague, on the branch line Nusle-Modran with accumulator cars, seating forty persons, and the cost for the total trip of 26.6 km., in spite of a heavy grade, was only 38 kreutzer. Further experiments for trunk-line service will be made on the contemplated local road Tabor-Beckyn, in Hungary, and trials will soon be made on the Vienna Stadtbahn with eight cars to test the efficiency of a system by means of which the current is conducted by a rail laid midway between the tracks. According to the officially approved plans of Siemens & Halske groups of four cars are run at a time, and the four motors in each group are distributed over the four cars, so that each group contains four cars with one motor each, and the first and last cars are equipped with switches and current collectors. By means of a single controller cars in a train can be dispatched and braked synchronously, so that the couplings and buffers are seldom used. The train will be equipped, besides an electrical brake, with a vacuum brake of the Hardy type, for which Siemens & Halske have designed a new electric vacuum attachment.

There can be no doubt that the advantages of electric motive power for the operation of street cars, industrial roads, and at an early date railway trains on local and main roads will be in evidence, and that this will exercise a most beneficent effect on conveniences of public travel.

For a great deal of the above material the writer is indebted to Messrs. Braun, Schwieger and Hohenegg, whose important and interesting papers before various societies have been most valuable to advancement in the railway field.

An instance of the economic possibilities of power station apparatus is shown in the case of the Birmingham (Eng.) Cable Railway. This plant was originally equipped with two single expansion engines of 287 maximum h.p., with no special heat saving appliances. The increase in traffic on the road made it necessary to increase the engine power, and as a result, two compound condensing engines of 400 h.p. were installed, and condensing water was obtained from a well in conjunction with a tank and cooling tower. The result was that the consumption of fuel was reduced from about 325 tons per month, or 8.9 lbs. per car mile, to 6.5 lbs. per car mile, and the introduction of economizers further reduced the consumption to 4.7 lbs. per car mile, or about 3 lbs. per h.p. hour. As the line is not a large one, the total saving was not very considerable, but the case is a good one to bear in mind on other roads. Even with the fluctuating loads on an electric railway, the consumption of coal for compound condensing engines of 400 h.p. or more should not exceed from 3 to 3½ lbs. per kw.-hour, and for smaller engines, say from 2½ to 3 lbs. Where these figures are much exceeded, the station engineer should look carefully to his generating plant, independent of other conditions, and see where the leak exists.

The Indianapolis Street Railway Company has begun the building of new winter cars at its shops. The bodies of the new winter cars will be fitted to the new double trucks now used under the summer cars.

ELECTRIC RAILWAY PRACTICE IN ARGENTINA

By E. MANVILLE

In the following description of the initiation of electric street railways in Argentina, the Republic of Uruguay may also be included, since the principal city in that Republic, Montevideo, is so near to Buenos Ayres, the capital of Argentina, that the practice pertaining to Buenos Ayres is likely, in many respects, to be largely followed in Montevideo. Of the cities and towns of Argentina, the various tramway systems of Buenos Ayres represent such an overwhelming proportion of the entire tramway mileage in Argentina that, so far as the author is aware, no consideration has yet been given to the electrical equipment of the tramway systems in the other towns, the energies of all interested in electric railway practice in that country having been devoted to Buenos Ayres.

PASSEO DE JULIO, THE CITY TERMINUS OF THE BUENOS AYRES AND BELGRANO TRAMWAY CO.

The tramway systems of Buenos Ayres, in comparison with the population, are most extensive. Probably few, if any, of the cities of the world have a greater length of tramways per head of population than is that of Buenos Ayres. Practically every street and road within the city proper has a tramway line installed therein. The principal parts of the city, having been built on the lines of the more ancient Spanish cities, are singularly ill-adapted for tramways. The streets are excessively narrow—so narrow, in fact, that, with the exception of a few of the more modern avenues, there is only room for one line of tramways in one street, the return track of the same section having to be carried down an adjoining street. The city, as a whole, is laid on the American system, *i. e.*, the streets in both directions are parallel to each other, dividing the city up into blocks of about 120 metres square. The tramways are entirely owned by companies. The concessions granted to the three original companies, viz.: the City of Buenos Ayres Tramways Company, the Anglo-Argentine Tramways Company and the Buenos Ayres & Belgrano Tramways Company, were not granted by the municipality of Buenos Ayres at all, but by the provincial government of the Province of Buenos Ayres, and are held to be unending; but the tramway concessions granted to the newer companies by the municipality provided for the transfer of the whole under-

taking to the municipality at the end of a considerable term of years. In no case yet, however, have these concessions lapsed, and since it is extremely likely that all the tramway companies will avail themselves of the facilities afforded by electric traction, the dates of these concessions are likely to be considerably extended when powers for the use of electricity are granted by the municipality.

Of the three original companies, the Buenos Ayres and Belgrano Company, to which the author is electrical engineer, is the only one, so far, which has obtained the right to equip its tramways electrically, and in this case the concession for the use of electricity provided that at the end of a term of about ninety years from the date of the new

IN FRONT OF RAILROAD STATION IN BELGRANO

concession the whole of the tramways of the company should revert to the municipality, free of all cost, thus putting an end to the interminable concession for horse tramways originally possessed by this company. The Anglo-Argentine Company—another of the three original companies with interminable concessions—is at present applying for electrical powers, and no doubt one condition will be the substitution of a similar limit of time to the unending concession belonging to this company. Of the newer tramway companies, some of which have obtained concessions for electric traction, the term for which the electrical powers have been granted, at the end of which time the tramways will revert, free of cost, to the municipality, is generally sixty years, although this term is varied in individual concessions.

The tramway companies of Buenos Ayres have so far been entirely independent commercial concerns, uncontrolled by manufacturing companies or great syndicates, and each company has operated its system without regard to the other companies. For those companies installing electric traction on their systems fresh capital has been provided by tramway shareholders, principally in England, unaided by manufacturing companies or large syndicates. One exception, however, is that of the Anglo-Argentine Tramways Company, the capital for the electrical reconstruction of which system is, it is understood, being provided by a powerful syndicate backed by one of the large electric railway manufacturing companies. The apparatus so far employed in the electrical equipment of these tramways has been invariably imported from abroad, no part of the equipment having been made locally, and the electrical apparatus so provided for this purpose has been principally obtained in the United States. It is, however, probable that in the immediate future further apparatus required for the equipment of these systems may be imported partly from Germany and partly from England.

The companies owning the tramway systems of Buenos Ayres are nine in number, and are as follows:

The Anglo-Argentine Tramways Company.
The City of Buenos Ayres Tramways Company.
The Buenos Ayres & Belgrano Tramways Company.
The Grand National Tramway Company.
Buenos Ayres (new) Tramway Company.
La Capital Tramways Company.
Metropolitan Company.
Rural Tramway Company.
Electric Tramway of Buenos Ayres Company.

Of these, the La Capital Company, the Buenos Ayres & Belgrano Company and the Electric Tramway of Buenos Ayres, have actually equipped their systems electrically, or are engaged in doing so, and the Anglo-Argentine Company and the Metropolitan Company are obtaining, or have obtained, concessions for the same purpose. The other companies are likely to follow suit, and concessions have been granted for several new tramways, which propose to construct electric tramways from the outset.

All the tramway companies, whether working by horse or electricity, are very much under the control of the municipality. This body imposes a tax of 6 per cent of the gross receipts for the maintenance of the paving of the roads in which the tramways are situated, and further, enforces a payment of from a quarter to a half of the cost of newly paving any street in which existing tramways run. In granting concessions to these companies for electric traction a further tax has been imposed upon the com-

ON ROAD TO BELGRANO

panies in the shape of the gratuitous service of a certain number of electric arc lamps, one per block in the case of some concessions and two in the case of others. Furthermore, the municipality reserves to itself the right, which is frequently exercised, of giving powers to any tramway company to run for a distance not exceeding three consecutive blocks over the tramways of another company, on the payment to the owning tramway company of a

variable sum per block per annum. The municipality further reserves to itself the right to stipulate the headway of the cars on the various systems and to regulate the fares charged, though, on the other hand, it does not in any way supervise the accounts. As a result of the right of the municipality to regulate the fares the prosperous companies are not anxious to show large dividends upon their capitals. Owing, however, to the considerable overcapitalization of most of the horse tramways, few companies show good financial results. Furthermore, the proportion of working expenses to gross receipts usually exceeds 70 per cent, notwithstanding the low price of horses and fodder, and it is hoped that the introduction of electrical traction will materially improve the dividend earning capacity of the various systems. The development of electric railroading will undoubtedly be largely in city and suburban traffic, there being no settlements of any importance within easy distance of the capital to encourage the development of interurban electric railways.

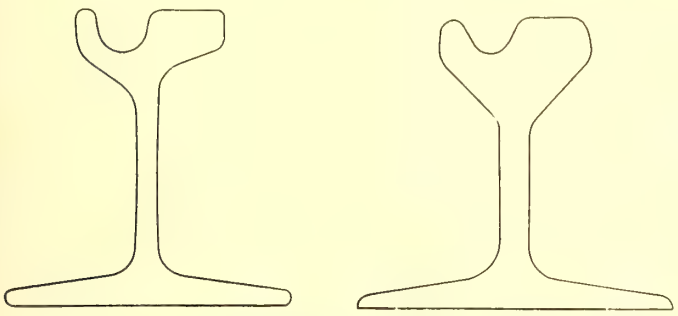


FIG. 1.—OLD HORSE RAILWAY SECTIONS IN BUENOS AYRES

The municipality has persistently refused, in granting concessions for electric traction, to allow the use of overhead wires within a considerable portion of the center of the city, and has stipulated that, while overhead wires may be used without this portion of the city, either the conduit or the surface contact system, or accumulators must be used within. The tramway companies at present operating within this prescribed district have thus been prevented from carrying their concessions into effect so far as this area is concerned. The streets of Buenos Ayres Ayres are peculiarly ill-adapted for an open conduit system, owing to their extreme narrowness and the fact that within these narrow streets are contained the pipes of four gas companies, four electric light companies, the city's water system, and the sewers, and it is questionable whether room could be found for the reception of these various pipes if a portion of the road were occupied by the tramway conduits. Furthermore, the expense of altering the positions of so many pipes and the sewers, which is quite an unknown quantity, could not be estimated. It has been felt by the tramway companies that the surface contact system has not yet had sufficient trial to warrant its use to meet the conditions of the concession, and accumulators are also regarded by these companies as too expensive to be seriously entertained. It is hoped, however, that the municipality will shortly remove this restriction—at least so far as the bulk of the inside of the city is concerned, with the exception of the central square, around which most of the tramways pass, where either an open conduit or surface contact systems might be installed without regard to the cost. Until this alteration in the decision of the municipality is arrived at it is unlikely that the electric tramway systems will be extended through the principal internal streets of the city.

ROAD-BED PRACTICE

The early method of constructing horse tramway tracks in Buenos Ayres has been primitive in the extreme. Girder rails of heavy weight, but of very bad running section and external section, have been universally adopted, the sections used by almost all the companies being of the two types shown in Fig. 1, weighing 103 lbs. and 75 lbs. respectively per yard. These rails were laid direct upon the road without any foundation, either of cross ties or concrete, with the result, after a very short time of running, that may be easily imagined. In the reconstruction of the tramways for electrical purposes Fig. 2 shows the

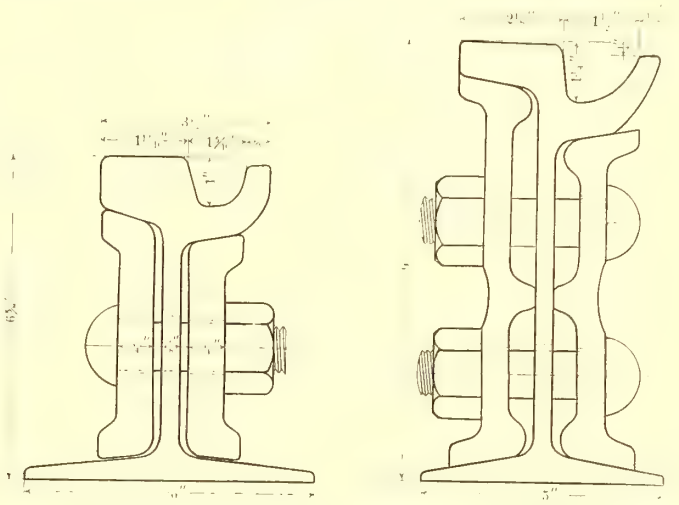

FIG. 2.—NEW ELECTRIC RAILWAY SECTIONS IN BUENOS AYRES

section of rails now being adopted of from 85 lbs. to 87 lbs, per yard run in weight. These rails are being laid in three ways. Fig. 3 shows them laid upon a concrete base extending the whole width of the track; Fig. 5 shows them laid on longitudinal concrete sleepers, one under each rail, and Fig. 4 shows the rail laid on cross ties of hard native wood called *quebracho*, the cross ties themselves being supported on a foundation of broken brick or stone. These three forms of road-bed are used respectively in different parts of the city according to the wheel traffic which predominates therein. The rails, supported on a complete concrete base, are used in the business center; those on the longitudinal concrete sleepers toward the outskirts, and those on cross ties in the suburbs, where the traffic is lightest. The space between the rails is paved with either wood, asphalt, stone sets, or macadam, as shown in the illustrations. Here, again, the wood paving and asphalt predominates in the center of the city, where the rails are laid on a complete concrete base, the stone setts, where the rails are laid on longitudinal concrete sleepers, and macadam, where the rails are laid on cross ties. The wagon traffic in Buenos Ayres, being, however, chiefly carried on by means of very heavy two-wheeled vehicles drawn by bullocks, there is a great tendency to wear down the macadam when used next to the rails, and it is the author's opinion that that form of paving will give place entirely to the use of stone setts, which form a more adequate protection to the track itself. It will be noticed from Fig. 2 that the modern section of rails used for the electrical reconstruction of these tramways has heretofore been of two types—one 9 ins. in depth, the other about 6⅝ ins. in depth. The 9-in. rail is

obviously too light structurally and has too narrow a base to give satisfactory results in maintenance, and so far as the electrical tramways of the Buenos Ayres & Belgrano Company are concerned, the 65-in. rail is now exclusively adopted. It will be noticed from Figs. 3, 4 and 5 that, owing to the small height of these rails, special attention has to be given to supporting the very deep stone setts, which are used in Buenos Ayres, and where the rails are mounted on a longitudinal concrete sleeper a mixture of cement and sand in equal parts is laid around the lower part of the rail to raise it up to the surface of the granite

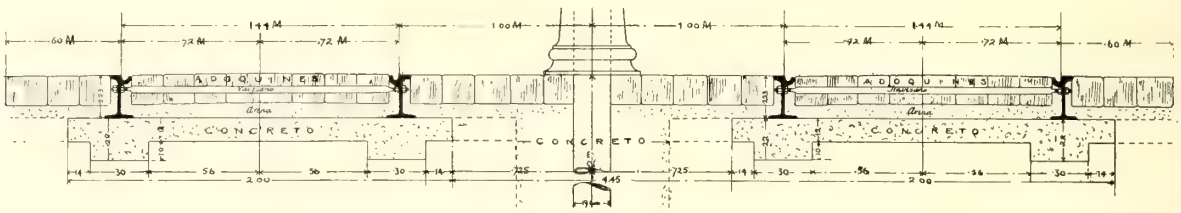

FIG. 3.—ROADBED CONSTRUCTION WITH CONCRETE BASE

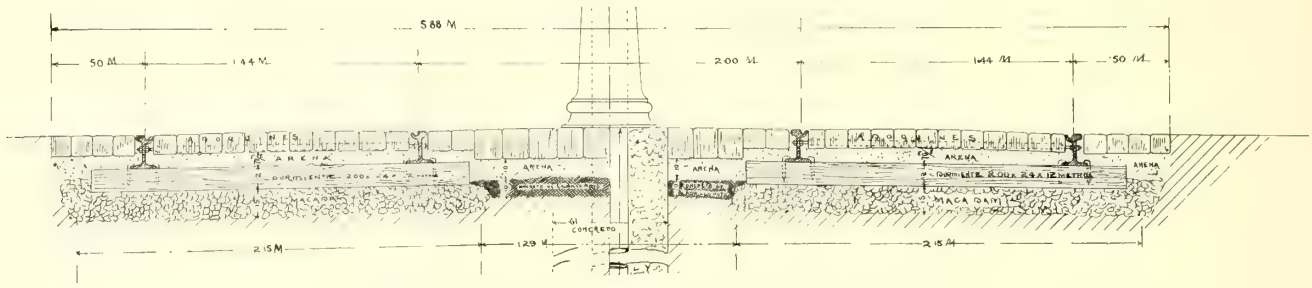

FIG. 4.—ROADBED CONSTRUCTION WITH WOOD TIES

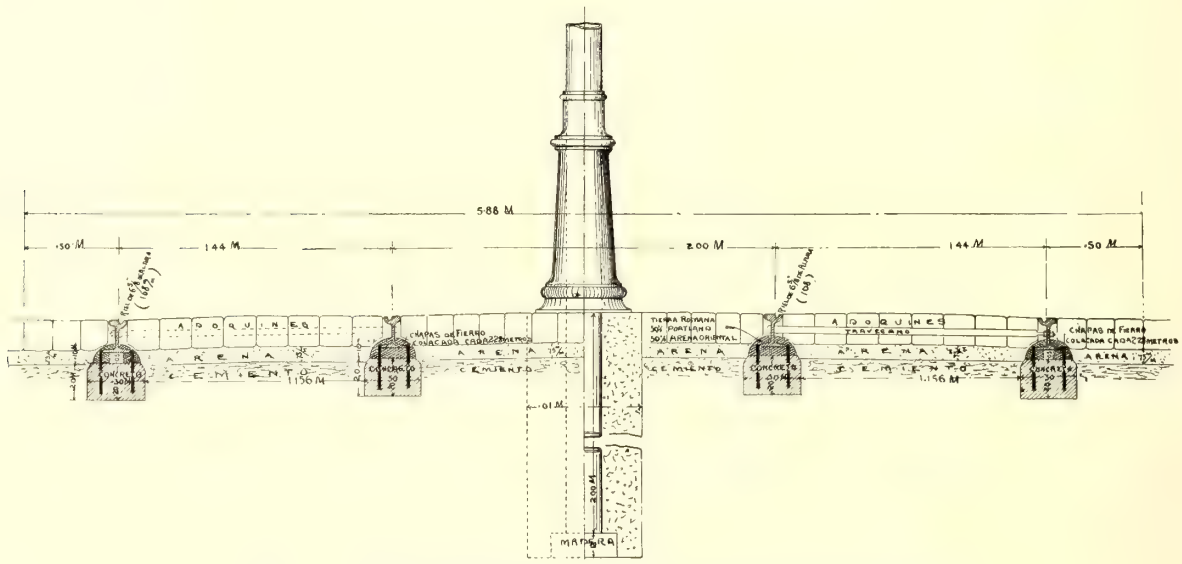

FIG. 5.—ROADBED CONSTRUCTION WITH CONCRETE STRINGERS

setts and to effectively support the latter, which are shaped to sit around the upper part of this concrete block.

Special attention has been given to the composition of the rails in order to insure their wearing quality under the onerous conditions existing with the use of electric motor cars. The rails are made of the best description of Bessemer steel, containing not less than 0.45 per cent of carbon. They are very cleanly and evenly rolled, each rail being made from a single ingot or part thereof, and free from all cracks, blisters, flaws or rough edges. They are seen to be perfectly straight when delivered, made to template throughout the entire length and straightened by pressure and not by hammering. These rails have been principally supplied by the Johnson Company, of Lorain, Ohio, and the Pennsylvania Steel Company.

These new types of rail, having an excellent external section, the joints between them are made by suitably designed fish-plates, and no trouble has been experienced yet in keeping the joints so made in perfectly good order. As, however, some of the companies reconstructing their roads for electric traction had recently laid rails of the two older sections shown in the figure, which were comparatively new, and therefore not to be discarded if possible, it has been arranged, in the case of the Buenos Ayres & Belgrano Company, that the joints of these rails should be cast welded on the "Falk" system, so as to render them suitable for mechanical traction, and this company has at present in use a complete "Falk" welding plant, including sand-blast and grinding outfit to insure the joints so made being perfect of their kind. It is obvious from an inspection of the section of these two types of rails that no satisfactory fish-joint could be made that would withstand the weight of the heavy motor cars constantly passing thereover.

The switches, mates and curved crossings have chiefly been made by the manufacturers of the rails, and are principally of cast steel. In the case of special crossings,

however, these have been built up locally of the standard section of rail, but in place of the joints being fished, they have been keyed together by iron being cast around them, suitable holes being formed through the web of the rails, through which the molten iron runs to key the whole mass together.

The municipality requires that the various sections of rails and the method of road construction be submitted to them for their approval before the work can be put in hand. The electrical bonding of the rails is, in the case of the Buenos Ayres & Belgrano Tramways Company, effected by the use of one Edison-Brown plastic bond and one 0000 Chicago bond to each rail length where the joints are fished, and one Chicago bond only where the rail joints are cast welded, the two lines and two tracks being suitably cross bonded. All of these bonds have, of course, been imported from the United States.

DISTRIBUTION SYSTEM

Of the electrical tramway systems actually at work at present, viz., those of the La Capital Company and the Buenos Ayres & Belgrano Tramways Company, two methods of distribution have been used. In the case of the La Capital Company the feeders are partly laid under ground in a wooden conduit and partly carried overhead on the standards supporting the trolley wire. On the Buenos Ayres & Belgrano system the feeders have been laid under ground entirely. The cables are divided into two groups, one being the "distributors," each running parallel to the tramways, and feeding at intervals into the trolley wires, and the other "feeders," which feed into the distributors at suitable points. Both types of cable are paper insulated and lead sheathed, without any further protection over the lead sheathing. These feeders and distributors are drawn into multi-way stoneware ducts laid beneath the foot-paths. The inside surfaces of these ducts, in contact with the lead-sheathed cables, are highly glazed, so that any further protection to the lead-covered cable would be useless, if not an actual disadvantage. The whole of the feeder system is laid out with a view to sustaining the least possible loss of electrical energy therein, having regard to the necessarily high price of electrical energy. Fig. 7 is a diagram showing the electrical energy to be conveyed to the various points on one of the Belgrano Company's two tramways and the maximum drop of electric motive force allowed at any point along the system. To obtain these results it will be observed that negative feeders are used, with negative boosters, and that the positive feeders to the extreme ends of the system have positive boosters working in connection therewith.

The lead sheathing of the cables is bonded at intervals to the rails to prevent any difference of potential between the rails and the cable sheathings, which would result in electrolytic damage to the lead sheathing of the cables. The municipality has not, so far, issued any regulations as to the conditions under which the distribution shall be effected, but in this particular case the principle has been adopted of working well within the Board of Trade rules governing in Great Britain.

The connections between the feeders and distributors, and between the distributors and the trolley wires, is effected through multi-way switches and fusible cut-outs arranged in section pillars placed on the footways, which are so commonly coming into use in Great Britain. The same section pillar contains a telephone enabling the guard, or any tramway official, to communicate with the central depot, and also contains suitable lightning arrester apparatus to guard the trolley wire and feeders. The tramway tracks are divided into sections a kilometer long, and at each section is placed one of these section pillars, the up-and-down trolley wires being provided at these points with section insulators, and the cross-over roads between the up and down tracks are also, for convenience sake, placed at these sectional points, a special switch being arranged in the section pillar to switch out the trolley wire over the cross-over when not in use. Fig. 8 is an illustration of one of these sectional switch pillars.

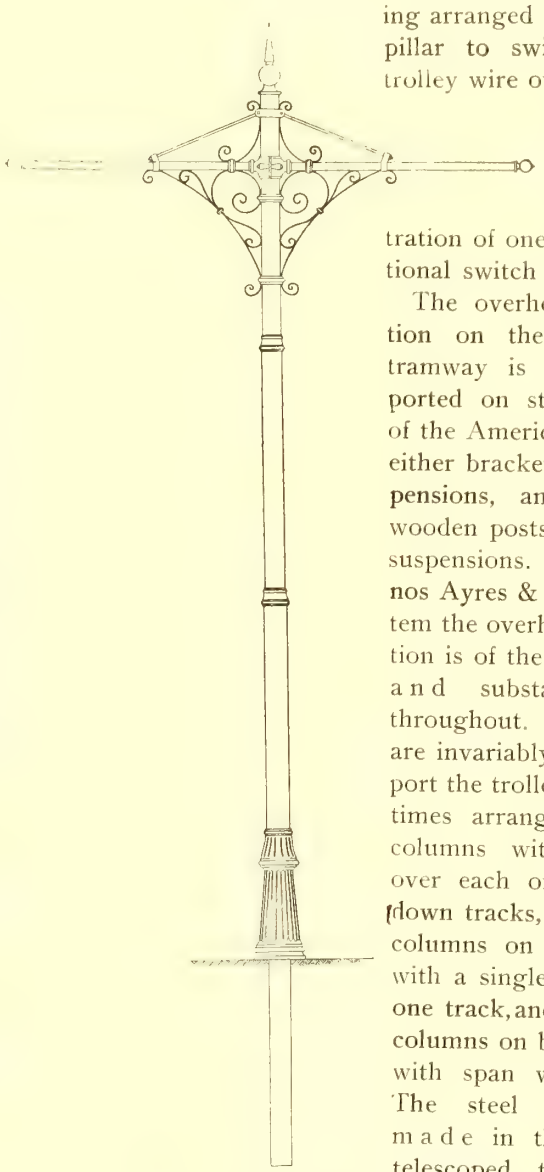

FIG. 6.—IRON POLE IN BUENOS AYRES

The overhead construction on the La Capital tramway is partly supported on steel standards of the American type, with either bracket or span suspensions, and partly on wooden posts with bracket suspensions. On the Buenos Ayres & Belgrano system the overhead construction is of the most modern and substantial type throughout. Steel columns are invariably used to support the trolley wire, sometimes arranged as center columns with a bracket over each of the up and down tracks, sometimes as columns on the sidewalk, with a single bracket over one track, and sometimes as columns on both footwalks with span wire supports. The steel columns are made in three sections, telescoped together, and for the main run of the tracks are of the following dimensions:

Top, 5 ins. diameter x .26 in. thick.
Middle, 6 ins. diameter x .30 in. thick.
Bottom, 7 ins. diameter x .40 in. thick.

While at each kilometer section columns of a larger size are used and of the following dimensions:

Top, 6 ins. diameter x .30 in. thick.
Middle, 7 ins. diameter x .40 in. thick.
Bottom, 8 ins. diameter x .60 in. thick.

And at those points where it is desirable to securely anchor the line, columns of the following dimensions are used:

Top, 7 ins. diameter x .40 in. thick.
Middle, 8 ins. diameter x .60 in. thick.
Bottom, 9 ins. diameter x .80 in. thick.

In addition, columns of the same dimensions as those above described for use at the sections are used along the length of the line at certain points where the municipality stipulates that arc lamps are to be erected, the columns in this case having to carry the connections from the underground feeders to the arc lamps.

The overhead fittings of the Belgrano road are all of the most modern and substantial type, the insulators being of the "West End" pattern, and, generally, no expense has been spared in making the overhead system neat in appearance and substantial in construction. The size of the trolley wire used is 00, and is of hard drawn copper.

getting onto and leaving the cars. The Buenos Ayres & Belgrano Company has therefore also provided a large number of single-deck combination cars, arranged to be opened in fine weather and closed in bad weather, and which, dispensing with the service of a second guard, seem, on the whole, to meet the conditions better than the double-deck cars. The municipality requires under its regulations that in the winter time the cars shall be closed and in the summer time opened. The double-deck car, which in itself is both partly open and partly closed, met this condition very well, since at all times of the year the passenger could choose the closed or open part of the car

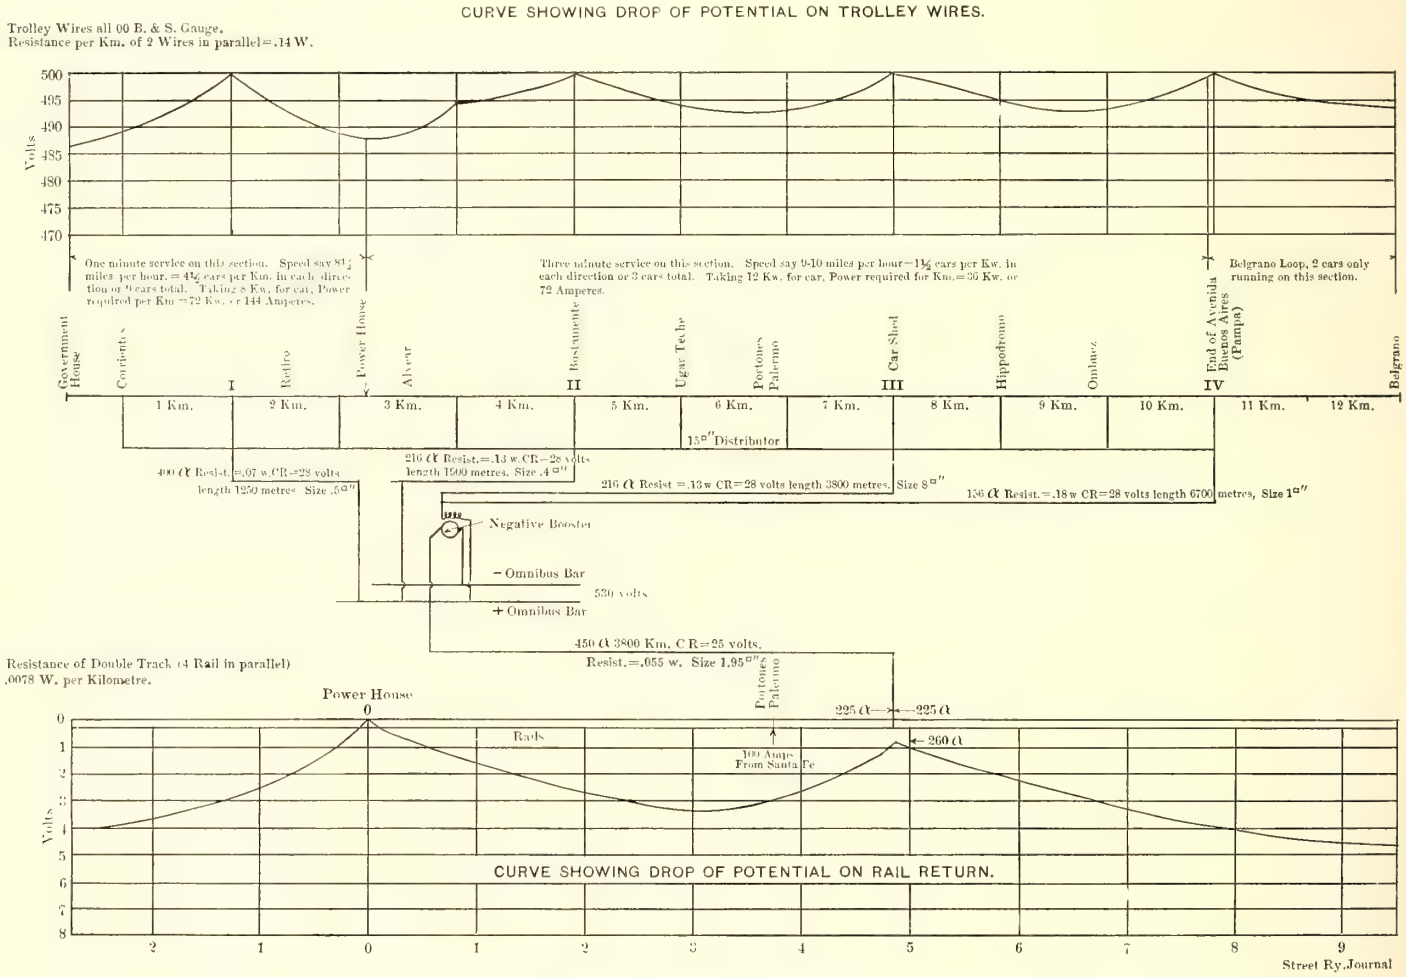

FIG. 7.—DIAGRAM OF DISTRIBUTION CIRCUITS, BUENOS AYRES AND BELGRANO TRAMWAYS

ROLLING STOCK EQUIPMENT

The rolling stock equipment on the two electric tramway systems at present running, viz.: the La Capital Company and the Buenos Ayres & Belgrano Company, embraces several types of cars. It was originally maintained that the country, with a Spanish population, would not use the upper deck of double-deck cars. La Capital Company, however, provided itself solely with an equipment of this description and met with complete success in the use of both decks, in all the better kind of weather the upper deck being extensively patronized; and the Buenos Ayres & Belgrano Company is now introducing on its system of cars of this description. These double-deck cars have an "imperial" over the upper deck so as to shield the passengers thereon from the rays of the sun and also to carry the trolley arm. In the practical use of these cars, however, difficulties have been experienced, owing to the large number of passengers crowding on to a single car, in collecting fares and in the speedy disposal of the passengers as desired. The combination car, however, meets this regulation even better than the double-deck car, as it is completely converted into either an open or a closed car as the season of the year may require. Until lately combination cars with removable panels of the type made by the Barney & Smith and Jackson & Sharp companies have been used, but they have the disadvantage of requiring some little time to be spent in the conversion of the car from open to closed or vice versa, and the Buenos Ayres & Belgrano Company is now introducing on its system some of the new type of Brill cars, in which both the panels and windows slide up into the roof, enabling the change from open to closed, or vice versa, to be effected in a few minutes. It is believed that this type of car will prove eminently satisfactory in meeting the conditions.

The cars are mounted on both Peckham and Brill extra long trucks, where the length of the car over the platform does not exceed 28 ft., and on Peckham and Brill double trucks, where the length of the car exceeds that dimension.

The tramway tracks, being as a rule very straight and the curves where necessary being of comparatively large radius, wheel-bases of from 7 ft. to 7 ft. 6 ins. are in use with the single trucks. All the trucks at present in use have been imported from the United States from the makers mentioned, and none have so far been made locally. In Fig. 9 is shown a removable panel, combination Barney & Smith car used on the Belgrano system, and in Fig. 10, a double-deck car, with an imperial, while in Fig. 11 is shown the Brill convertible car.

The rolling stock on both the La Capital and the Belgrano systems are equipped with motors of the General Electric Company's make. Those of the La Capital Company are of the G. E.-800 size, and are not fitted with electro-magnetic brake attachments. The cars in use on this system are smaller, on the whole, than those used on the Belgrano system, and this size of motor equipment is ample for the requirements of the line. On the Belgrano system the G. E.-1000 motor equipment is being invariably used, and the General Electric Company's electro-magnetic brake attachment is also provided. Having regard to the fact that in some parts of the city the cars have to slow up at the end of each block of 120 meters, the electro-magnetic brake has proved particularly useful, enabling a high average speed to be maintained, notwithstanding the constant slowing. Controllers used on both systems are of the General Electric Company's make, those on the Buenos Ayres & Belgrano Tramways having the requisite extra number of brake contacts, and these controllers have all been imported from the United States. The trolleys employed are on the most modern United States system, and are also imported.

The municipality regulates the number of passengers that may be carried on the cars, and these are restricted to the proper number accommodated by the seats in the cars, except that three passengers are allowed to stand on each platform. This limit to the number of passengers has been fixed by the municipality, not so much with regard to the comfort of the passengers themselves as to the number of passengers on a single car that the horses ordinarily in use on the horse tramways are judged capable of hauling, and now that electric traction is being introduced on some of the tramways, it is likely that the restriction as to the number of passengers on the platforms may be removed. The platforms on most of the cars are 4 ft. long, and therefore would accommodate a considerable number of passengers. There have been so far no restrictions made as to the speed at which the cars shall travel, this being limited only by the exigencies of the other traffic over the tramway lines. Thus, at the outskirts of the city the cars travel at as high a speed as from 12 to 16 miles an hour, while in the business center a greater running speed than 8 miles an hour is not practicable. So far, great difficulty has been experienced in obtaining drivers sufficiently careful in the running of the cars to prevent accidents to persons crossing the tracks, and in the case of the two companies at present running electrically, quite a considerable number of fatal accidents have occurred. All the cars, however, are now being equipped with the "Providence" fender, and it is believed that the use of this will materially diminish the number of accidents of this kind.

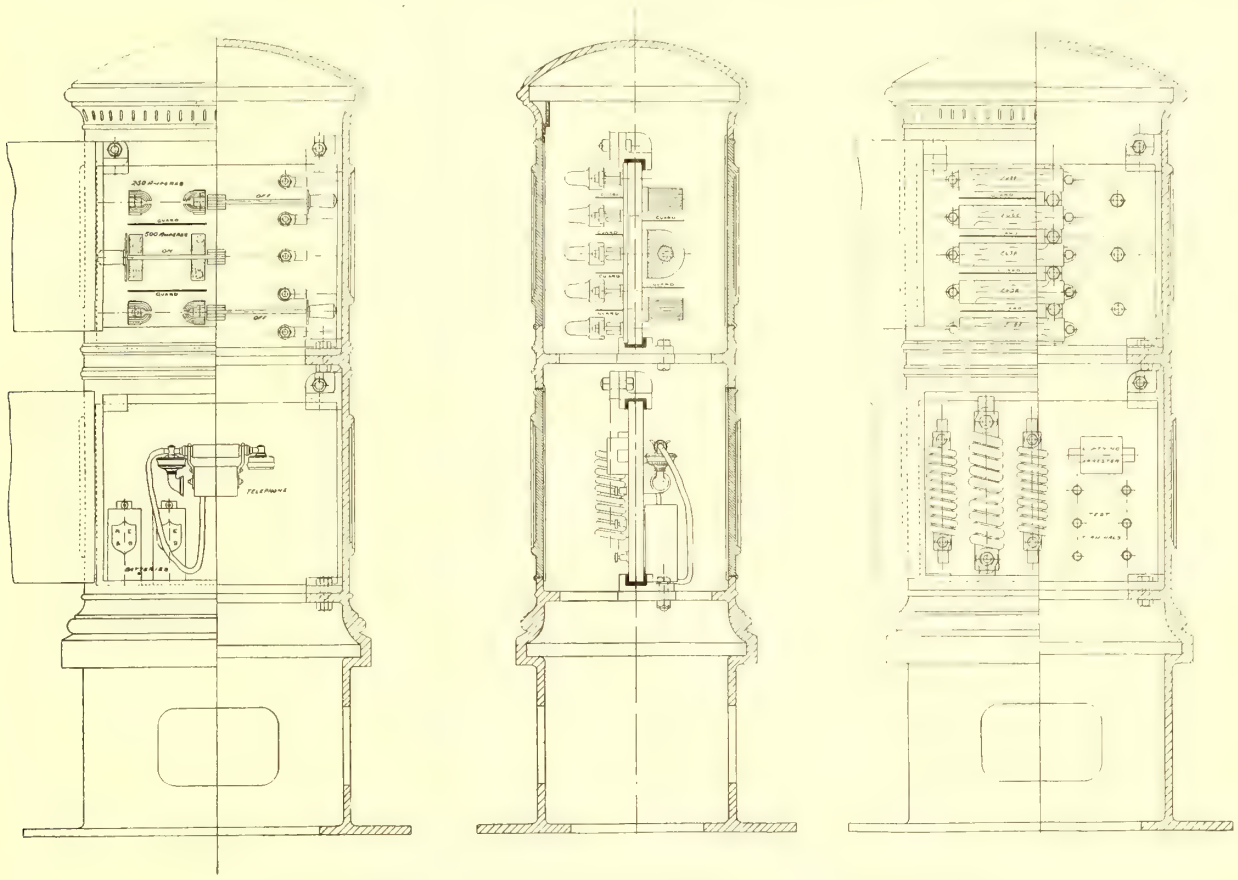

FIG. 8.—FEEDER AND SECTION SWITCH PILLAR, BUENOS AYRES

POWER STATIONS

Of the two tramway companies at present using electricity for their tramways, the La Capital Company has a power station of its own, while the Belgrano Company has made arrangements with one of the four electric lighting companies in Buenos Ayres to supply it with current.

There, therefore, cannot be said to be any general plan on which the tramway power stations of Argentine are built. La Capital Company is using Stirling boilers with Green's economizer, direct-coupled Ball & Wood engines and Walker generators. The boilers and engines are placed at right angles to each other, probably on account

FIG. 9.—COMBINATION CAR, BUENOS AYRES AND BELGRANO TRAMWAYS CO.

of the exigencies of the site, and a single range of steam piping is used. The plant installed by the lighting company, from whom the Belgrano Company purchases its current, consists of 500-kw. engines and generator, made respectively by the McIntosh-Seymour Company and the General Electric Company. This company has, in addition to the special plant installed for the current directly supplied to the Belgrano Tramway Company, a considerable plant for the production of electrical energy for lighting purposes, consisting of direct-coupled, compound "Allis" engines and monocyclic alternators of the General Electric Company's make. No special spare steam plant has been provided by the lighting company for the supply of current to the Belgrano Company, and for this purpose motor generators receiving their energy primarily from the monocyclic alternators have been installed. A 1000-kw. direct-current plant has been, up to the present time, provided for the supply of energy to this tramway company, together with one 500-kw. motor generator as a spare. The boilers used by the lighting company are of the Belleville type, and the steam range is arranged on the ring system. In all there are installed in this lighting station about 3000 kw. of generating plant. The same company will probably supply electrical energy for the running of a part of the Anglo-Argentine Company's system when this is electrically equipped, and the Anglo-Argentine Company will probably have, in addition, a multiphase generating station of its own to enable it to economically distribute current through static and rotary converters to the remaining portions of its very extensive system.

Automatic stokers are not usually employed on the boilers in the Buenos Ayres generating stations, owing to the fact that Welsh steam coal is almost invariably used, and this coal is not of a description that can be best dealt with by automatic stokers.

The fact that the supply of current to the Belgrano system is obtained from one of the lighting companies has prevented the most suitable position for the power house being selected, and as a matter of fact it is situated very near one end of the line, necessitating the use of both positive and negative boosters, which would probably not have been required had the generating station been situated somewhere near the center of the system. The first illustration gives a very good idea of the arrangement of the tramways and overhead construction along the Passeo de Julio, one of the important boulevards along which the Buenos Ayres & Belgrano system extends, and shows clearly how little obstructive, from an æsthetic point of view, is the arrangement of the overhead construction. In this boulevard the system adopted almost exactly resembles that employed at Hamburg, Germany, where a somewhat similar arrangement of boulevards with grass plots and trees exists.

FIG. 11.—IN THE SUBURBS OF BUENOS AYRES

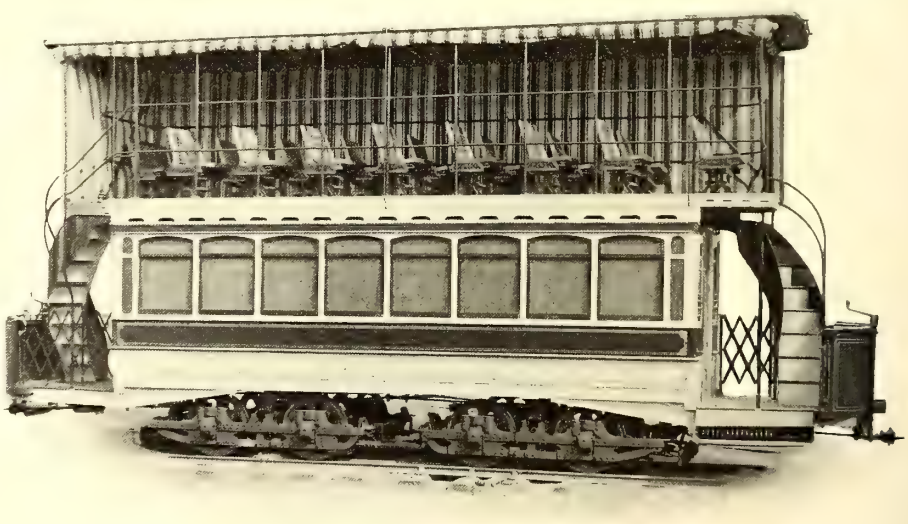

FIG. 10.—BUENOS AYRES CAR WITH TOP SEATS AND IMPERIAL

THE SERVICE PERFORMANCE OF RAILWAY MOTORS

BY W. B. POTTER

The conditions imposed in railway service are so intermittent and varied that it is not possible to establish a standard factory test that will meet all the requirements of actual practice. The General Electric Company has therefore adopted, as representing extreme conditions, an arbitrary standard, based on temperature rise of the motor of 75 degs. C. in one hour, the temperature of the surrounding air being assumed at 25 degs. C. The horse power rating obtained on this basis represents only one hour's continuous run and the temperature of the motor will rise to an injurious point if it is operated for an extended time at the rated output.

While a railway motor cannot be operated continuously at the rated horse power without injurious heating, this output can be exceeded for short periods of time, as in rapidly accelerating a car or climbing short heavy grades, but for ordinary service the average horse power required of a motor throughout the day should not be greater than 30 per cent of its horse power, rated on the hourly basis, which will give a temperature rise of about 60 degs. C.

These figures are based on a line potential of 500 volts, and the average rating of the motor may be increased approximately as the voltage is increased. For example, if a motor wound for 500 volts be operated on a potential of 550 volts, the average output may be increased about 10 per cent.

When electric brakes are proposed, a motor of greater capacity must be used, since the heating of the motor is increased from 20 per cent to 25 per cent by the use of electric brakes, this extra heating depending on different conditions of service. The minimum increase of 20 per cent represents a service containing few grades and stops, and the maximum of 25 per cent should be allowed on hilly roads with frequent stops, where the electric brake will be in use a large part of the time.

HORSE POWER OF MOTORS

The total horse power (rated on the hour basis) of an equipment for ordinary city and interurban service may be determined approximately by the following general formulæ. The ton in all cases is taken as 2000 lbs.

$$\text{Horse power} = \frac{(\text{Total wt. in tons}) \times (\text{Maximum speed in m.p.h. on level})}{5}$$

If electric brakes are to be used the formula should be as follows:

$$\text{Horse power} = \frac{(\text{Total wt. in tons}) \times (\text{Maximum speed in m.p.h. on level})}{4}$$

If the maximum speed is not known it can be taken as being twice the schedule speed, since this ratio is usually found in practice.

As an example, assume a 20-ton car with a maximum speed of 50 miles per hour, the line potential being 500 volts, then

$$\frac{20 \times 50}{5} = 200 \text{ h.p., or four 50-h.p. motors.}$$

If the line potential be increased to 600 volts, electric brakes could be used with these same motors, the gear ratio being changed to give the same speed as before.

As another example, consider an ordinary street car weighing, equipped and loaded, 11 tons, the maximum speed being about 25 miles, then

$$\frac{11 \times 25}{5} = 55 \text{ h.p., or two 30-h.p. motors.}$$

If electric brakes were to be used, then

$$\frac{11 \times 25}{4} = 69 \text{ h.p., or two 35-h.p. motors.}$$

The motor capacity required for any given service is so largely affected by the condition of track, grades, etc., that these rules should be cautiously applied, as they are simply a guide to the selection of a motor equipment and indicate the *minimum capacity* under ordinary conditions.

The schedule speed, or speed of the entire run, including stops, is ordinarily about one-half of the maximum speed on a level track, but where stops are frequent this ratio becomes less. In suburban service this figure may be exceeded since the relation between the two speeds is governed by the number of stops per mile the cars are required to make, and the fewer the number the more nearly the schedule speed will approach the maximum speed. For example, if a certain equipment can make a maximum speed on a level of about 25 miles per hour, then the limit of the schedule speed with seven stops per mile will be about 10 miles to 12 miles per hour, while the same equipment, with but two stops per mile, could make a schedule speed of between 15 miles and 18 miles per hour. High schedule speeds with frequent stops require equipments with large motor capacity and problems of this kind should always be treated as special.

TRACTIVE EFFORT

The tractive effort required to move a car or train is dependent on the rate of acceleration, grade and car friction, air resistance being included in the latter. In railway practice acceleration is conveniently expressed in miles an hour per second, that is, an accelerating rate of 1 mile an hour per second means that the rate of speed is increasing 1 mile each second and that in twenty seconds, for example, at this rate, the speed will be 20 miles an hour. One mile per hour per second is equivalent to 1.466 ft. per second.

Excluding car friction, a tractive effort of 92 1-3 lbs. per ton (2000 lbs.) will produce an acceleration of 1 mile an hour per second on a level track, and the rate of acceleration will vary in direct proportion to the amount of tractive effort used. On the ordinary street car the tractive effort during acceleration often rises to between 200 lbs. and 300 lbs. per ton. In elevated or suburban train service the maximum tractive effort is generally from 100 lbs. to 150 lbs. per ton, while for heavy freight work where slow speeds are used, it may not exceed 30 lbs. or 40 lbs.

Grades are commonly expressed in percentage of feet rise in a length of 100 ft. and the tractive effort required

for a grade is the same percentage of the weight as the rise in feet is to a length of 100 ft. For instance, a 3 per cent grade will require a tractive effort equal to 3 per cent of one ton, or 60 lbs. per ton. To this figure must be added the tractive effort necessary to overcome the car friction, if the total tractive effort is required.

The car friction necessary to overcome the rolling friction of the rail and air resistance has been compiled from a number of tests and the approximate amounts are given in the following table:

Fifteen-ton car, up to 25 miles per hour, tractive effort equals 25 lbs. per ton.

Fifteen-ton car, up to 50 miles per hour, tractive effort equals 50 lbs. per ton.

Twenty-five-ton car, up to 25 miles per hour, tractive effort equals 20 lbs. per ton.

Twenty-five-ton car, up to 50 miles per hour, tractive effort equals 25 lbs. per ton.

One hundred-ton train, up to 25 miles per hour, tractive effort equals 15 lbs. per ton.

Heavy freight train, up to 25 miles per hour, tractive effort equals 6 lbs. to 10 lbs. per ton.

The above figures would be considerably increased by presence of snow or dirt on the track.

TRACTIVE COEFFICIENT

This coefficient is usually expressed as the ratio between the weight on the driving wheels and the total tractive effort and is dependent upon the adhesion between wheels and rail. It has a variable value for the same equipment, being largely affected by the condition of the rails, whether wet, dry or sanded.

In train work, it may be stated as a general rule, that the weight on the driving wheels should be at least six times the tractive effort required. For example, the weight of a locomotive necessary to haul a 100-ton train up a 2 per cent grade would be found as follows:

100 × 15 lbs. friction = 1500 lbs. for friction of train,
100 × 40 lbs. for grade = 4000 lbs. for grade,
Total tractive effort required, 5500 lbs. for train only.
Assuming a 20-ton locomotive, we have:
20 × 15 lbs. for friction, = 300 lbs.
20 × 40 lbs. for grade, = 800 lbs.
Total tractive effort for locomotive only, 1100 lbs.
Total tractive effort for train, 5500 lbs.
Total, 6600 lbs.

This is 16.5 per cent of 20 tons, the weight of the locomotive, it being assumed that all axles on the locomotive are equipped with motors and the entire weight is, therefore, available for traction.

Starting this train on the 2 per cent grade, assuming the slow accelerating rate of one-third of a mile an hour per second, would require an additional tractive effort of $\frac{92.3}{3}$ = 30.8 lbs. per ton, a total of 11,543 lbs. This would necessitate using a 35-ton locomotive and the total tractive effort in this case is 16.8 per cent of the weight of the locomotive, or 35 tons.

The following table is based on the results of a series of tests and shows, in a general way, the variation in the tractive coefficient under different conditions:

TRACTIVE COEFFICIENT

	Per cent	Sanded, Per cent
Dry rail	28	28
Thoroughly wet rail	20	25
Greasy moist rail	15	25

With ice or snow on the rails the coefficient may be even lower, while the rolling friction at the same time may be largely increased on account of the snow. With this fact in mind the value of four-motor equipments, even for single cars, is evident, especially on suburban service where the cars run through an open country exposed to snow and ice.

AVERAGE ENERGY

To approximate the capacity of the power station for any given service the average energy required may be assumed as 100 watt hours per ton mile of schedule speed. As an example, assume a schedule speed of 12 miles per hour and a car weighing 15 tons. The average kilowatt rate of energy consumption per car would be
100 watt hrs. × 15 tons × 12 m.p.h. = 18,000 watts = 18 kw.

The figure of 100 watt hours per ton mile of schedule speed is generally correct for the ordinary conditions of city and suburban service. If the stops are a mile or more apart, the energy consumption may be as low as 60 watt hours or 70 watt hours, while frequent stops and very high schedule speeds may increase this figure to 120 watt hours or even more.

The Westinghouse Electro-Pneumatic System for Controlling Railway and Other Motors

It is a well known fact that under certain conditions in electric train operation, important advantages arise in the ability to simultaneously control, from either end of a train, all the motors of the several cars of a train. This problem has been undertaken by Geo. Westinghouse, who has invented and personally developed, at the works of the Westinghouse Air Brake Company, at Wilmerding, near Pittsburgh, Pa., an electro-pneumatic system of motor control. This system is covered by United States and foreign patents, which have been granted to Mr. Westinghouse, and involves the use of compressed air for moving the controlling apparatus, the admission of the air to the several parts being effected electrically by means of magnets attached to the air valves. The reliability of pneumatically operated apparatus has been demonstrated by years of service in railway work. In fact, the air-transmitting and applying apparatus, and the electro-magnetic devices employed in this system of control are standard parts manufactured respectively by the Westinghouse Air Brake Company and the Union Switch & Signal Company. In this respect the Westinghouse method will possess in advance the confidence of railway managers who have had experience with the use of these appliances.

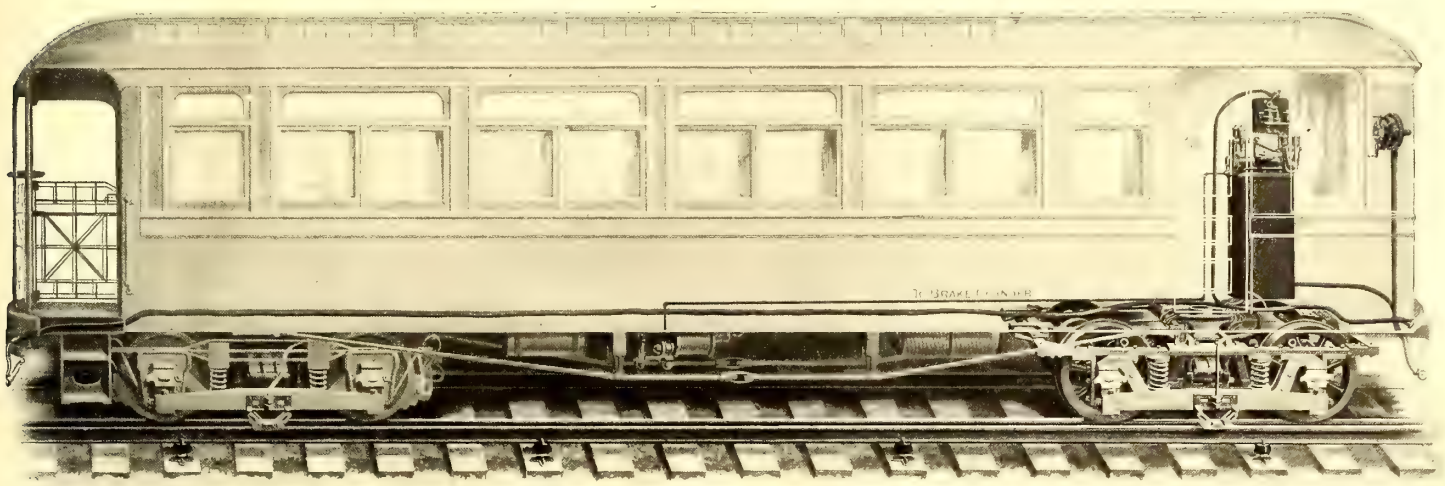

FIG. 1.—CAR EQUIPPED WITH ELECTRO-PNEUMATIC SYSTEM OF CONTROL

FIG. 2.—TRAIN OF CARS AT PITTSBURGH, FITTED WITH ELECTRO-PNEUMATIC SYSTEM OF CONTROL

This system is adapted for use on any number of motor cars per train. Each motor car requires the usual current collecting and controlling devices. A full complement of air compressing and

storage apparatus is employed on at least one car, and auxiliary storage apparatus on each motor car.

The controller proper may be of any standard type designed for railroad work. Instead of the usual hand lever, however, a pneumatic operating mechanism is used, which may be adapted to any form or design of controller. The automatic circuit breaker in connection with each controller may also be of a standard type, and is provided with an operating device similar to that for the controller.

The air is taken from the reservoir which supplies the brakes, and the electric current for operating the magnets is obtained from a small primary or secondary battery. The operation of the controlling apparatus is therefore independent of the power circuit, except in so far as the reservoir is periodically charged by the motor-driven pump, receiving current from the power circuit.

The devices for operating the controller and circuit breaker do the work which normally devolves upon the motorman with the ordinary system of hand control and in precisely the same way, i. e., the controller is moved from notch to notch at the will of the operator. The controller, therefore, may be placed upon any notch and kept there as long as desired, and the movement over a complete cycle may be made either slowly or quickly, as the condition of the rails, load, grades, etc., may require.

A general idea of the construction of the apparatus used can be secured from the accompanying engravings.

Upon the extended end of the shaft of the main operating drum of the controller, in place of the handle, are mounted two ratchet wheels and a pinion, as shown in Figs. 3 and 4. Upon the top of the controller frame are mounted two air cylinders. The shorter of these two cylinders contains the piston for operating the pawls, which engage in ratchet wheels. The piston rod of the longer cylinder is provided with a rack which meshes with the pinion. Both of these cylinders are single acting, and are so mounted as to produce opposite direction of rotation of the controlling drum. To the upper part of the cylinders are attached the iron-clad magnets for operating the air valves.

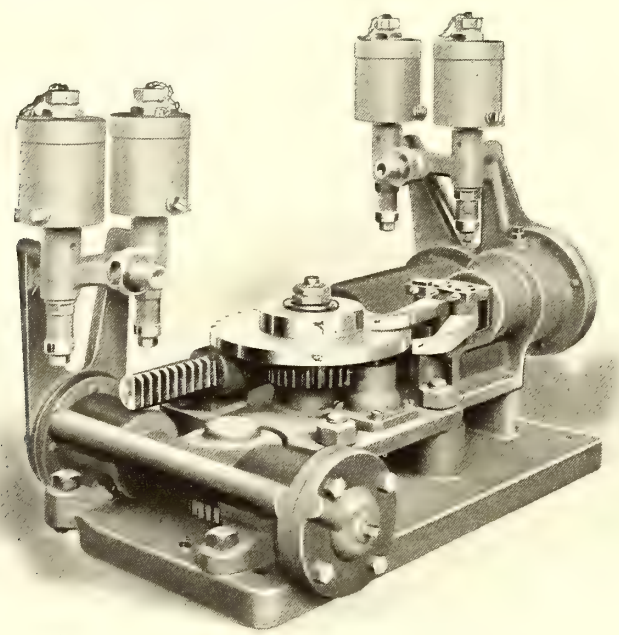

FIG. 3.—PNEUMATIC MECHANISM ON TOP OF CONTROLLER

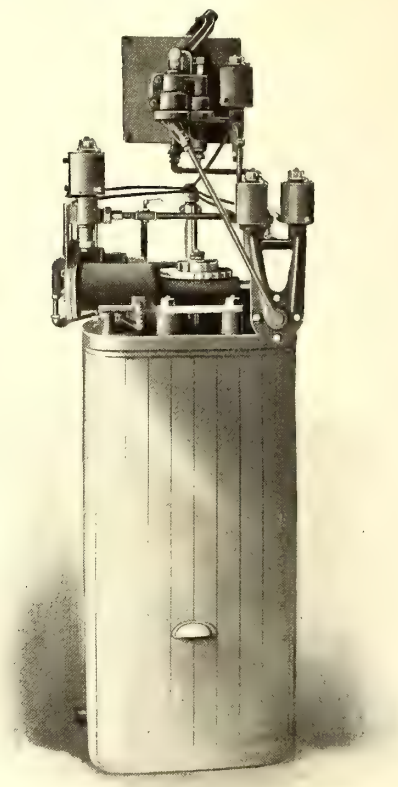

FIG. 4.—COMPLETE CONTROLLER

A single stroke of the ratchet piston turns the controller "on" one point, hence this piston must make as many strokes in turning the controller "full on," as there are operating points or notches. Two pawls and ratchet wheels are employed only in cases where movement steps of different lengths are desired. In such cases simplicity and certainty of operation are insured by employing ratchet wheels of different diameters and actuating them by pawls having an invariable stroke.

To prevent the inertia of the controller drum from carrying it further than is intended with any given impulse, the ratchet wheel is provided on the under side with a series of projections. A stop attached to the frame is made to successively engage the several projections by the air pressure in the cylinder which operates the pawls. Hence, whenever air is admitted to the operating cylinder, the stop is brought into position by the time the pawls have completed their stroke and the controller drum is thus prevented from turning too far.

When air is admitted to the long cylinder, the piston is forced to the end of its stroke, which throws the controller to "off" position. The action of this cylinder is independent of the position of the controller at the time the air is admitted, the piston making either a full stroke, or a part of a stroke, depending upon the position of the controller.

The shaft of the reverse switch is also extended above the controller top and carries a pinion. The rack which engages the pinion is formed on a piston rod having at each end a small piston, which works in a corresponding cylinder. Upon one of these cylinders are mounted two magnets and the necessary valves for controlling the admission of air through suitable ports to either of the two cylinders. Air admitted into one cylinder will set the reverse switch in the position for giving a forward movement to the car, and when admitted into the other cylinder will set the reverse switch for a backward movement of the car.

The mechanical interlocking device of the standard controller serves to prevent the motorman from reversing the controller with the current on.

The circuit breaker is of the usual canopy type, for opening the circuit either automatically through the action of an excess of current or by hand. This circuit breaker is provided with two cylinders having pistons and rods arranged to act upon a lever for closing and opening the circuit breaker. The larger of the two cylinders is for closing the circuit breaker and receives air from the reversing switch cylinders on the controller. When the air is admitted to either of the reversing switch cylinders, air is also supplied to the closing cylinder of the circuit breaker. The smaller cylinder on the circuit breaker is for opening the circuit, the air being suplied to this cylinder by means of a magnet and valve similar to those used on the controller.

The details of the electro-magnets for operating air valves are carefully worked out. The coil is imbedded between an iron core and an iron shell, and the armature, which consists of a circular iron disc, partially completes the magnetic circuit between the upper ends of the core and shell. A suitable air gap is maintained by means of a spring washer bearing against the armature. When the circuit is closed, the armature is attracted, compressing the

spring washer and opening the air valve below the magnet by means of a brass rod attached to the armature. The valve is provided with a spring for keeping it normally in the closed position.

These magnets require but one-twentieth of an ampere at 6 to 8 volts. A battery of ten or twelve cells is sufficient for a train of five cars and will last a long time. Each motor car is provided with one of these batteries.

The controller and circuit breaker may be mounted anywhere on the motor car, but should be placed in an accessible place on account of inspection and repairs. For this reason it is always preferable to place the controller in the motorman's compartment or in a special compartment provided for the purpose.

To operate the controlling apparatus of each motor car of a train, from any specified place on the train (say either end of any motor car), a multiple control switch is required. With this switch the motorman makes or breaks the electric circuit from the battery through the several air valve magnets on all the cars of the train.

The multiple control switch, Fig. 5, consists of a cylindrical metal box provided with three handles and contains the several switches in circuit with the controlling magnets. The lower handle, shown in the illustration, controls the circuits to the magnets supplying air to the main operating and release cylinders on the controller. This handle is removable and designed to close the main battery circuit leading to all the switches contained in the box, when the handle is in place, and to open this circuit when the handle is removed; hence it is impossible to operate any part of the controller when this handle is removed from the box.

A single movement of this handle to the right closes the circuit to the magnet of the operating cylinder, which admits air and turns the controller "on" one notch. The position of the controller is indicated by the position of the index on the face of the box. It is, therefore, necessary to move this handle to the right and back to the middle position as many times as there are notches of operating points on the controller in order to move the controller to the full speed running position. To release the controller, this handle must be turned to the left, thereby closing the circuit to the magnet of the release cylinder. The magnet circuit is not opened by bringing the handle back to the middle position, but when the controller is fully released, air from the release cylinder is delivered through a suitable pipe to a small cylinder and piston in the multiple control switch, whereby the magnet circuit is opened, and the index on the face of the box turned to the "off" position. The air is not admitted to this cylinder until the release cylinder on the controller has completed its stroke, i. e., until the controller has entirely shut off the power from the motors.

The upper handle, shown in the cut, is for operating the reverse switch of the controller. To give a forward movement to the car, this handle is turned to the right slightly beyond the position shown. This closes the battery circuit through the magnet, which operates the valve supplying air to one of the reversing cylinders on the controller. To give a backward movement to the car, the handle is turned to the left. This similarly admits air to the other reversing cylinder on the controller. The handle will remain in either position, thereby indicating the direction in which the car will move.

The small handle at the right side of the box is attached to a cut-out switch, whereby a part of the controllers on the train may be cut out of service. When the handle is thrown upward to its extreme position, the motor car upon which the box is mounted is in service, the other motor cars being out of service; when the handle is thrown downward to the extreme position the motor car upon which the box is mounted is out of service, and the other motor cars are doing the work; and when the handle is placed in the middle position, all the motor cars of the train are in service.

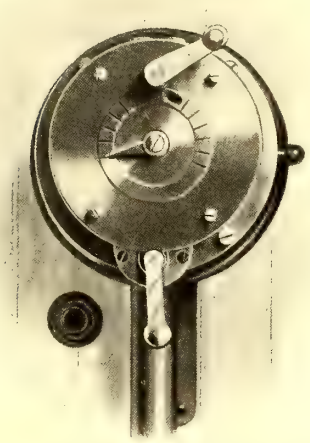

FIG. 5.—MULTIPLE CONTROL SWITCH

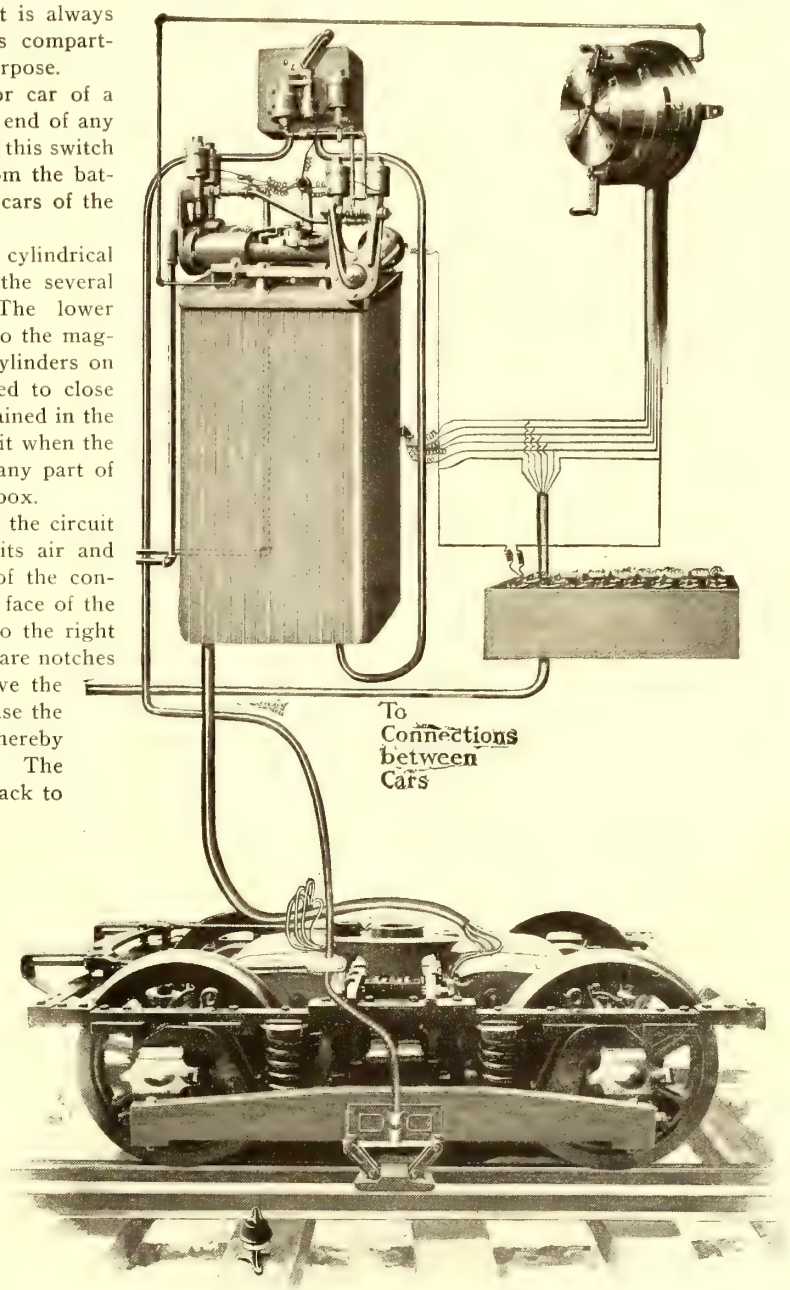

FIG. 6.—ARRANGEMENT OF CAB CONNECTIONS

The multiple control switch is mounted on a wooden base provided with sockets, in which plugs on the back of the switch engage. All parts are made interchangeable, so that any switch can be mounted on any back, the electric and air connections being permanently made to the base, and the connections with the switch made through the plugs and sockets. In this way a switch can be dismounted by simply removing four screws without disturbing the permanent wire or pipe connections.

A simple push button is mounted near the multiple control switch for opening the circuit breaker when desired. This simply closes the battery circuit through the tripping magnet on the circuit breaker.

An ingenious emergency device is also provided in connection

with this system. This consists of an air connection between the automatic air brake cylinder and the release cylinder on the controller. This is so arranged that whenever the air brake is applied the controller will be released by the air pressure from the brake cylinder, if this has not already been done by the operator. Such a device is of great value in case of accident or other contingency requiring emergency application of the air brakes, since it is not necessary to first release the controller before applying the brakes, but a single movement of the brake valve serves to open the motor circuit by effecting the return of the controller drum to the "off" position, and at the same time to apply the brakes.

It is also readily seen that this system of electro-pneumatic control may easily be adapted to other features of train operation, such as opening and closing ventilators, operating whistles and bells as signals or sanding track rails for traction. With motors on several cars of a train there is a special demand for such a means of sanding the track rails. This feature, as already developed in the cars now in operation at Pittsburgh, involves the use of a pneumatic sanding device, whereby an air jet is used for delivering the sand upon the track in front of the wheels, the supply of air being controlled by means of magnets similar to those used on the motor controlling apparatus, and an additional circuit passing through the train.

As an additional safety precaution, a device may be attached to the operating handle of the multiple control switch which will throw this handle to the release position and shut off the power from the train when the motorman removes his hand from the handle. A similar device may be attached to the handle of the brake valve, whereby the brakes will be applied and the power also shut off at the controller when the motorman removes his hand from the handle of the brake valve.

A diagram of the complete system for two cars with all connections is given in Fig. 7. In this, 1 is the controller; 2, the operating air cylinder for turning the controller in a forward direction; 3, the cylinder for turning it in a reverse direction; 4, the reservoir; 5, multiple controlling switch; 6, the rotary compressor; 7, the motor for operating the compressor; 8, the engineer's brake valve; 9, the main circuit breaker; 10, the air brake cylinder; 11, the circuit breaker for the compressor motor circuit.

When this system of control is applied to elevated railways the best results may often be obtained by equipping only the front and rear cars of each train. The number of motor cars required to operate a given road may be thus kept at a reasonable minimum and a considerable amount of time and cost of operation saved by thus abolishing the necessity of shunting and relaying motor cars at terminal stations. The number of cars per train may be varied by changing the number of ordinary cars between the two motor cars, this being accomplished with but slightly more effort than that involved in adding trailers to the end of a train.

Where this method of operating trains is adopted, it is necessary to provide the controlling apparatus for motors and air brakes at one end of each motor car only, that end being always either the leading or trailing end of the train. In this way a larger compartment can generally be provided for the motorman, in which may be installed, not only the operating apparatus, but also the controller proper, the circuit breaker and the air compressor, with necessary reservoir and accessory apparatus.

The advantages of the quick acting automatic air brake, manufactured by the Westinghouse Air Brake Company, are so well known to railway men as to scarcely need mention here. As an emergency brake in case of accident, it is especially valuable on account of its quick operation. There is also a great saving in the time required in making ordinary service stops, particularly in cases where it is necessary to bring the train to a stop with accuracy at a certain point of the station platform. Under such conditions trains in daily service, equipped with the automatic air brake, are being stopped from a speed of 30 miles per hour, in a distance of 400 ft. to 500 ft.; and from 20 miles an hour, in 275 ft. to 300 ft. With the Westinghouse air brake and the Westinghouse electro-pneumatic system of control, dangerous results from a train "breaking in two" are also entirely eliminated. When the cars part the air connection is broken, causing an emergency application of the brakes on both sections of the train. This in turn shuts off the power by means of the pneumatic connection between brake cylinders and controller, releasing the cylinders described above.

Another interesting and novel feature of the Westinghouse electro-pneumatic system of control is the compressor used. As is well known, all motor-driven air pumps, heretofore, have been of the reciprocating type, involving the use of gears. The Westinghouse pump, used with the equipment mentioned above, is of the compound rotary type, and consists essentially of a drum mounted eccentrically in a cylinder, and provided with radically moving pistons or piston slides, according to the usual rotary

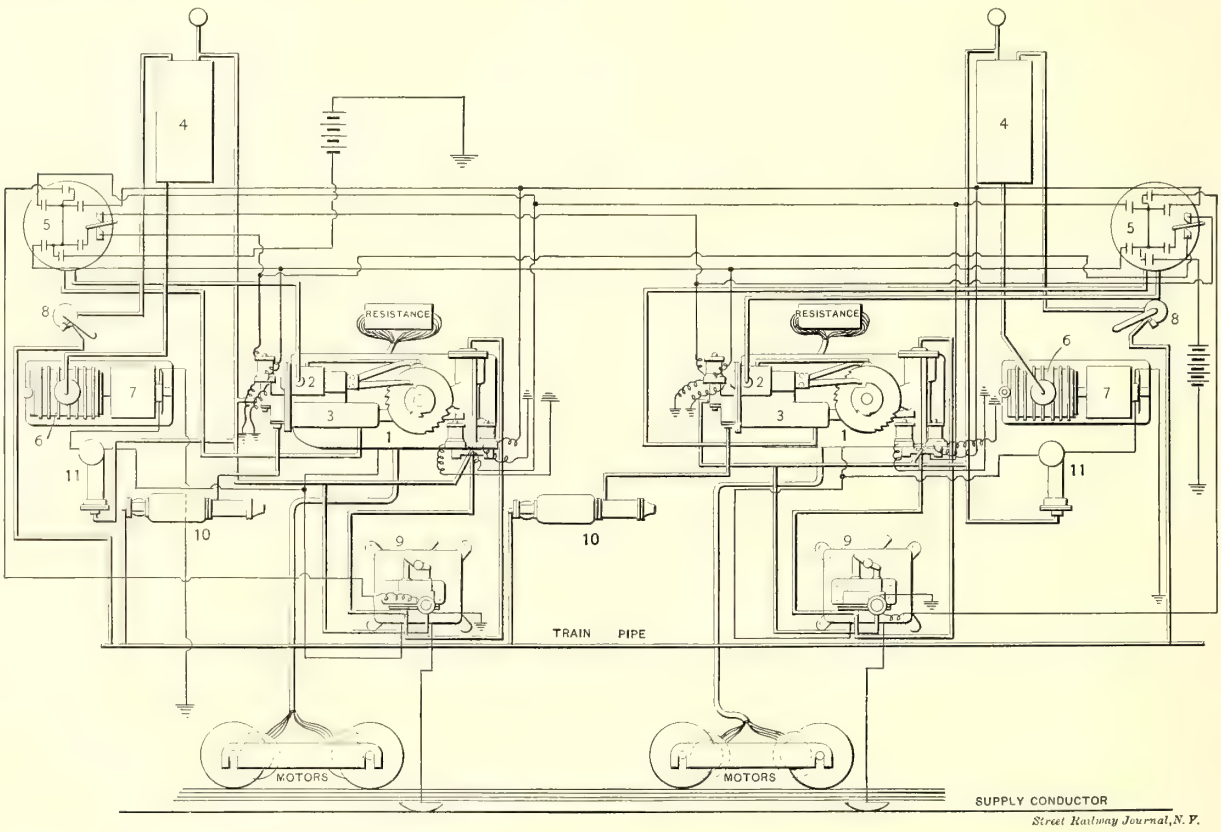

FIG. 7.—DIAGRAMMATIC VIEW OF ALL ELECTRIC AND PNEUMATIC CONNECTIONS ON TWO-MOTOR CARS

pump and engine practice. Mr. Westinghouse, however, has also introduced what is termed a balancing ring, for reducing the friction between the moving piston slides and the inner surface of the cylinder, as well as means for injecting oil at different points and pressures for lubricating and packing purposes. The armature of the driving motor is mounted directly on the pump shaft, and the whole outfit is compact and substantial in construction. These pumps, which are illustrated in this connection, are giving marked satisfaction in all places where they have been installed.

A fully equipped elevated railway train, designed as a model for

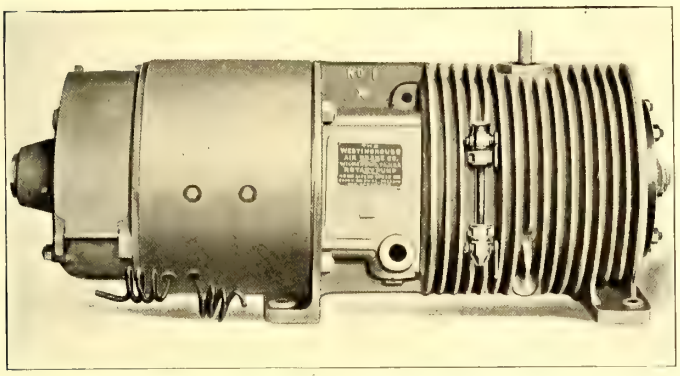

FIG. 8.—MOTOR AND ROTARY AIR COMPRESSOR

such service, is also in operation upon the experimental tracks between the factories of the Westinghouse Electric & Manufacturing Company, at East Pittsburgh, and the Westinghouse Air Brake Company, at Wilmerding, Pa.

This train is operated by two motor cars designed with special reference to the requirements of electric traction on elevated structures. Each motor car is equipped with two 150-h.p. Westinghouse motors, mounted on the same truck, which is placed under the front end of the motor car.

The trucks, which are illustrated in Figs. 9 and 10, have been specially designed for heavy electric railway service of this kind by the Baldwin Locomotive Works, and have a number of special features. As will be seen, they are very similar in general features to the standard M. C. B. truck, but vary somewhat to fit them for electric railway service. The main points considered in their design were simplicity of arrangement and facility of inspecting and removing the motors. By removing four thimble bolts under the pedestal and by disconnecting the motor cables the entire upper half of the truck can be removed from the lower part, as shown in Fig. 10. This leaves the axle, motors and side suspension bars entirely exposed, so that they can be easily inspected.

It will also be noticed that the motor spring suspension is entirely separate from the car spring system, the motor being supported on separate side bars, as shown in Fig. 10. This enables the traffic manager to graduate the system of springs supporting the car body to any extent desired, making a very easy riding car. The dimensions of the truck illustrated are as follows:

Wheel base, 6 ft.
Diameter of wheels, 36 ins.
Kind of wheel, steel tired with wrought iron spoke centers.
Axles, best hammered iron.
Diameter of axle center, 6½ ins.
Diameter of axle gear seat, 7½ ins.
Diameter of axle wheel seat, 7½ ins.
Journals, 4¼ ins. x 8 ins.

Another novel feature of the truck is that the gears are pressed on to the axles and keyed. This practice of pressing the gears on the axles was followed to avoid any possible weakness in split gears which might develop in transmission of the large amount of power required in equipments of this kind. In fact, it is claimed that it is practically impossible to make a split gear of sufficient size to accommodate the proper number of bolts to hold the two halves together. To press the gear off it is, of course, necessary to first remove the wheel and afterward press it on again. This can be done, however, several times without destroying the fit. As two gears will probably outwear one axle, this operation, however, will occur only once in the life of an axle. The weight of the motor truck, complete with special suspensions described, but without motors, is 10,000 lbs.

Mention should also be made of the construction of the motor end of the cars, which is of special type, to secure plenty of room above the motors without elevating the car floor more than was absolutely necessary. The floor framing at the end over the truck carrying the motors is covered with ½-in. steel plate, extending from the end sill to the inner end of the truck. The center sills of the car are two 4-in. I beams extending the entire length of the car, and the side sills are 3½-in. x 8-in. wood, reinforced on the inside by 6-in. channels. This method of construction makes an exceedingly strong car end and provides the maximum amount of room underneath the floor of the motors and trucks with any given height of car platform. The standard height of an elevated car platform is 42 ins. above the rail, and with this construction of car this height can be maintained, when using the largest size of motor which can be designed for a standard gage track. These cars were built by theWason Manufacturing Company, of Springfield.

The weight of the motor car, as equipped at East Pittsburgh, having two 150-h.p. motors on one truck and a trail truck at the other end of car, is:

	Motor Truck End	Trail Truck End
Light weight	41,000 lbs.	19,500 lbs.
Loaded weight (90 passengers at 140 lbs.)	47,000 lbs.	26,500 lbs.
Total weight loaded car	73,500 lbs.	

The motors are designed especially for elevated and suburban railway service. A new type of suspension is used whereby the motors are supported through suitable springs from the axles of the truck, and not from the frame of the truck. With this arrangement the truck springs are designed to carry the car body only, thereby obtaining as good riding conditions as can be secured on any ordinary passenger car.

In the front end sill of each motor car is inserted a Westinghouse friction buffer, securely anchored to the steel framing. This buffer comes into use in times of collision only, and is completely compressed with only 100 tons pressure, and has a travel of 2¼ ins.

The motorman's compartment occupies the entire end of the

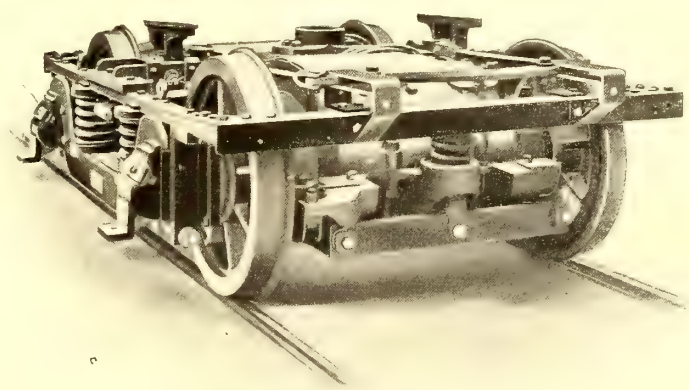

FIG. 9.—END VIEW OF TRUCK

motor car, and is separated from the passenger section of the motor car by a heavy partition, placed just in front of the center line of truck. A door is provided on each side of the passenger section, next to this partition, for the ingress and egress of passengers. The compartment contains the controller, circuit breaker and multiple control switch; also the rotary air compressor, with direct connected motor and main reservoir, and the motorman's valve for controlling the automatic air brakes. This arrangement brings all the accessory parts of the apparatus together in a place where the motorman can easily inspect them, and where the parts can readily be cleaned and repaired.

The resistance used in connection with the standard controller is mounted underneath the car body, and all the wiring is enclosed in iron armored conduits. Sand boxes are placed under the seats of the car, and the electro-pneumatic system of applying the sand to the rails is used. The cars are also equipped with electric heaters placed under the car seats, and with electric lights distributed above the windows along both sides of the car.

Suitable contact shoes are provided for collecting the current from a third rail. The shoes are mounted on the motor cars only, and the heaters and lights on the trailers are supplied through suitable flexible connectors between the cars. One of these motor cars is used at each end of the train, the compartment end of the motor car being always either the leading or trailing end of train. Wires and connectors, already described, for simultaneously operating the controllers, circuit breakers and sanding devices on both motor cars from the compartment of either motor car, are also provided on all cars. Each of these motor cars, without passenger load, weighs about 60,000 lbs., the weight of the motor end being 41,000 lbs., and the other end 19,000 lbs.

Upon the same experimental road, between East Pittsburgh and Wilmerding, are also operated two very heavy motor cars, each equipped with four 150-h.p. motors, and two controllers operated by means of the Westinghouse electro-pneumatic system of control. These cars are also equipped with air pumps and quick action air brakes, and are constructed for operating heavy suburban trains, running at high speed and making frequent stops.

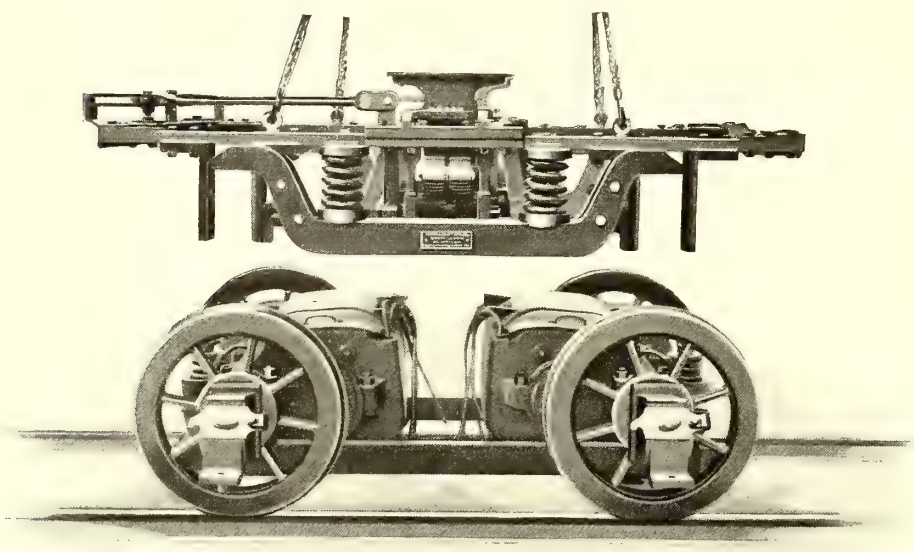

FIG. 10.—VIEW OF TRUCK WITH UPPER PART REMOVED, EXPOSING THE MOTORS FOR INSPECTION

By reason of the close business relations which obtain among the Westinghouse Companies and an existing working agreement with the Baldwin Locomotive Works, substantially all the parts of a complete equipment, except the car body, are manufactured by associated interests. It is, therefore, possible to provide a complete equipment, all the elements of which are designed to harmonize and properly co-operate with each other.

Telephones for Electric Traction Systems

The General Electric Company, Limited, of 39 Victoria Street, London, is making a large number of telephones for electric traction systems, and for this purpose has designed an instrument of an efficient type and yet one which occupies a minimum space, the latter being a most important requirement. In order to obtain this end, the instruments, while of the usual character, including microphone, receiver and induction coil, are so connected that in the boxes on the line poles no batteries are required. thus, at the outset, effecting not only a considerable saving of expense, but also a most important economy of space. All instruments to be installed in such places are thoroughly protected against any possible injury from the weather or damp. The internal connections having been made, the containing case is filled in solid with pitch, making a permanent and substantial job; the flexible cord between the telephone and containing case is well waxed, and then drawn through a thick rubber tubing. The microphone is absolutely watertight and could be submerged in water for many hours without injury, and the receiver has its coils surrounded by paraffine wax poured in in a molten condition.

A Large Manufacturer of Electrical Goods

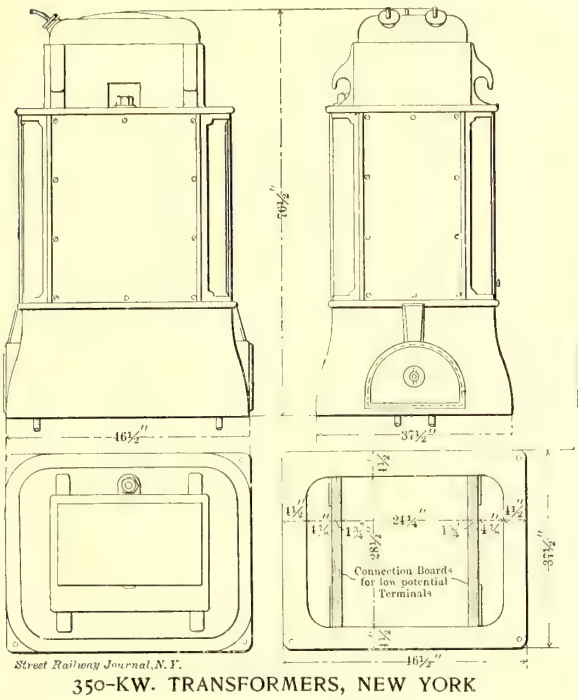
The American Steel & Wire Company, contrary to the impression which might be created by its name, is by no means confined to the production of iron and steel wires or their products. By the absorption of the Washburn-Moen Manufacturing Company the larger organization inherited one of the world's most important manufactories of bare and insulated copper wires in various forms and for all electrical purposes.

With the immense plant at Waukegan, Ill., only 35 miles north of Chicago, at which much of the copper wire is produced, the American Company enjoys exceptional facilities for catering to the wants of the trade in the West, giving, as it does, to this organization the same prestige in occupying the Western field that is enjoyed by the Washburn-Moen department at Worcester, Mass., in Eastern territory. These statements are made on the assumption that they will be news in the commercial and manufacturing world having been so numerous to many readers, the recent changes and kaleidscopic that many, even among the large users of their products, have not become familiar with the new scope of their operations.

In every line of production certain names come to stand out in bold relief as synonyms for some characteristics of excellence. In the production of electrical wire, bare and insulated, the introduction of improvements calculated to secure best results and in uniformity of excellence, no name has ever stood higher than that of Washburn-Moen. The merging of this company into the American Steel & Wire Company means simply that, with unlimited resources, continued investigation and improvements are assured in the production of all forms of electrical wires, rail bonds, etc.

At the Waukegan plant special attention is given to the manufacture of the well-known "extra BB," "BB" and "steel" telephone and telegraph wires and copper wires for electric lighting and street railway plants in all their various forms, and the system of tests at every stage of the manufacture of these goods is at once so unique and rigid that the high standard set for all the products of this company is always maintained. Purity, conductivity, tensile strength, finish and uniformity to gage, are all given due attention, resulting in the output of millions of pounds, distributed among all the nations of the earth in the operation of the great telephone, telegraph and electrical traction systems.

In the production of copper rail bonds, either solid or flexible, the prestige of the Washburn-Moen name has been added to, since the formation of the American Steel & Wire Company, and the output of solid and flexible "crown" bonds in a variety of patterns and for adjustment to the rails in various positions has been marvelous. This is equally true of the manufacture and sale of copper trolley wire, in which this company has earned a commanding position.



In the department of insulated wires, the entire line, including every form of magnet wire, office and annunciator wire, weatherproof wire, feeder wires, lead incased wires and cables, and submarine cables, is thoroughly covered, the rubber insulating, taping, braiding, lead incasing, armoring and weather-proofiing being carried on under the supervision of the most expert scientific skill and experience that can be secured.

The general offices of the company are located in "The Rookery," Chicago, with branch offices in New York, Worcester, St. Paul, St. Louis, Cleveland, Denver, San Francisco and other cities.

It is stated that the New London Street Railway Company contemplates extending its lines to Niantic.

Apparatus for Power Transmission in New York

Long distance power transmission systems for railway work, as a rule, involve the use of three distinct types of apparatus, i.e., an alternating current generator, preferably of the three-phase type, by which mechanical energy is converted into electrical energy of the desired potential and frequency; step-up transformers to raise the potential of the generated current to that most effective for transmission over the line, with similar step-down transformers at the sub-station for reducing the line potential; and rotary converters for transforming the multiphase alternating current into

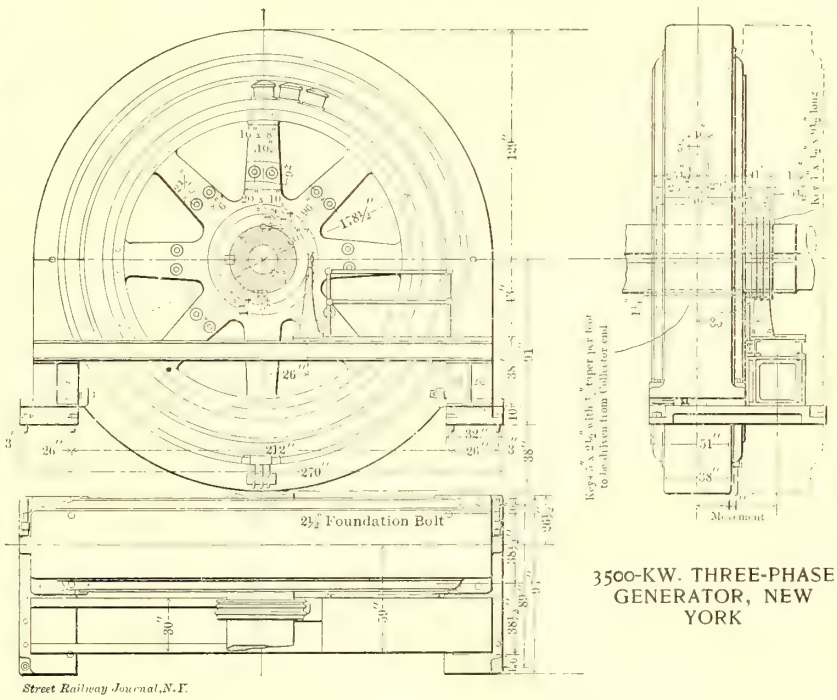
350-KW. TRANSFORMERS, NEW YORK

direct current of suitable voltage. In large systems where the distances are not so great as to demand an excessively high voltage, it is frequently found desirable to generate the current at the potential of the high tension transmission line, thus dispensing with step-up transformers and resulting in a simplification of the switchboard and wiring in addition to a considerable decrease in the initial cost of the plant.

A typical system of this character equipped with modern apparatus is that of the Metropolitan Street Railway Company, of New York City, now being installed by the General Electric Company. Some particulars of this station were published last month, and a map showing the location of the sub-stations was given.

The alternating current generators in this power station are of the revolving field type with external stationary armature, and are direct connected to Allis vertical compound engines. They have a normal capacity of 3500 kw., and generate three-phase current of 6600 volts at a frequency of 25 cycles and operate at a speed of 75 r.p.m. The internal revolving field ring carries forty poles, and is mounted directly on the engine shaft. The armature core is built up of soft sheet iron punchings, thoroughly japanned before assembling to prevent eddy current losses, and further insulated by sheets of paper inserted at suitable intervals.

The winding is placed in slots punched in the inner circumference, which are recessed for the insertion of wooden wedges to hold the winding firmly in place. The discs are firmly secured to the frame by dove-tailed projections fitted into corresponding recesses. Ventilating spaces properly placed allow a free circulation of air through the core in direct contact with the core and coils. The armature winding consists of separate coils accurately formed, and the construction is such as to allow any defective or burned out coil to be readily removed and replaced without disturbing more than a few adjacent coils. The coils are connected to the terminals by insulated conductors passing through holes in the projecting shields. After assembling, a high potential alternating current of 25,000 volts is applied to the winding for one minute.



The cast iron armature frame is arranged with sliding foundation plates, so that it may be moved to one side until clear of the revolving field, thus permitting access for inspection and repairs to both armature and field. The frame is made in sections, which are securely joined together by double-headed keys.

The revolving field is composed of a steel ring divided in the middle, the two parts being fastened together by double-headed keys. This ring carries the magnet poles and coils, which are securely bolted thereto, and is firmly bolted to the cast iron spider, which in turn is securely keyed to the engine shaft.

The field poles are built up of soft sheet iron punchings bolted together. The coils are wound of soft copper strips on edge, so that one side of the copper is exposed directly to the air. Each coil is thoroughly protected by insulating collars, and is held firmly in place by the projecting horns of the pole pieces. The e.m.f. required for exciting the field circuit is normally 125 volts.

The exciting collectors consist of two insulated iron rings, well insulated. These rings, as well as the supporting shield, are made in halves, so that they may be replaced in case of accident. Carbon brushes are used to carry the current.

The step-down transformers at the rotary converter sub-stations are rated at 350 kw., and are connected delta, each bank of three transformers being used to operate one rotary converter. By this method of connection one transformer may be cut out in case of accident, and the rotary converter operated at reduced output from the other two.

3500-KW. THREE-PHASE GENERATOR, NEW YORK

The primary winding of the transformer is designed for a potential of 6000 volts, and the secondary for 350 volts, the ratio of transformation being 17.15.

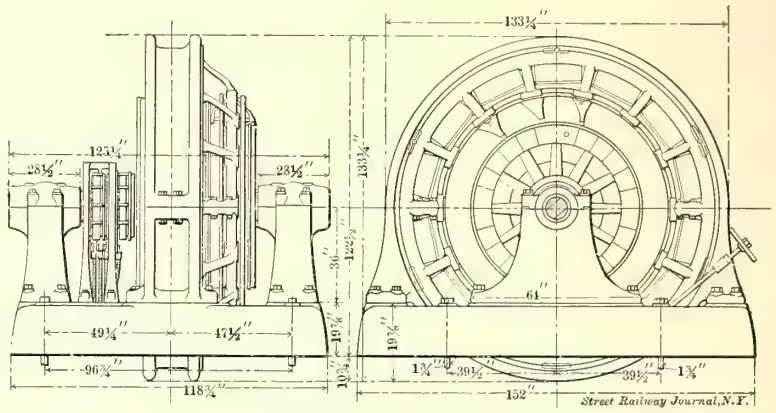
The transformers are of the air cooled type, and consist of flat primary and secondary coils placed vertically and surrounded by a built up iron core. The core of the transformer is bolted to a substantial cast iron base, and a cast iron cap or cover, and is enclosed in a sheet iron casing; one side of the casing forms an air chamber for the supply of air to the transformers, and the other side is perforated to allow the escape of the heated air. The low potential terminals are located in the base and the high potential in the cap. Register gates at the top and on one side of the transformer provide for the control of the air supply.

The core is built up of laminated iron sheets carefully annealed and insulated from each other in order to reduce eddy current

losses. The primary and secondary windings are subdivided into several coils, each built up of flat conductors wound with but one turn per layer, so as to form a thin and high coil. Each coil is thoroughly insulated with a continuous wrapping separately treated with a special insulating compound, so as to form together a very durable and moisture-proof insulation capable of resisting a potential stress much greater than that for which the transformer is wound.

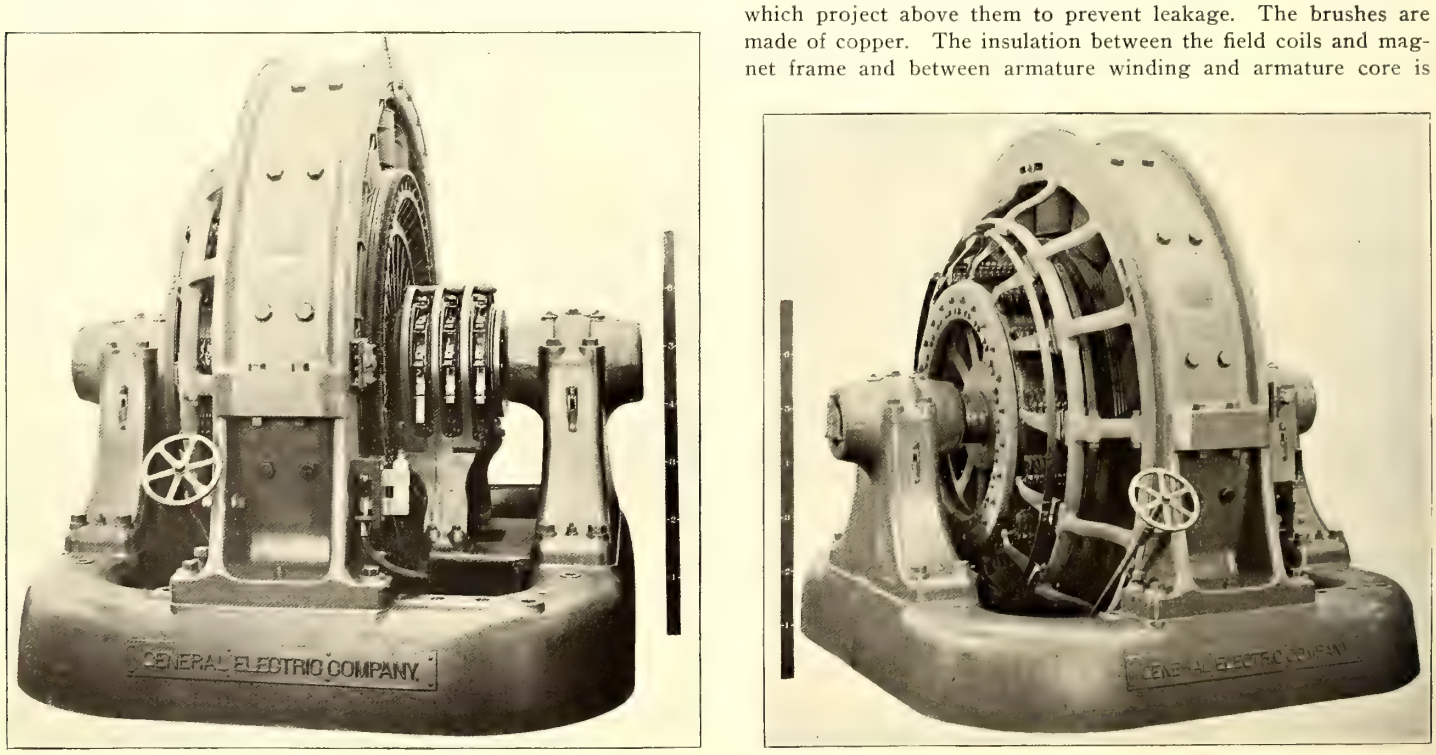
The conductor consists of a sufficient number of strands in both primary and secondary to effectually prevent any eddy current losses in the winding. A solid insulating diaphragm is rigidly held between the adjacent sections of the primary and secondary winding, so as to provide an air duct of equal width on each side. Frequent open spaces or ducts are also provided in the laminations so that air can be forced through the entire structure to maintain the low temperature necessary to avoid deterioration. The secondary terminals consist of substantial castings, into which the cables coming from the coils are sweated, and are provided with tapered holes suitably drilled for receiving the out-going cables. The primary terminals consist simply of cables with an approved form of union coupling for joining to the station wiring. This coupling is provided with a hard rubber insulating sleeve.

Before leaving the factory the insulation of each transformer is tested with an alternating e.m.f. of 12,000 volts between the primary winding and the core or case, and with volts between the secondary winding and other metallic parts of the transformer. The transformer has an efficiency at full load of 98.22 per cent.



The regulation at full non-inductive load is .97 per cent, and the core loss 3970 watts. Each transformer requires approximately 1150 cu. ft. of air per minute at a pressure of ⅝ oz. for purposes of cooling.

The rotary converters in the sub-station are of the revolving armature type provided with six collector rings at one end, and a direct current commutator at the other end. The machines are rated at 990 kw. at 550 volts. When supplied with the necessary six-phase alternating current at 25 cycles per second the speed of the rotary converter is 214 r.p.m.



The magnetic circuit consists of a circular cast iron yoke with eighteen inwardly projecting poles made of cast steel. The poles and field coils are made removable without disturbing either the armature or the magnetic yoke. The field coils are wound on malleable iron spools, and are insulated with veneer board and oiled cotton.

The armature is of the iron-clad or slotted core type, and is thoroughly ventilated by means of air ducts suitably spaced. The spider is of cast iron, and the laminations or punchings are keyed thereto in such a way that no bolts pass through the core. In order to prevent eddy currents in the core the laminations are thoroughly insulated by a coating of japan on each sheet.

The armature winding consists of copper bars laid in slots, and insulated from the armature core by means of alternate layers of oiled linen and paper. The commutator is supported on the extension of the armature spider in such a way as to entirely avoid any relative movement of armature winding and commutator segments. Commutator segments are made of hard-drawn copper, insulated by sheet mica. Collector rings of cast copper, supported by a cast iron shell, and insulated therefrom by mica rings, are provided to carry the three-phase alternating current from the low potential side of the transformer to the armature winding of the rotary converter. These rings are further insulated from each other by wooden rings, which project above them to prevent leakage. The brushes are made of copper. The insulation between the field coils and magnet frame and between armature winding and armature core is designed to stand an insulation test of 5000 volts alternating current.

990-KW. ROTARY CONVERTER

SIDE AND END VIEWS OF ROTARY CONVERTERS

The rotary converter was found in test to give the following efficiencies, including losses in commutator, brushes, bearings, core and winding as six-phase machines:

Double load	96.8 per cent
Full load	96.0 per cent
One-half load	93.6 per cent

The regulation in potential at the direct current end of the rotary converter is obtained by means of reactances having a volt-

ampere capacity of 5 per cent of the capacity of the converter. These reactances are connected partly in the low potential side of the static transformers at the sub-station and partly in the high potential circuit at the generating station, these latter reactances or choking coils being designed to reduce the current taken by the generators in case of a short circuit on the line. A series winding is provided to automatically vary the field charge so as to obtain the desired adjustment of potential at the direct current end.

As a precaution against excessive speed of the rotary converter, due to the direct current and a weakened field, a centrifugal switch is mounted on the rotary converter shaft, which will open the switch in a circuit normally energized, and trip the automatic circuit breaker through which the direct current must pass in the event of the speed exceeding 20 per cent above normal.

The rotary converters are started from the direct current end by means of current furnished by storage batteries. This method insures starting the rotary with the right polarity, thus avoiding possible delay, and enabling the machine to be more readily synchronized.

New Type of Compound Engine

The accompanying engravings show a new type of compound engine, manufactured by the Chandler & Taylor Company, of Indianapolis. The principles upon which this engine is based are novel and are intended to secure a high rate of engine economy on widely varying loads, a condition of the greatest importance in electric railway service where the load is constantly fluctuating. The system adopted to accomplish this result has been carefully worked out by Mr. Rites, the well-known inventor of the inertia governor, which has been widely adopted in steam engine construction.

The generally adopted methods of compounding the cylinders of small and medium-sized steam engines may be divided into two classes. The first method is to connect both the high-pressure valve and the low-pressure valve to one eccentric under the control of the shaft governor. The other is to control with the governor the valves of the high-pressure cylinder only, and connect the low-pressure valve to an eccentric fixed on the shaft. In the first method both valves have the same relative stroke or travel, and this travel varies with the load on the engine. The effect of this arrangement is to vary the steam pressure in the receiver between the high and low-pressure cylinders, causing a high receiver pressure on light loads and a low receiver pressure on heavy loads. The use of the second method has a precisely opposite effect, that is, while the receiver pressure varies with different loads the pressure is low with light loads and high with heavy loads. It will be seen that in either case a variation of load produces a variation in the pressure of the receiver, and the effect of this is inimical to the efficiency of the engine, first, because it varies the distribution of the load between the cylinders, and, second, because it produces a great variation in the temperatures of the steam in the low-pressure cylinder, thus wiping out the advantages gained in compounding. The device employed on the Chandler & Taylor compound engine is intended to avoid this trouble by equally dividing the work between the two cylinders whether the engine is heavily or lightly loaded, and to do this by operating the low pressure valves by a compromise method between the two already described, that is, the low-pressure valve is partly under the control of a fixed eccentric and partly under the governor, and just enough under the control of each to vary the cut-off of this valve for different loads in such a manner as to maintain the pressure in the receiver constant under all loads within the capacity of the engine.

The arrangement adopted is illustrated in Fig. 2. The rocker arm is shown at *A*, and is attached to the high-pressure eccentric rod *B*, which is under the control of the governor. The rocker arm carries a link *F*, the upper end of which is connected to the low-pressure rod *C*, which is attached to an eccentric fixed on the shaft. The high-pressure valve rod *D* is driven directly by the eccentric rod *B*, but the low-pressure valve rod *E* is connected to the middle of the link *F*. In this way it partakes of a motion intermediate to that which would be given by either *B* or *C*, and thus imparts to the low-pressure valve the required amount of travel to keep the pressure in the receiver at a constant in its relation to the initial pressure in the high-pressure cylinder.

While the system of steam distribution in this engine is a very important one, and has been given prominence on account of its new features, there are other points in addition to the method of

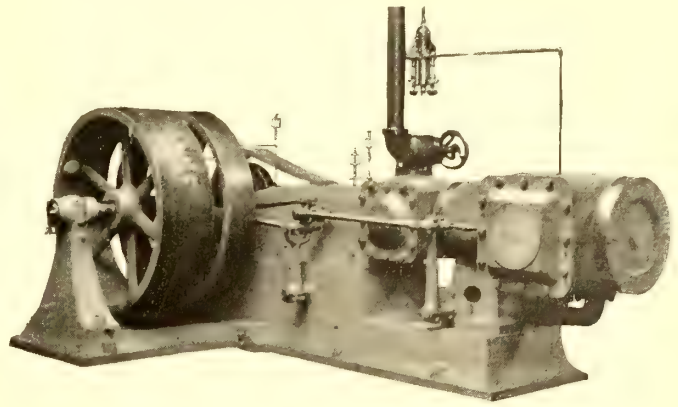


FIG. 1.—PERSPECTIVE VIEW OF ENGINE

compounding which merit attention. It is of a self-contained side crank type, mounted on a heavy sub-base which extends back into the distance piece to support the very heavy and substantial stand on which the distance piece is mounted. The arrangement of the cylinders is such that the pistons and rods can easily be withdrawn through the low-pressure cylinder without dismounting any part of the machine except the cylinder head. The pistons are threaded and the piston rods screwed into them, the piston rod being continuous from cross-head to the low-pressure

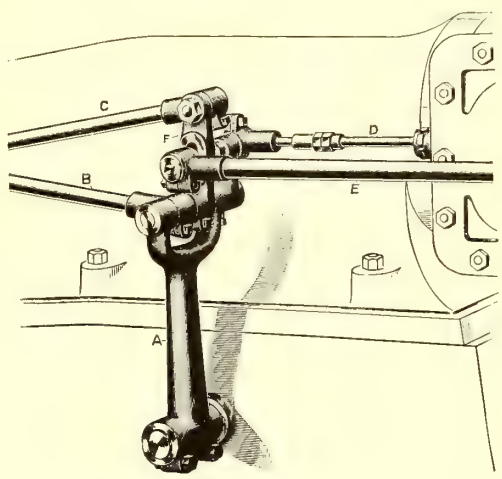

FIG. 2.—VALVE GEAR

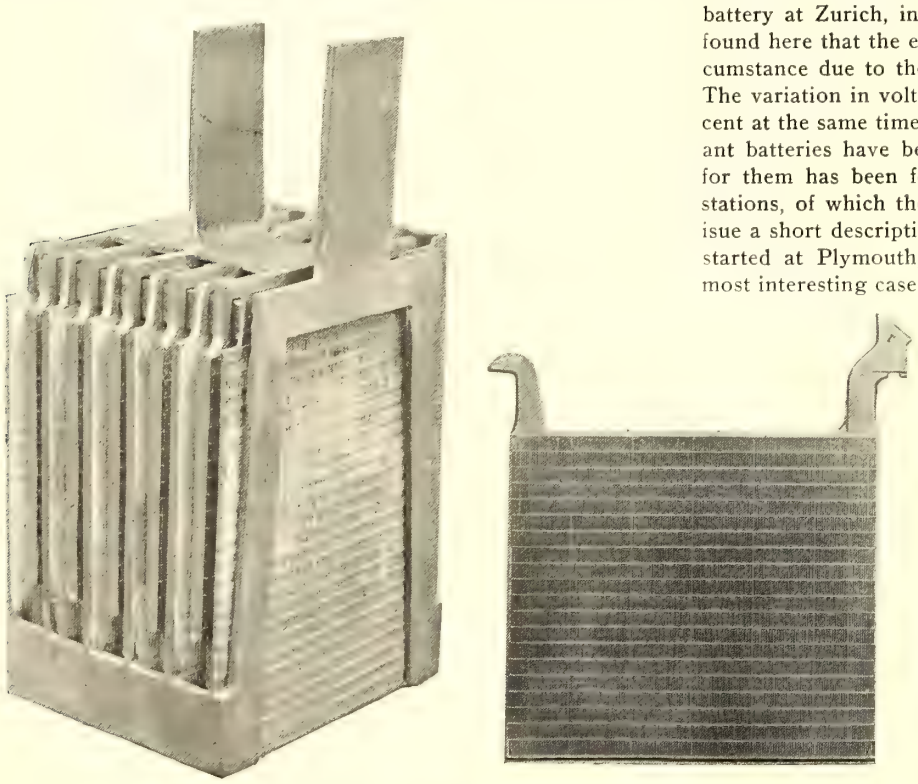
cylinder. The piston rod is held securely in the piston by lock nuts and set screws. The cross-head is screwed on the rod and held secure by a clamp nut. The connecting rod is a steel forging, mortised to receive the brass babbitt lined boxes. The governor is of the Rites type. All engines are thoroughly tested before shipment.

An Automobile Publication

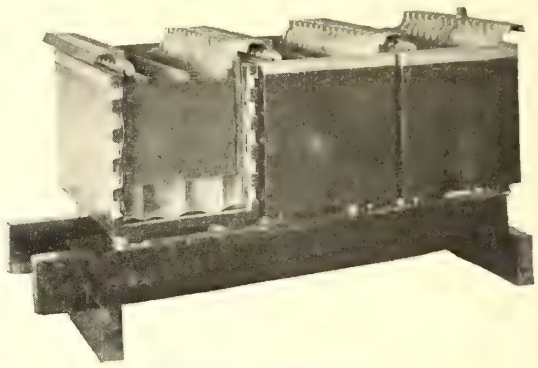


The E. L. Powers Company, of New York city, has issued No 1 of vol. 1 of a monthly periodical known as "The Automobile," and which will be devoted exclusively to the presentation in short concise articles of the latest information obtainable respecting the various uses of horseless carriages. Valuable points on the construction, operation and maintenance of these vehicles will be contained in each number.

Tudor Accumulators for Traction

The use of accumulators for electric traction may be divided under two headings: (1) stationary batteries at the generating or sub-stations, and (2) portable batteries on the cars or locomotives. It is very probable that in the future the use of accumulators in the first way will have a much wider application than the second, as though portable batteries have been very successfuly employed where trolley lines are not allowed or the traffic is insufficient for the capital outlay on the line, yet they can scarcely compete with the trolley in other cases.

The object of a stationary battery at the generating station is two-fold, it steadies the load on the engine under the varying outputs required on the line, and it helps over periods of heavy load, such as increased traffic, or in combined lighting and traction stations during lighting hours. Sub-station batteries, in addition, help to keep the voltage on the line steady at points distant from the generating station, in spite of the varying drop in volts. For all these purposes it is important to have a cell capable of withstanding high rates of charge and discharge, and of such cells it is an essential condition that they should be mechanically strong, and have Planté formed positive plates with large surface, so as to keep the current density per square inch as low as possible.



In the Tudor cells, which are now so largely used in traction stations in all countries, these points have been made a special feature; the positive plates are ½ in. thick, and are cast in one piece in a special mould, with fine vertical ribs to give a large surface, and stouter horizontal ribs at intervals to give the plate ample rigidity, as can be seen in the illustration. The surface is formed

TUDOR CELL AND SINGLE PLATE

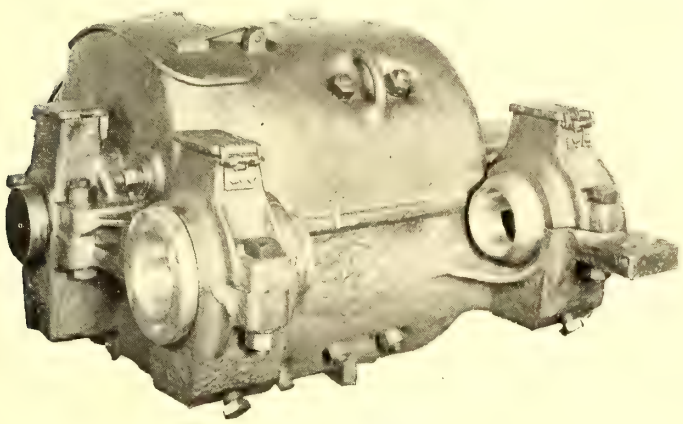
by the original Planté process, i. e., with sulphuric acid only; the process is a slow one, taking about six weeks, but the coating of peroxide of lead that is produced in this way is even, homogeneous and thoroughly adherent, which is often not the case when the process is hastened. Further, every detail of the Tudor cell has been carefully studied with a view to giving it the greatest possible mechanical strength; thus the plates are suspended from above so as to be always in tension, and they are burnt singly to a common connecting bar after erection, no screws whatever being used in any part of the batteries. All suspending sheets, separators, etc., are of glass, and no materials other than glass and lead are used inside the cells; a space equal to one-third of the depth of the plates is left for the accumulation of peroxide, and the cells require cleaning only at very rare intervals. The method of mounting is shown herewith. From these few details it will be seen that the Tudor cells combine both durability and solidity, and that the cost of their maintenance should be very low; that this is the case can be judged from the fact that they are maintained in good condition, and their full output guaranteed under contract at rates varying from 3 to 6 per cent of their cost.

A small point to which attention may be drawn is the usual way of mounting Tudor cells on stands that are insulated from the earth by porcelain oil insulators; these are in addition to the oil insulators under each cell, and when it is remembered that one

BATTERY OF THREE CELLS

pole of the battery is directly connected to the earth, and that comparatively high voltages are used, it will be seen that this detail has its importance.

Tudor batteries were first used for traction stations in 1892, a battery at Zurich, in Switzerland, being one of the first. It was found here that the effect on the coal bill was most marked, a circumstance due to the steadying effect on the load of the engine. The variation in voltage on the line was reduced from 12 to 4 per cent at the same time. Since then similar and much more important batteries have been put down everywhere, and a further use for them has been found in the combined lighting and traction stations, of which they are an important part. Elsewhere in this isue a short description is published of one of these stations lately started at Plymouth, where Tudor batteries are used. Another most interesting case may be found at Rome, where the generating plant is water power, and the tram cars are entirely driven by the batteries during lighting hours; the batteries here have a capacity of 3500 kw. hours, and are charged by rotaries from the alternating current lighting plant. Among other batteries of the same system for traction in the United Kingdom may be mentioned Southampton Corporation and Middlesborough Tramways, Brighton Seashore Lines and the City & South London and Hill of Howth (Ireland) electric railways; in the two last cases the batteries are placed in sub-stations to keep up the volts on the line.



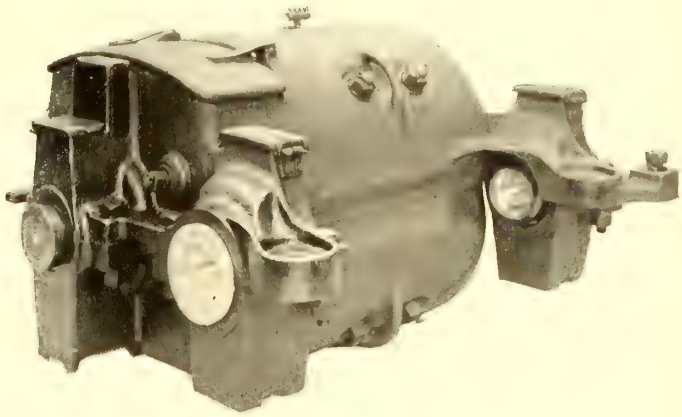
The second heading mentioned at the beginning of this article is too wide a subject to be discussed here at any length, but attention must be drawn to the novel way in which this problem has been attacked by the Tudor firms. Hitherto the two great obstacles to traction by portable cells on the cars have been weight and cost of maintenance. These two difficulties are closely linked together, as if the weight is reduced, the cell is less solid in construction, and, on the contrary, the most durable cells are the heaviest. The Tudor companies have availed themselves of the special capability of their cells to withstand high rates of discharge; they have kept their ordinary type of plate, of which the weight has been reduced as far as possible, but not so much as to compromise its durability. To reduce the weight of the battery, they only give it sufficient capacity for one trip, on the completion of which they charge it up without removing it from the car, in less than a quarter of an hour. A further development of this system is the combined battery and trolley line, where the battery runs the car in the center of a town, and is recharged at constant

potential from the trolley line when the car gets outside. Portable Tudor cells have now been in use in this way for over four years, and the results, both in working and costs, have everywhere been satisfactory. The main office of the Tudor Accumulator Company is at 16 Victoria Street, London.

New Types of Street Railway Motors

The Westinghouse Electric & Manufacturing Company has recently designed and will soon place upon the market five new types of electric railway motors ranging in size from 20 h.p. to 150 h.p. These, with the existing standard motors, supply a complete set of motors, from 20 h.p. to 150 h.p., designed for all conditions of railway service.

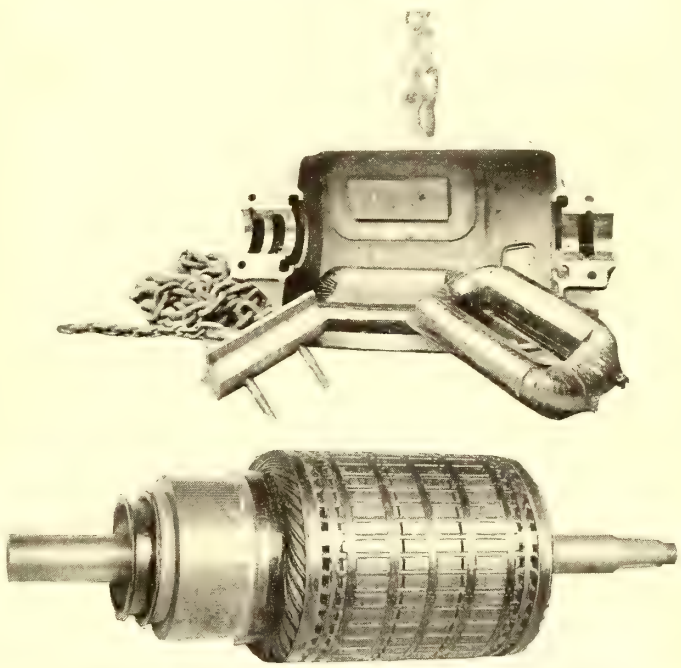
The new motors, which are graded according to capacity, are entitled No. 69, No. 68, No. 56, No. 70 and No. 50-C, are, in general, characterized by increased carrying capacity of the field winding, so that the temperature rise, resulting from continuous operation, will be the same in the field as in the armature. The use of laminated poles has been continued, but the poles are bolted to the yoke, rather than cast in, as has been heretofore the practice. The armature construction has also been modified somewhat, but particularly in the direction of securing the greatest possible ventilation, and, as will be described later, the core is



NO. 69 MOTOR

provided with air passages, and the coils are placed in the slots in such a manner that air spaces between them at their ends are secured. The following table gives the weights and gear ratios of these machines:

Name of Motor	No. 69	No. 68	No. 56	No. 70	No. 50-C
Total weight, lbs.....	1,951	2,261	2,968	4,792	5,200
Weight armature, lbs..	385	505	720	1,421	1,475
Gear ratio	64:18	64:18	64:18	70:18	52:19
	68:14	68:14	68:14	62:26	....
	....	....	58:24	52:36	....

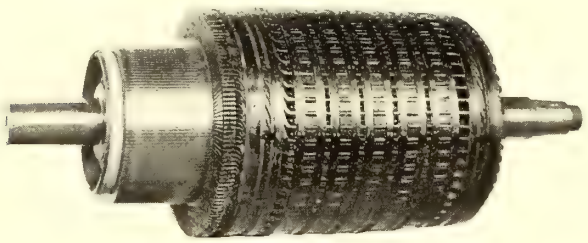


The No. 69 and No. 68 motors, which will be first discussed, are similar in general construction, but vary somewhat in capacity, the No. 69 motor being rated at 30 h.p. and the No. 68 motor at 40 h.p. They are fitted with removable laminated pole pieces bolted to the yoke, the coils being held in place by pole tips. The bolts which retain the poles do not pass through them, but terminate in a long nut inside the pole piece. The pole face, therefore, presents a smooth, unbroken surface, and the pole is perfectly rigid. The bearings are extra long and designed for either grease lubrication from above or oil lubrication from an oil wick at the side. In this position the oil can be inserted more easily than with a center wick, and the feed being between the gears, the pressure is the least at this point between the shaft and the bearing.

The motors are so designed that by removing the axle caps and the pin from the suspension link the motor can be lowered into a pit. Where this design of motor is used provision is made in the car barn or shop for a ram, or pit jack, in the pit, which lifts the motor into place on the car, or lowers the motor into the pit. With this equipment it is the practice to substitute one motor for another under the car, the new motor having been previously inspected and the old motor being laid aside for inspection the next day. Provision is made for hinging the upper field, so that it can be raised and inspection made while the motor is lying on the floor. In this manner a thorough inspection of all parts of the motor can be made with the greatest convenience, and the inspection does not have to be made at night or in a hurry, due to

NO. 56 MOTOR

the fact that the car must be in service again in the shortest possible time. It has also been demonstrated that the time for changing motors in this system is very much less than the time necessary for inspection of the motors underneath the car. Special provision is made for centering the motor on the head of the ram or jack referred to above. With a motor properly centered in this manner it can be raised to its exact position under the car, and no time is necessary for adjustment. The brush holders have adjustable coil springs, and the armatures have sunken bands and short-necked commutators. Three formed coils are placed in each slot. The motor is arranged for either cradle or nose suspension. While the method of dismounting and inspecting the interior is the quickest possible, it requires, as stated, the use of

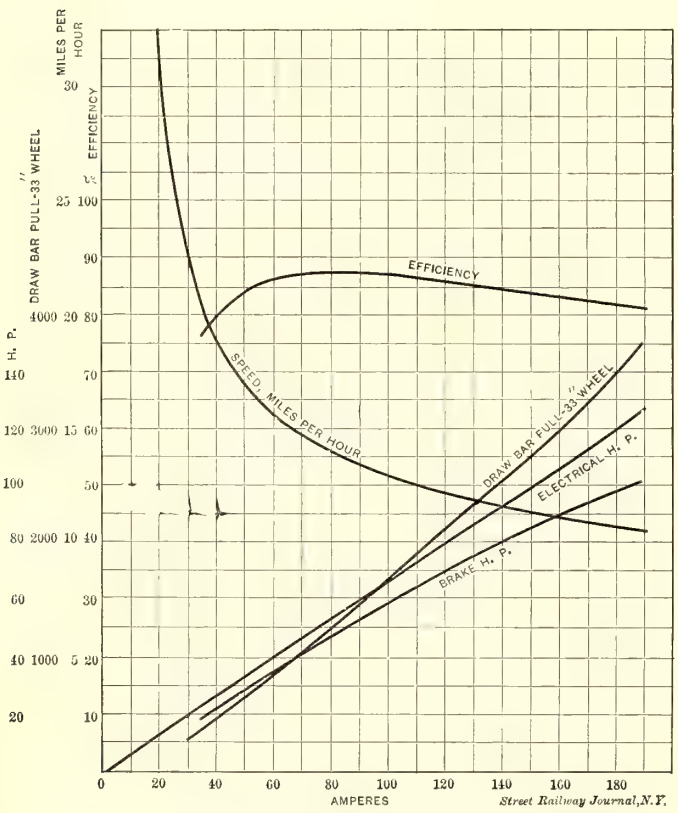


UPPER CASING AND ARMATURE OF NO. 56 MOTOR

a pit-jack, so that this motor will probably be most popular on those roads where the car house and repair shop facilities are quite complete. In other words, this motor is particularly for large roads, and is the one adopted by the Third Avenue Railroad Company, of New York, the North Jersey Traction Company and other large corporations.

These motors may also be furnished with the same style field as No. 56. The No. 56 motor is similar to the Westinghouse No. 68 motor, but 20 per cent to 25 per cent more powerful than the 38-B, and is intended for the heaviest city, suburban and interurban work. The pole pieces are removable, like those of the

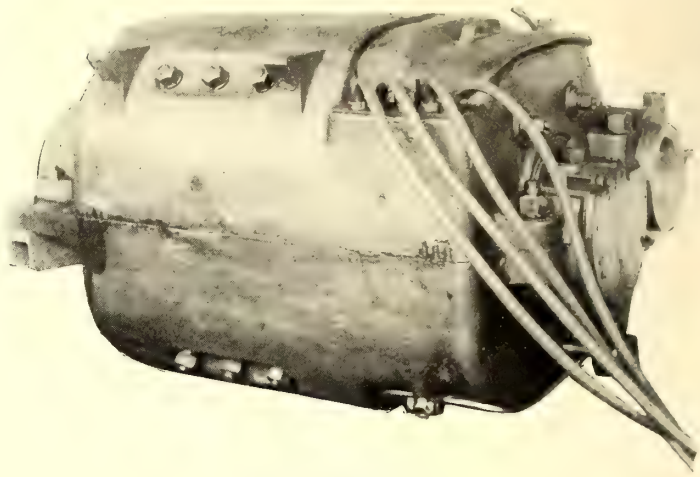
No. 68 and No. 69. The bearings are long and the lubrication is identical with that previously described. The commutator is built up of drawn copper segments, and is very deep, allowing for a great amount of wear. Bond wires retain the armature coils, and are sunk in the periphery of the core, thus obviating any danger of cutting them should the bearings be allowed to wear until the armature strikes the pole pieces. The amount of copper in the field winding is very large, and the motor is de-



ARMATURE OF NO. 50 C MOTOR

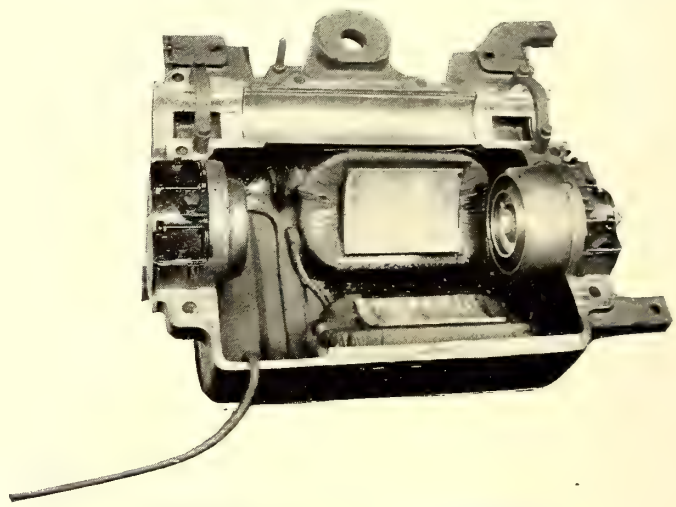
signed throughout with a wide margin for heavy overloads. The performance curve of the No. 56 motor is shown herewith.

The interior of the motor and armature can be inspected without dismounting the frame from the car axle. The method is to first run the motor over the pit, then unscrew the bottom half, which, with the gear casing, is hinged at the middle. The lower field can then be swung down, the armature being retained in either the upper or lower half at pleasure. As will be seen, the motor can be put in condition for inspection in this way without touching the suspensions, and in this particular is similar to the No. 49 or the No. 38-B.



The No. 70 motor is of still larger capacity, and was designed

CURVES OF NO. 56 MOTOR



for heavy, slow-speed interurban and elevated work over long lines. It will operate at 750 volts, which is an important point where the line drop is large. The motor is rated 110 h.p. to 115 h.p. at 500 volts and 150 h.p. at 750 volts. The poles are removable; the field winding is heavy; the armature is bar wound, absolutely oil proof and exceptionally well ventilated. The bearings are extra long and are carried in separate boxes and lubricated on both sides of their entire length.

The No. 50-C motor, which, rated at 150 h.p., is the largest of the company's standard types, and is designed for the heaviest railway work. In mechanical design it is similar to the No. 70. There is no provision for getting at the inside of the motor when on the car, as the motor is designed for use on trucks which can be run out from below the car when inspection is desired. When thus exposed, the bolts which hold the top field half to the lower half are unscrewed. As the lower half is supported on the truck,

NO. 50 C MOTOR

the upper half, with the upper half of the gear casing, can then be raised by a tackle. The armature can be retained in the upper half or left in the lower half, exposing all parts of the motor. The motor is lubricated in its armature and axle bearings by oil only. The armature bearing is a solid housing, provided with top and bottom bearing bushings. The object of this is to prevent the escape of oil. This bushing can be slipped off from the armature shaft on the commutator end, but to remove the bearing on the pinion end the pinion would first have to be taken off. The oil

LOWER FIELD OF NO. 50 C MOTOR

receptacle is packed with waste to prevent oil from spilling through the motion of the car. A wick embedded in this waste feeds both sides of the axle, making a continuous self-oiling bearing. If too much oil is poured into the receptacle the surplus is led outside through a tap into the street, so that there is no chance of the oil leaking inside of the motor. The top half of the field is furnished with two lugs for safety suspensions.

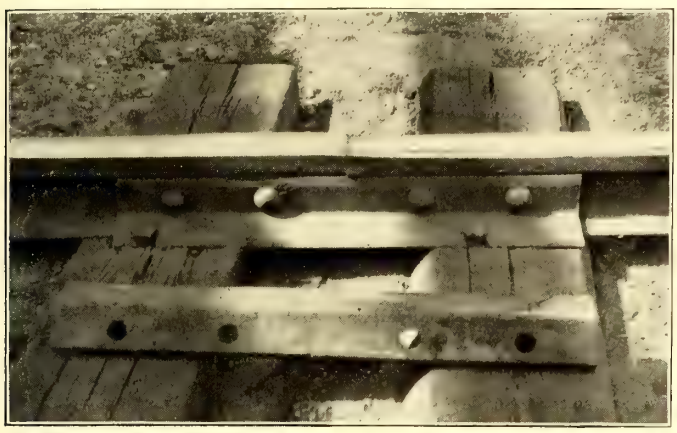
All motors are dust proof and shed water.

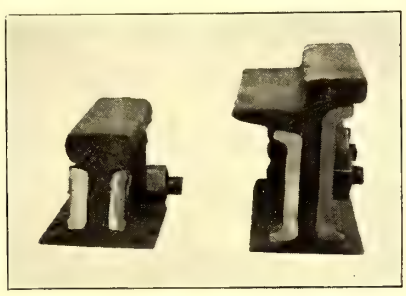
The Kansas City, Lawrence & Topeka Railway Company has been incorporated, with a capital stock of $2,000,000, to construct an electric railway from Kansas City, extending through Lawrence and the counties of Leavenworth, Douglas and Shawnee, to Topeka. The directors of the company are: John D. Bowersock, of Lawrence; C. C. Baker, of Topeka; John W. McDaniel, of Bonner Springs; John W. Hirst, of Omaha; W. C. Endsley, Henry G. Pert, George J. Hensinger, Walter A. Bunker, and W. E. Winner, of Kansas City, Mo. Mr. Winner's address is No. 711 Main Street.

Rail Joints

BY W. F. ELLIS, C. E.

It is an admitted fact that the weak point of railroad tracks is the joint, and, although the conditions on paved street railway





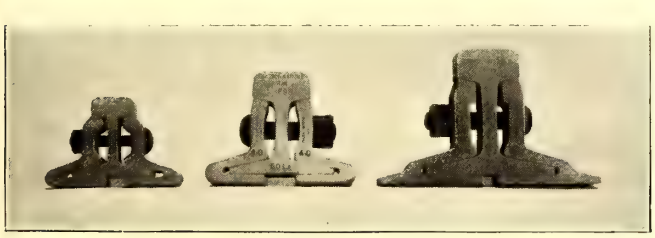


FIG. 1.—DEFECTIVE JOINT

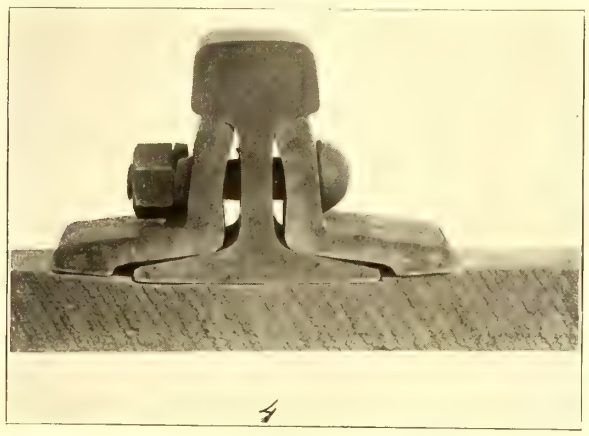
track are not the same as on steam railroads, yet on suburban and interurban roads, construction somewhat similar, though with a lighter T rail, can be employed.

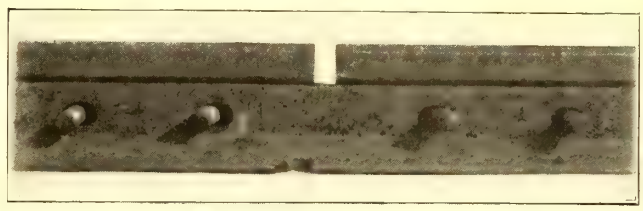
The joint fastenings on street railway track have been patterned somewhat after those in use on steam railroads, so that the failures on the latter will assist in finding a remedy for street railway joint troubles. When the old-fashioned chair joints were abandoned and "fish plates" (two straps of iron) were adopted, a change for the better as regards vertical strength, was secured, though all support of the base of the rails was sacrificed, being dependent on the bearing or support these straps gave at the point of contact under the head of the rail, assisted somewhat by a one-tie support at the rail ends. As creeping of track had to be prevented without slotting the base of the rails, suspended joints came into use with a flange to the "fish plates" at their base, extending beyond and level with the base of the rail, so as to allow a slot or hole in this foot, independent of the rail base. This gave the so-called "angle bar," which furnished greater vertical and lateral strength. Both of these types of joints are, of course, dependent for support upon frequent tamping of the joint ties. This, even on exposed track, is expensive, but for tracks on paved streets is practically impossible. As a result, the failure of

FIGS. 2 AND 3

such types of joints comes quickly, with loss to the rolling stock through pounding at the rail ends.

The reason for such failures is shown in Figs. 1, 2 and 3, where either the joint bars or rail ends at their contact, especially under the heads of the rails, give no support to carry the loaded wheel from one rail end to the succeeding one. Another frequent cause of failure of the angle bar type of joint is shown in Fig. 4, and arises where the tie is cut by the base of the rail, and not by the foot of the angle bars. This trouble can only be avoided by the most careful attention and inspection. An attempt to escape this trouble has been made on some steam railroads by making the foot of the angle bar ¼-in. above the top of the rail base, but this only aggravates the difficulty, as such joints have to carry a load





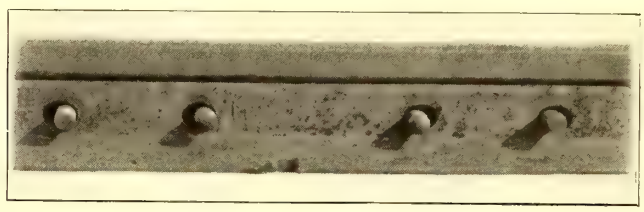


FIG. 4.—TIE CUT BY RAIL

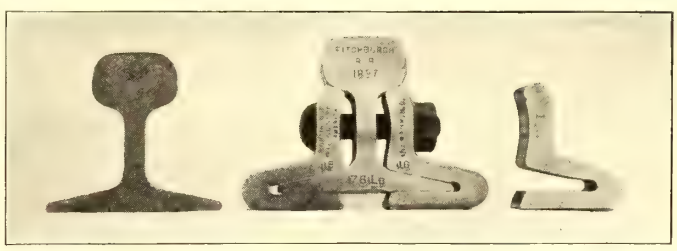
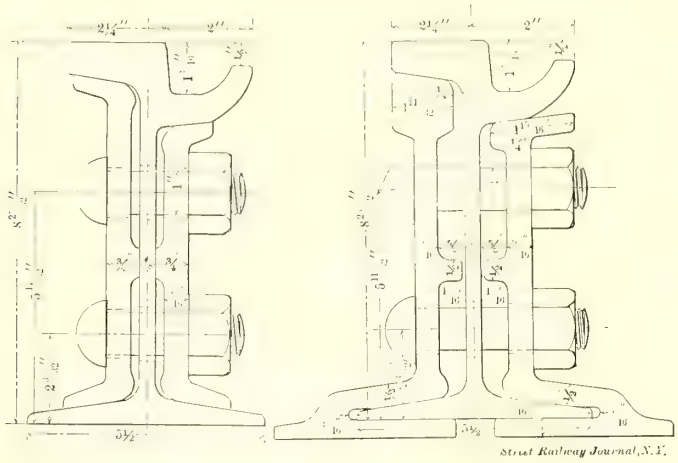
similar to a person with no support under his feet, but hung up by his ears.



Another cause for failure is where both joint bars have oval holes for cup head bolts, with round holes in the rail ¼ in. larger than the bolt shank, so as to allow an opening of ⅞ in., as shown at Figs. 5 and 6. One remedy to prevent such joints is to have

FIGS. 5 AND 6.—DEFECTIVE BOLT HOLES

right and left bars, the inside bar to have oval holes and the outside bar to have round holes, ⅛ in. diameter larger than thread of bolt; or a better remedy, where practicable, is to have alternate oval and round holes in each bar. In both cases the oval



FIGS. 7 AND 8.—TYPES OF CONTINUOUS JOINTS

holes in the bars should be punched to fit tightly the oval neck of the bolt used, when driven home by a hammer. Steam railroads use no larger diameter bolts than ⅞ in., but on girder rails 1-in. bolts are used to get greater thread area, yet with the greater care given to the application of joint fastenings on street railways, ⅞-in. soft steel bolts with raised rolled threads to 15/16 in. will have a greater tensile strength and elastic limit than even 1-in. iron bolts

with cut threads, and can be used to prevent the drilling of so large holes in the rail web. An example of such use is that the guard rail has been and is held properly in its position to the T rail of the tracks in the Boston subway by 7/8-in. diameter soft steel bolts having 15/16-in. cold pressed Harvey grip raised threads, where the lateral thrust on guard rails is very severe, owing to some 50 ft. radius curves in use.

As street railway track construction should be most permanent, especially at the joint, to relieve tearing up of the streets and loss from poor bonding, a joint which gives a continuous rail and supports the rail ends so as to insure the proper life of new rails and renovate old rails, should be exceedingly welcome.

The continuous rail joint, as made for T rails, is shown at Fig. 7, and gives this base support desired, being united to the fish plate or bar itself by being rolled, not formed, to fit any section of

FIGS. 9 AND 10

rail. The several types shown give such increased bearing surface with great vertical strength as to counteract the motion or play that leads to wear at points of contact so fatal to the life of joint fastenings. This joint has also been applied to what is termed the pear-shape head rail, Fig. 8. No angle bar type of joint could give any support to this rail, yet with the continuous joint base support, such rails have had additional life with better surface and alignment than could have been secured with any other joint.

The continuous rail joint has also been most successfully applied to deep girder rails. Owing to their height and unsymmetrical design a less length of joint can be used than with the ordinary center ribbed joint plate, and the non-appearance of the flat spot on the receiving end of double-track rails in well ballasted, paved streets, is absolutely insured. These two types of joints are clearly shown in Figs. 9 and 10.

British Manufacturer of Chilled Iron Wheels

The firm of Miller & Company, Ltd., was established in the year 1867, and shortly thereafter commenced the manufacture of chilled iron wheels. This firm is the pioneer of this industry in Great Britain, and claims the position of world pioneers in scientific methods as applied to iron founding.

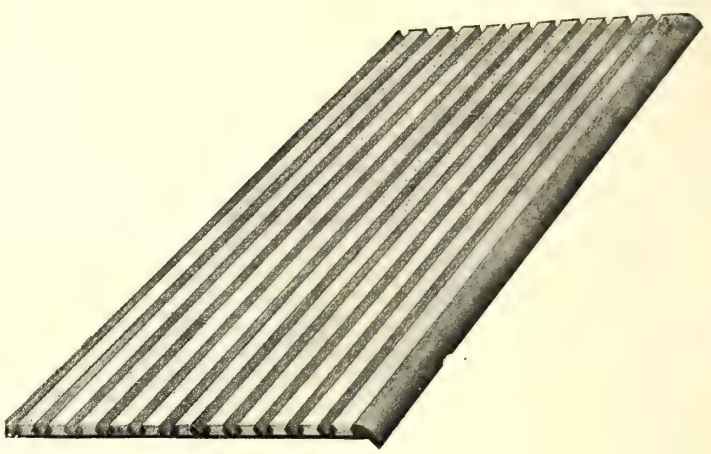
The chemical labratory has been the basis of the business, and success has been attained by unremitting attention to daily tests—chemical and physical—made by the company's chemists.

Messrs. Miller & Company's wheels are running on railways, tramways and in mines in Europe, Asia, Africa, Australia and South America, and the testimonials embodied in their recently issued catalogue bear ample testimony to the high quality of their products.

It seems that for many years before any other European or United States wheel makers gave heed to the chemistry of their manufactures—and were guided solely by rule of thumb—this Edinburgh firm was practising the methods and carrying out the experiments in daily practice which other founders, wheel makers and others, have subsequently adopted. The head office of Miller & Company is at Edinburgh, Scotland.

Non-Slipping Car Steps

Visitors to the street railway convention in Boston last year could not fail to observe the non-slipping steps in the various stations leading to the Subway and in very many of the finest business buildings of the city. Some will remember that the material which rendered these steps non-slipping was on exhibition at the convention, and recommended for use on street car steps, under the name of Mason Safety Tread. The patent is in



SECTION OF CAR STEP

the hands of an enterprising company having headquarters in Boston, and agencies in all the larger cities.

One year ago only a beginning had been made in the work with street railway companies. To-day over 1000 cars in various sections of the country are equipped with these treads, and duplicate orders have been given by nearly every road using them, the best possible evidence of satisfaction.

The merits claimed for this safety tread are its safety and dura-

CAR STEP

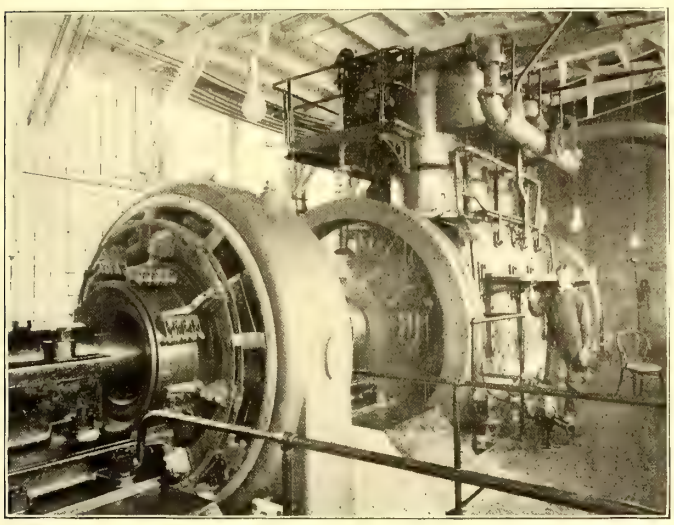
bility. It is durable because its base and ribs are of steel; safe, because there is always presented (even when the tread is half worn out) a surface of lead which holds the foot under all circumstances. Moisture, frost, light snow or grease does not affect this non-slipping quality. An open groove between every two lines of lead, as shown herewith, aids in holding the foot firmly, and catches dirt that would otherwise remain on the surface or be tracked into the car.

The safety tread will again be exhibited this year at Chicago. It is manufactured by the American Mason Safety Tread Company, of Boston.

New Carbon Works

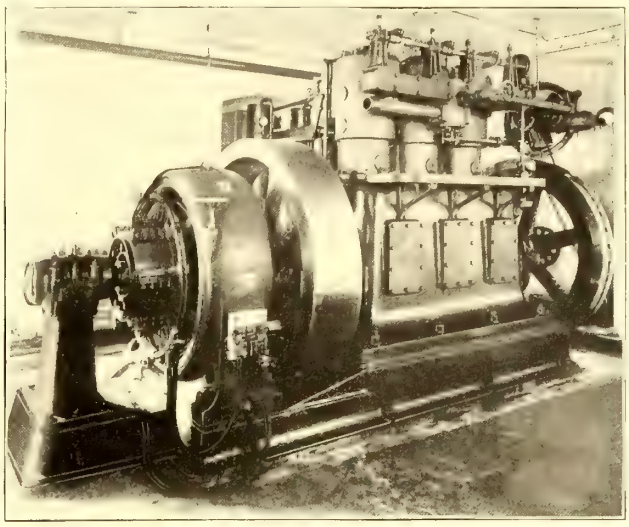
The Speer Carbon Company is the title of a new corporation recently organized to go extensively into the manufacture of carbon brushes of all styles and types, to fit all makes of motors and dynamos. The company will be entirely independent of any existing company or combination, as it is the belief of its organizers that the extent and importance of the electrical industry at present warrant the existence of more companies in this field than now exist. The president of the new company and acting manager is J. S. Speer, who, for a long time, was secretary and treasurer of the Partridge Carbon Company, and so is well acquainted with the requirements of the trade in this direction.

The location of the company's plant is at St. Mary's, Pa., on the line of the Philadelphia & Erie Railroad, and in the heart of the Pennsylvania coal and coke region, giving the best facilities for manufacturing carbon and for shipping. Here a modern factory has been erected, equipped with improved tools required in the business. An interesting feature of the manufacture is that all baking will be done by natural gas. Mr. Speer states that he will also make a specialty of the export trade.



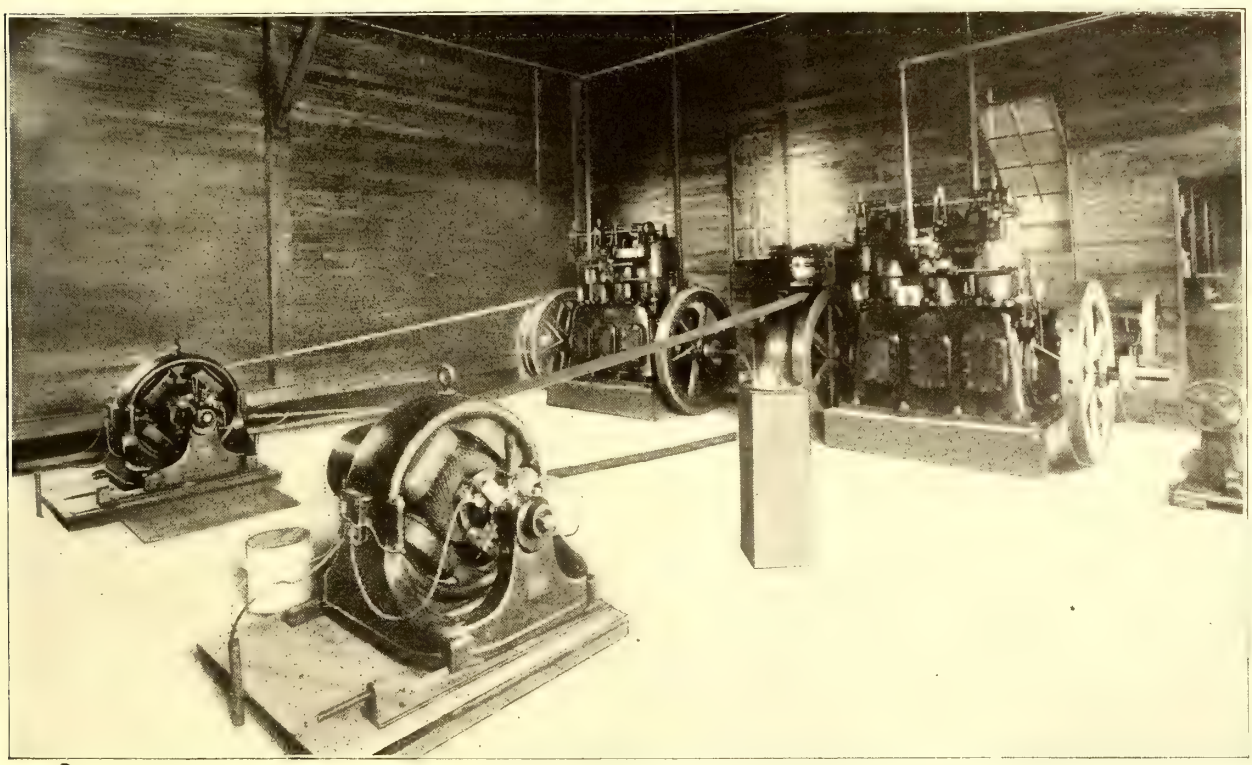
Gas Engines for Electric Railway Service

The gas engine, as a prime mover, has long promised an attractive solution of the problem of generating electricity economically, especially in small plants. The promise has, however, been slow of fulfillment, because this type of motor has been more or less handicapped by sundry imperfections seemingly inherent in its nature, which have greatly limited its utility in electric work generally, and practically excluded it from the railway field in particular.



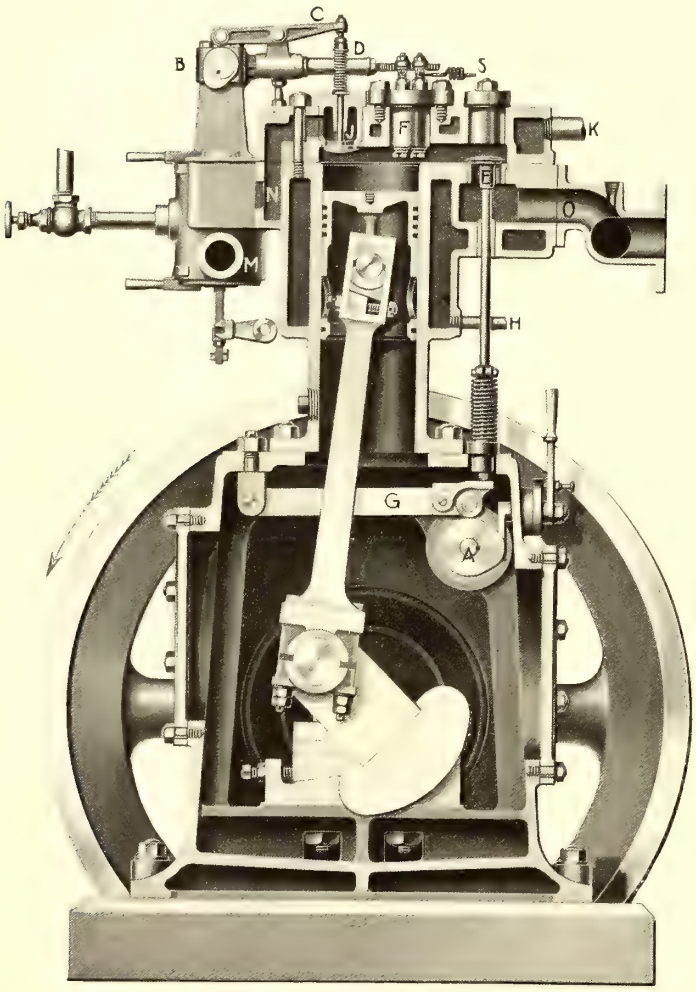
The recent announcement that the Westinghouse Machine Company, which, in a quiet, but none the less energetic way, has been carrying on a line of experimental work extending over a period of seven or eight years, has placed on the market a series of gas engines thoroughly tested, and which can be guaranteed in every particular, suited to the most exacting requirements of electric work, is therefore not without interest. It is stated that George Westinghouse has devoted much of his personal attention to this work, and that it was owing to his strong convictions of long standing as to the utility of the gas engine in various classes of railway power stations, and in other lines of electric work, that the Westinghouse Machine Company undertook with such successful results, the development of a suitable type.

In general appearance, the Westinghouse gas engines bear a marked resemblance to the Westinghouse steam engines. They are built in two-cylinder and three-cylinder patterns; the former in sizes from 10 h.p. to 70 h.p. inclusive, and the latter from 15 h.p. up to the largest powers desired. The largest engine yet built is of 650 h.p., and is illustrated in the accompanying engraving. It has been in regular and continuous use for over a year in part of the power plant of the Westinghouse Electric & Manufacturing Company, and its record there has shown in a marked degree the reliability and economy of this type of machine.



A section is given on page 718, through one cylinder of the three-cylinder engine, all three being exactly alike. This illustration and the description below will also apply with sufficient accuracy to the two cylinder engine. The engine is single acting, a feature which characterizes the Westinghouse steam engine, and which is absolutely necessary in a gas engine, for the reason that stuffing boxes and piston rods would deteriorate rapidly if exposed for half the time to an atmosphere of burning gases. The gas, which has first been mixed with the proper amount of air to fur-

650-H.P. GAS ENGINE AT PITTSBURGH

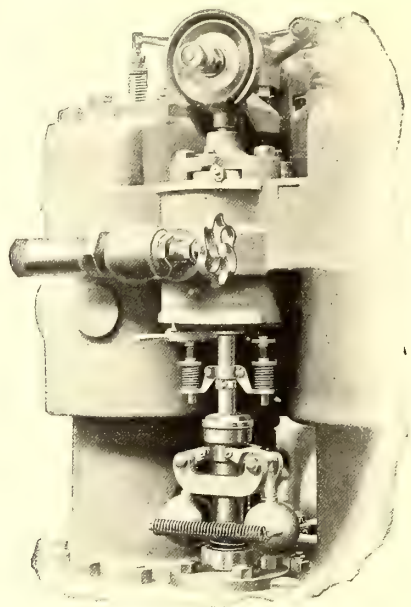


125-H.P. GAS ENGINE AT LONDON

RAILWAY POWER STATION AT HUNTINGTON, L. I., EQUIPPED WITH GAS ENGINES

nish oxygen for its rapid and complete combustion, is admitted through the opening *M*, passage *N* and valve *J*, into the cylinder. The engraving shows the piston near the top of its stroke and moving downward. Drawing in a cylinder full of mixed gas and air. On the return stroke the valve *J* closes, and this charge of gas and air is compressed into the clearance space between the top of the piston and the cylinder head. As soon as the piston commences its second downward stroke the charge is ignited by an electric spark. The igniter is shown at *F*, and will be described more fully later. The gas and air being thoroughly mixed in the right proportions, combustion takes place with a rapidity which may properly be called explosion, and the resulting heat raises the pressure to several hundred pounds per square inch. The gases under this pressure expand, driving the piston downward, and on the second return stroke they are expelled through the

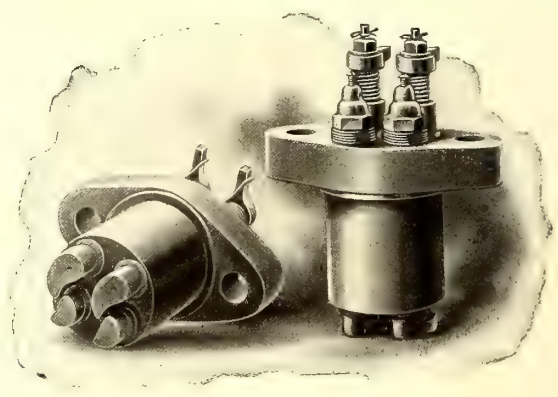
SECTION THROUGH CYLINDER



exhaust valve *E* and discharge *O*. When this stroke is completed all the parts of the engine are in position to repeat the same cycle of operations.

As will be seen, the valves and igniters perform their functions once for every two revolutions, instead of once for every revolution, as in a single acting steam engine; consequently the cams to operate these parts are mounted on shafts running only half as fast as the main shaft. Cams are used in preference to eccentrics on account of their more prompt action, and gears are employed for reducing the speed of the cam shafts.

The other main parts illustrated in the engraving are lettered as follows: *A* is the shaft which carries the exhaust valve cams, each working against a roller carried on the free end of the guide lever *G*. The admission valve is operated by the cam *B*, through the lever *C*. The guide *D* carries a plunger which actuates the igniter *F*. The cylinder heads and upper part of the cylinder are thoroughly water-jacketed, owing to the extreme heat to which these parts are subjected. The cooling water enters at *H* and is discharged at *K*.



The igniter, which is also illustrated, has two binding posts and two sets of current breakers; one set only used at one time, the other being held as a reserve and ready for immediate service. The current for the igniters is furnished by a battery and induction coil, and is connected with a three-point switch, so that the action of the current through the igniting apparatus may be reversed at will. In a direct current lighting or power station the main circuit may be tapped for supplying the igniters if desired.

The governor for both the two-cylinder and three-cylinder machines is shown herewith, and differs radically from those used on other makes of engines. In the latter the practice generally followed is to admit the same amount of gas and air, whatever the load, and to vary the number of explosions according to the requirements for power. Thus, with a single-cylinder engine running with a maximum load, the impulses may be as frequent as one for every two revolutions of the crank, while for a light load the impulses may be as infrequent as one to every ten or twelve revolutions of the crank. In the Westinghouse gas engine the impulses are given regularly, but the amount of gas and air admitted is varied according to the requirements of the load. The governor is of the two-ball type, and, as the balls move in and out with the changes of the load, the regulating valve moves up and down, increasing or decreasing the quantity of mixture admitted, without changing the ratio of the gas and air.

GOVERNOR

There are many other interesting details of this engine, which have been worked out with the care and ability characteristic of all the Westinghouse work, but which cannot be given here on account of lack of space. A short reference will be made instead to a typical electric railway plant at Huntington, Long Island, in which these engines are used.

IGNITER

The power house of the Huntington Street Railway contains two three-cylinder Westinghouse gas engines, with cylinders 9 ins. in diameter x 11-in. stroke, and rated at 50 h.p. each. Each engine is belted to a Westinghouse railway generator of 37.5 kw., 550 volts. The switchboard carries the usual generator and feeder panels, with also a panel for a storage battery, which is used as a balancer. This battery consists of 265 chloride accumulator elements, type E-7.

The road itself extends from Huntington station to Huntington Harbor, Long Island, a distance of over 3 miles, and has been in successful operation for about thirteen months. During the summer the travel is very heavy, and over 5000 passengers have been carried in a single day. The yearly car mileage is about 75,000. The cost of operation during this time has averaged about 13 cents per car mile. The gas is purchased from a local gas company.

The History of a Large German Manufacturing Company

The history of the Allgemeine Elektricitäts Gesellschaft, of Berlin, Germany, has been coincident with and illustrates most perfectly the development of commercial electrical engineering in Germany. The company has recently published in book form an extended account of the development of its business; this publication is intended to serve as a means of familiarizing its readers with the policy and methods of this large European concern, and shows in a comprehensive manner the tendency of the present time, namely, the independent motor transmission, instead of counter-shafting and belting, and the introduction of alternating current machinery over small areas and in isolated plants.

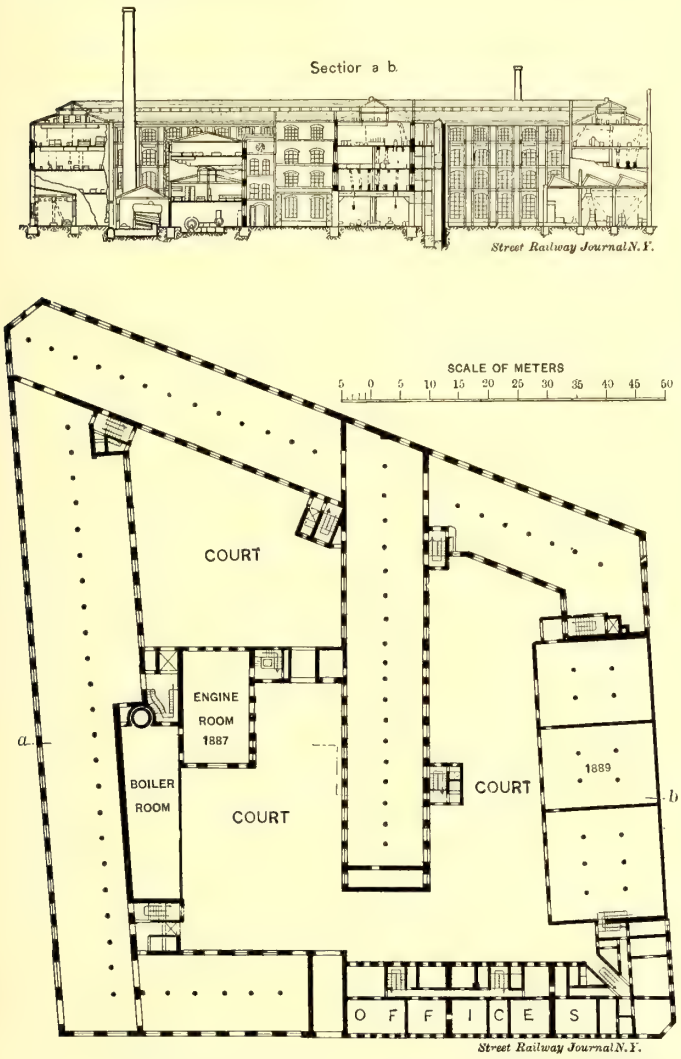


FIG. 1—PLAN AND SECTION OF WORKS OF THE ALLGEMEINE ELEKTRICITAETS GESELLSCHAFT

The company was started in 1882 by Emil Rathenau, the well-known engineer, and at present general director of the works, in order to acquire the European patent rights of Edison and to introduce incandescent lighting in Germany. After the signal success of the Munich exhibition, which was closely followed by the first illumination of a theater by electricity, the "German Edison Company for Applied Electricity" was formed, with a capital of 5,000,000 marks. This company brought into existence the first central station in Europe, which, with its various improvements, is to-day one of the most prominent and perfect on the European Continent. Entering into close business relations with the "Compagnie Contintale Edison," this original German company adopted in 1887 the name of the "Allgemeine Elektricitäts Gesellschaft," and has since grown until the balance sheet of July, 1898, showed a capital stock of 47,000,000 marks and a surplus of 18,000,000 marks.

It has been the policy of the company from the beginning to devote considerable attention to experimental work, which fact has enabled the company to continually remain in the front rank of the manufacturers of apparatus for applied electricity.

The company's works are located in Berlin, and a plan of its present works is given on this page. Of the buildings constituting these works the power station in particular should be noted, it being built separately and in the court, in exact conformity with the practice now followed in this country wherever space conditions are favorable. These works are kept running throughout the year day and night. The minimum power consumption between the hours of 3 A. M. and 6 A. M. is nearly 500 h.p., the maximum, between the hours 4 A. M. to 7 A. M. reaching nearly 2100 h.p.

The principal unit in the company's power station is a 1200-h.p. condensing engine, which is usually kept running, with its generator, from Monday 6 A. M. to Sunday 6 A. M. without stopping. The periods of larger consumption are taken care of by two 400-h.p. and several smaller high-speed direct connected generators. If it were not for the flexibility of the electric transmission system it would be impossible to run this large net of buildings from one station. The inconvenience of several smaller engine rooms and the expenditure connected therewith compared to this centralization of generating power presents a most excellent example of modern economical manufacturing methods.

In the earlier days, when the engineers of the A. E. G. realized the advantages of electric subdivision, they still adhered to counter-shafting in a way, inasmuch as they attached a motor near the ceiling of each section, and from there ran by belting and countershafting a row of milling machines, lathes, drills, etc. Although the expense of a number of individual motors is considerable, they recognized in time the desirability of still further subdivision in order to make their system as flexible as possible, and as well to permit the easy moval of machinery from one point to another. The advantages of decreased vibration, of clear head room, of cleanliness, entirely independent of any other considerations, marked a great era for the factory hands, and while these are items which perhaps cannot be expressed in dollars and cents, their advantages from the humane and ethic point of view cannot be questioned.

One great trouble in connection with the multiple introduction of small motors was the amount of attention that had to be paid to each, such as keeping commutators clean, but here, as in so many cases, necessity became the mother of invention, and the introduction of three-phase current and its distribution throughout the works obviated this difficulty most satisfactorily. The difficulties and many practical obstacles which barred rapid progress in this line of machinery were met with a will and determination for final success by the chief electrician of the A. E. G., Mr. v. Dolivo-Dobrowolsky, and in a way which not only made him

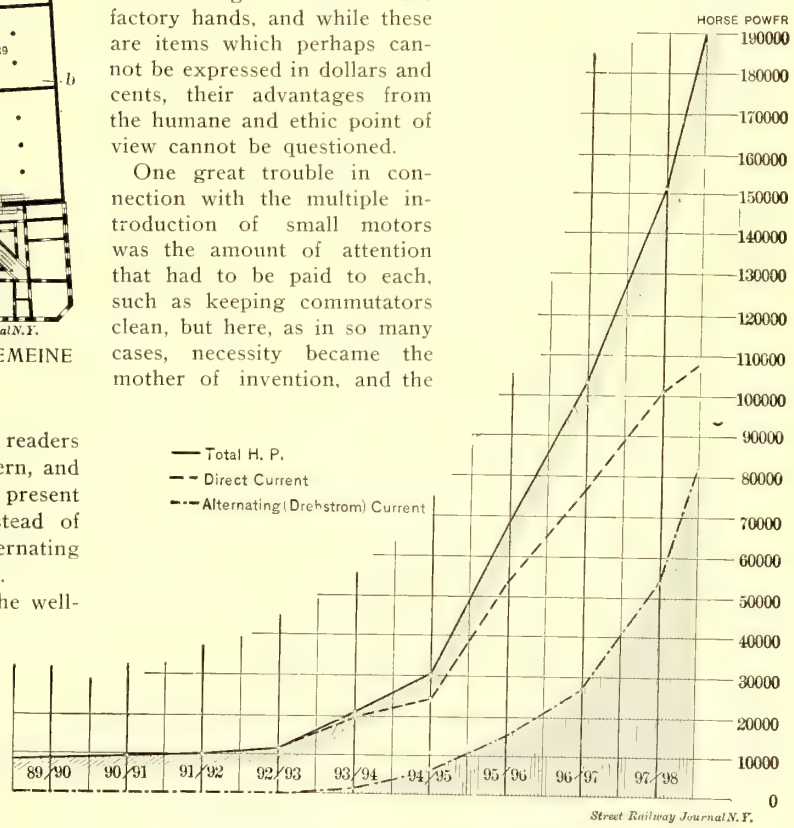

FIG. 2—OUTPUT OF DYNAMOS AND MOTORS FROM 1889-90 TO 1897-98

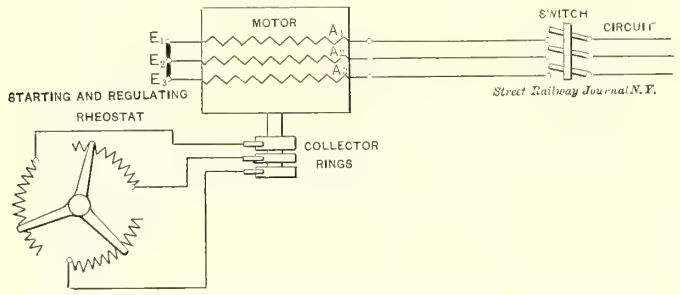
famous as an inventor, but assured him of the gratitude of all who, in improved apparatus, see a most concrete example of the progress of civilization.

The three-phase machinery, of which the A. E. G. was the pioneer, is rapidly coming into as general use as is direct-current machinery. This is clearly shown in the diagram Fig. 2, in which the amount of machinery in horse power, manufactured by the A. E. G. from 1889 to 1898 is diagramatically compared. While up to 1893 but 1000 h.p. of machinery was manufactured, and all of that of direct-current type only, the year 1897 to 1898 shows a



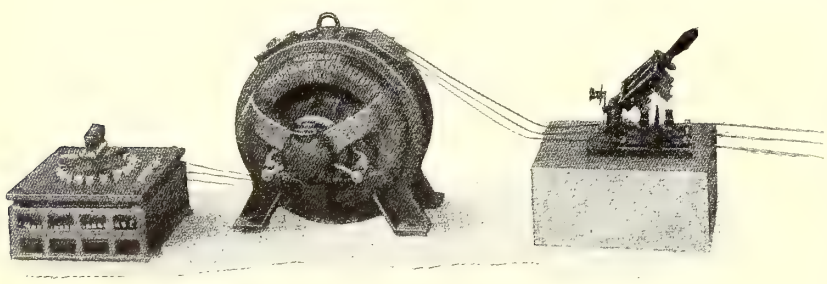


FIG. 3—METHOD OF STARTING MOTOR WITH ARMATURE RESISTANCE

total of 110,000 h.p. for direct current and 80,000 h.p. for three-phase machinery.

At present more than 12,000 people find steady employment in the company's works, and no expense has been saved in original investment to secure the most satisfactory results in practical manufacturing. The company has reaped rich rewards for its efforts.

An interesting and instructive insight into the kinds of motors of the three-phase type manufactured is given in this same book, in the form of a lecture delivered by O. Lasche, engineer of the company, before the German Engineering Society. He points out the difference between starting motors by short circuiting the armatures and by the introduction and gradual cutting out of resistance, the use and advantages of motors with collecting rings, etc.

The reduction of the phase differences is demonstrated in a very comprehensive manner to have a great bearing on the cost of running machinery and on the saving of copper conductors. Mr. Lasche explains that the phase difference between old and new type induction motors has been decreased by from 15 to 20 per cent. This will decrease the idle currents in the conductors, and,

THREE-PHASE MOTOR AND STARTING RHEOSTAT

allowing the same total actual and apparent drop, the conductors need be but 60 per cent in cross section, as compared with the old type induction motors. Four types of motors are built and used under different circumstances.

1. Motors with armatures short circuited for starting.
2. Motors with collector rings.
3. Motors with regulatable collector rings.
4. Motors with armature resistance. (Fig. 3.)

The first named is by far the simplest and is not subjected to any appreciable depreciation; it can run for weeks without attention.

The starting torque of these motors is double that of the running torque, and this makes them well adapted for lathe or milling work. In motors larger than 5 h.p. it is advisable to introduce a starting rheostat, in order to avoid heavy fluctuations, especially when incandescent lamps are fed from the same mains. It should be remembered that these starting resistances do not increase the starting torque, but simply react favorably on the main circuit and become, for reasons mentioned above, a matter of necessity when the current from central stations is used.

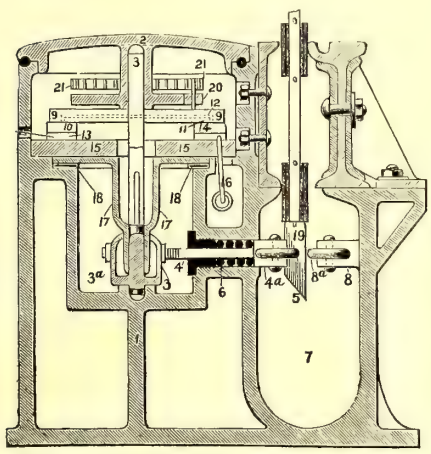
The introduction of resistances into the armature which necessitates the use of collector rings is more effective and economical; the starting torque can be regulated, and thus all reactions unfavorable to the supply mains can be avoided; the speed of the motors can also be properly controlled, which in many cases is desirable on account of the type of machine that may be driven. The starting with the two types of motors mentioned may be compared to the starting of a shaft by means of a toothed gear clutch vs. a friction clutch. The starting torque of a motor with armature resistance can be three times that of the running torque. Thus an ordinary armature with collecting rings can be used for starting purposes, and after the motor has acquired speed a simple device will short circuit the armature and release the brushes from the rings, thus giving this type of motor all the advantages of the first named kind, inasmuch as there are no sliding contacts whatever.

The third type of motor, that with a regulatable collecting ring armature, has no short circuiting device whatever. It is used wherever motors have to be frequently stopped and started and short circuiting devices on account of the time consumed would not be an economical arrangement. This motor finds its principal application in cases where different speeds are desirable, such as in crane work, lifts and printing presses.

The motor with armature resistance now remains to be discussed. In cases where the starting torque is not an important factor, but where the fluctuations on the mains ought to be kept at a minimum, and where, for this reason, the rapid speeding up of the motor is undesirable, this motor will be found to be best adapted for the service. Its fundamental principle is similar to that of the collecting ring armature, inasmuch as the armature offers considerable resistance in starting. The difference between these two types is the location of the resistance; in the one case the resistances are outside, and in the latter case they are built into the armature and cannot be regulated. The armature contains two sets of coils; one short circuited within itself and of high resistance, and the other of smaller resistance and closed by means of a short circuiting device. In starting, the latter is open, and the motor with the high resistance armature starts slowly. When it has reached half speed the second coil is closed, and the motor, reaching its full speed, acts like the short circuited armature motor. The cooling surfaces not being as great as in the other cases, the motor cannot stand excessive overloads, but on account of its simplicity and cheapness it finds considerable application.

The transportable and flexible shaft drill and milling machines form another important section of the A. E. G.'s output, and these machines should find considerable application in mines and such places, where the absence of brushes and consequent absence of sparking, form a valuable feature.

As a whole, this brochure furnishes to the buyer, as well as to the engineer, valuable data; to the latter it gives lucid explanations; to the former it shows in a convincing manner the attention and engineering skill devoted to the manufacture of electrical machinery.



The company has recently published a pamphlet descriptive of its electric railway business, which gives a full list of the electric railways built by it or in the course of construction, brought up to May, 1899. This list comprises roads having a total of 1283 km. of track, 2268 motor cars and twenty electrically driven snow-plows. They include roads in many countries outside of Germany; among them, Spain, Chile, the Argentine Republic, Italy, Russia, and Austria. The pamphlet also contains a large number of very attractive half-tone engravings of many of these different lines, with explanatory notes in German, French and English.

The Carrollton Electric Railway Company, of Carrollton, Ky., has been incorporated, with a capital stock of $20,000, to construct an electric railway at Carrollton. The principal stockholders of the company are: James M. Grant, J. F. Jett, M. I. Barker and M. L. Downs, of Carrollton.

New Type of Conduit and Surface Contact System

The engraving below shows a section of a combined contact and surface contact system, which has recently been patented by Messrs. Stendebach & Linker, whose interests in Great Britain and the United States are represented by Estler Bros., 27 Ledenhall Street, London. The use of the open conduit is only to admit a contact closing device; it can therefore be made much smaller and shallower than where live contacts are carried in it. If desired, however, the ordinary section of conduit can be used. In this case the device illustrated is useful for keeping the contact sections dead, except during the passage of the car.

The construction of the later form of conduit is as follows: The cast iron box, in which is carried the mechanism, is partly rectangular and partly cylindrical. The cylindrical part of the box is fitted with a cover, 2, flush with the surface of the street. Inside this cylindrical portion, a bar, 3, is arranged, consisting of two parts, the bottom of the lower portion forming a pan-like flange. The lower end of the bar, 3, rests in a socket of a web of the box, 1, while the upper end fits in a socket of the cover, 2. The pan-like part of the bar, 3, is fitted with a toothed wheel, 3a, engaged in a rack, 4. The end of this rack, 4, which projects into the conduit, 7, has a widened head, 4a, with a roller, 5, and this is pressed outward by the spring, 6. Opposite to the roller, 5, in the conduit, a bracket, 8, carries a second roller, 8a. The bar, 3, is fitted on its upper end with a disc, 9, of insulating material to which the contacts, 10 and 11, are fixed and connected together by a wire, 12, embedded in the disc, 9. The bar, 3, is encased by the small cylinder, 17, which is screwed on to the box, 1, and the lower part of which rests in the pan-like part of the bar, 3, and this is filled with mercury to exclude moisture from the space containing the contacts, while the upper end of the cylinder, 17, is made air-tight by means of the India-rubber ring, 18.

SECTION OF CONDUIT

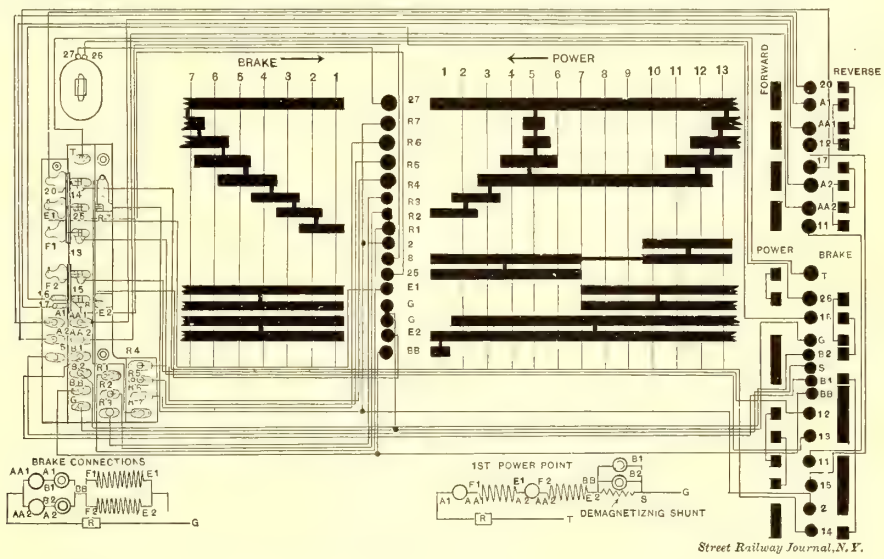


DIAGRAM OF ELECTRIC BRAKE CONTROLLER

If the contact closer fitted to the car now passes through the conduit between the rollers, 5 and 8a, the rack, 4, is forced into the box, 1, and this imparts a circular motion to the bar, 3, which in turn causes the disc, 9, to revolve, bringing the contacts, 10 and 11, and the counter contacts, 13 and 14, respectively, together. The contact, 14, is joined to the feeder cable, 16, while from 13 the current is led to the contact studs in the center of the track from which the current is taken up by the motor car in the manner described above. As soon as the contact closer passes the roller, 5, this is set free, and the rack, 4, is pressed back to its original position by means of the spring, 6, which is reinforced by the spiral spring, 21, fitted in the cover, 2, on a pin, 20, of the disc, 9. Instead of the springs counterweights could be used.

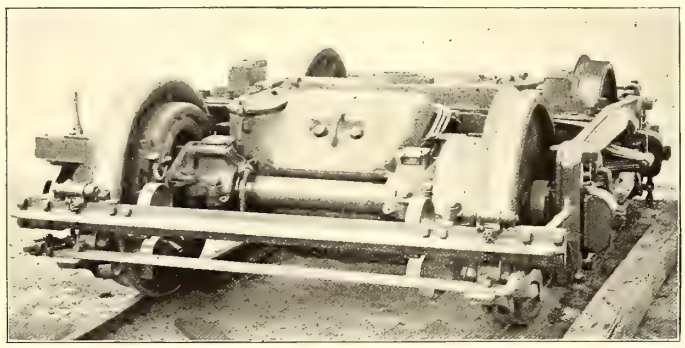
Improvements in Electric Brakes

The General Electric Company has made certain changes recently in the arrangement of the motor and brake circuits of its electric brake which modify to a considerable extent its method of operation. This brake, it is well known, consists of a cast iron disc keyed to the car axle, and a circular electro-magnetic shoe, which forces the disc and is held so that it cannot revolve. Both disc and shoe are split diametrically for convenience in installing.

When the brake is installed on the same axle with the motor, the brake shoe is supported and kept from revolving by horns projecting from a special motor axle cap. When the brake is mounted on a free axle, i. e., an axle without a motor, the shoe is fitted with a standard axle bearing sleeve and kept from revolving by a bar connecting it to the truck frame. In the case of double-truck cars, two brakes are installed, one on each axle of a truck without motors. Under these conditions a bar will connect the two brake shoes.

The controller for operating the brake is similar in appearance to the well-known "K" type of series parallel controller. The controller handle, however, is not blocked at the "off" position, but may be moved beyond it to a series of notches operating the brake.

The changes in connections referred to have been introduced with the view of decreasing the liability of producing flat wheels, and consists principally in connecting each brake shoe directly in series with the armature of the motor on the same axle. These connections are shown in the lower left hand corner of the diagram herewith, which is the development of the company's latest two-motor electric brake controller.



With such an arrangement it is practically impossible for the wheels to slide for a distance of more than 2 ft. to 3 ft., as the brakes automatically release when the wheels start to slide. The theory of this is that if either axle ceases to revolve, the motor armature in series with the brake shoe ceases to generate current, thereby releasing the brake. In addition, however, there is an actual demagnetization of the shoe by the current from the other armature, which tends to flow in the reverse direction through the armature of the first motor, and the brake shoe in series with it. It is claimed, therefore, that a much greater braking effect can be applied without danger of skidding the wheels than with any other form of power brake, an advantage which is readily appreciated in making emergency stops.

The method of demagnetizing the brake shoes has also been changed, and, instead of passing the current from the trolley through the shoes on the first power point, a portion of the main current passing through the motors is shunted through the shoes. The connections for demagnetizing are shown in the small diagram in the lower right hand corner of the diagram mentioned.

The construction of controllers has also been much improved, and the latest two-motor controller (B-13) contains many desirable features lacking in the earlier type. The combinations of motor and brake circuits for power and braking are effected by means of an auxiliary cylinder located on the right-hand side of the controller. This cylinder is thrown in either direction by means of a cam on the main cylinder and a suitable lever. The main cylinder serves to series parallel the motors on the power side, and to regulate the resistance both for power and braking.

As the usual interlocking mechanism between cylinders is used, all arcing takes place on the main cylinder, where an efficient magnetic blow-out provides for its prompt and complete extinguishment.

Electric brake shoes have been designed for use with the various types of standard motors, and adapted either for mounting upon the motor or directly upon the axle. Where the motor

TRUCK EQUIPPED WITH ELECTRIC BRAKE

and brake are mounted on the same axle the shoe is held by a support which in some cases is combined with the axle cap, and in others is merely a steel yoke bolted to the motor frame. The axle suspended type of brake shoe is only used where double-truck cars are equipped with but two motors, and on trail cars. They are provided with brass axle linings and grease cups, and are held from revolving by a bar which passes through the horns on the shoe, and is bolted to the truck frame. Engravings of

CAR AT CLEVELAND EQUIPPED WITH ELECTRIC BRAKE

these shoes were published in Street Railway Journal for March, 1899.

All brake shoes are fitted with wearing plates, which are bolted to the shoe casting, and which can be readily renewed at slight expense when they become worn out.

The use of electric brakes on train cars is attended with exceptionally good results, as it is possible to obtain an exceedingly smooth and simultaneous braking of two cars, doing away with the bumping and jerking of the trail car, which are so objectionable.

The Ashland & Catlettsburg Street Railway Company reports a season of unusual prosperity. During July 86,000 passengers were carried without accident or injury. Most of this business was obtained by the attractions which were furnished free to patrons of the road at Clyffside Park. These beautiful grounds, which are second to none in this country, were visited by 818 picnic parties during the season, and more are booked. The park contains a beautiful lake, covering 7½ acres, numerous boat houses and boats, a dancing pavillion, ladies' cottage, Dutch oven, coffee house, arbors, swings, orchestra stand, telephone booth, refreshment stands, croquet grounds, Indian mounds and a natural theater. The company intends building a large theater next season.

An Important Chicago Engineering and Contracting Company

The Arnold Electric Power Station Company has exercised an important influence upon power station design in Chicago, through its work in connection with several stations, principally in the suburbs. One of the most recent of these is the Chicago & Milwaukee Electric Railway, a 27-mile line, extending along the lake shore north of Evanston. Its equipment, which includes the use of rotary converters and three storage battery auxiliaries, represents several steps in advance of ordinary high-speed interurban railway practice. These transformers and converters receive their energy over a three-phase transmission line extending back to the high-tension alternating current generators in the main power house. This power house also contains direct current machinery sufficient to supply the section of road adjacent to it. The construction of this entire line, with the exception of the first section and the rolling stock and track, has been carried out by the Arnold Company. This contract included the engine, direct current and alternating current generators, switchboards, transformers, rotary converters, economizer, pumps, mechanical draft, condensers, piping, cooling table and reservoir, power house building, battery room, car houses, offices, two sub-stations, overhead equipment and transmission line erected complete, ready for operation. It should also be stated that the original plans were drawn up by Mr. Arnold, and in his contract work he guaranteed a certain specified efficiency for the entire plant. This policy of working out its own solution of an engineering problem, of submitting plans and specifications with its proposition, together with an economy guarantee covering the entire installation, takes this company at once out of the ordinary class of contracting companies and places it in a position peculiar to itself. Another unique feature of the Arnold Company's methods is that it is in no way connected with any manufacturing company, which leaves it free to purchase machinery and apparatus of any make upon the open market.

The Arnold Electric Power Station Company was organized in 1896 to make and sell the parts peculiar to the "Arnold system" of power station construction, and acting in this capacity it has supplied a number of plants with magnetic clutches, shafts, quills, box stands and couplings. Among these plants may be mentioned the Fort Dodge Light & Power Company, Fort Dodge, Iowa; Chicago Board of Trade; Englewood & Chicago Electric Railway; Land Title & Trust Building, Philadelphia; University of Michigan, Ann Arbor, and W. B. Conkey Company, Hammond, Ind. Through natural development this company has gradually broadened the scope of its work until it is now in position to make a proposition for furnishing and erecting in place entire electrical properties, and it already has an enviable record along this line. Among its recent completed contracts are the entire power plant and building of the Imperial Electric Light, Heat & Power Company. This plant is a large central station using 500-volt generators working in parallel with a storage battery auxiliary. By dividing this battery into two parts a distribution system was devised which allowed the use of 220-volt incandescent lamps, arc lamps and power motors off the same mains,—a decided departure from central station practice. This system has been adopted for another large central station since the erection of the Imperial plant.

The Arnold Company was also given the contract for the complete light, heat and power plant erected in connection with the new railroad shops of the Chicago & Great Western Railroad at Oelwein, Iowa. This contract comprised not only the heating and lighting of the shop buildings, covering many acres, from a central plant, but also the application of a large number of motors for various uses. This has been the first plant to adopt the Arnold magnetic clutch for line shaft work, though these clutches have been used for some time in connection with the three-way couplings, which are a part of the company's system of power station construction. Another notable installation recently completed is the isolated plant for the Garrett Building, Chicago.

The Citizens' Traction Company, of Oil City, has been granted a franchise for the construction of an electric railway within the city limits. D. T. Borland, D. J. Geary, Joseph Manning, F. W. Bowen and others are interested in the new company.

Air Brakes

The advantages of the use of power brakes for every class of rapid transit service are now so generally recognized that few, if any, railroad men question them. In fact, the problem at present is not so much, should a power brake be employed, but which power brake should be used. The same condition faced the steam railroads thirty or forty years ago, but, after many experiments, air was finally selected as the most efficient and desirable power to use for braking purposes. It is hardly necessary to discuss here the advantages of compressed air for this service, and the attention of the reader will be directed instead to some of the most recent apparatus for braking street railway cars, manufactured by the Standard Air Brake Company, the first company to engage in the business.

The Standard Air Brake Company, which proudly claims the title of the "pioneers," makes several types of compressors for different classes of service. One of these is the geared axle-driven compressor for the use of high and slow speed electric cars. Some particulars of this compressor are published in the STREET RAILWAY JOURNAL for June, 1898, but the latest type of compressor, in which certain improvements have been made, is shown in Fig. 1. A split spur gear, keyed to the car axle, drives a second gear, which is mounted free on the pump shaft. This gear is connected to the driving shaft of the duplex compressor by means of an ingenious friction clutch, which is thrown into operation when the pressure in the reservoir falls below a fixed minimum, and is thrown out of connection when the pressure rises to the predetermined maximum limit. Moreover, when, after an application, the air in the brake cylinder is released, the clutch is automatically thrown in, although the reservoir pressure may have been reduced but a pound or two, giving maximum pressure for all stops. By an ingenious arrangement the engagement of clutch members takes place only when the speed of the car is reduced and the pressure removed from pump cylinders. The company also builds the same type of compressor without the clutch attachment. Its structure, however, is much heavier than that of the "clutch" machine, as it is generally used where the service is exceedingly hard on the car mechanism.

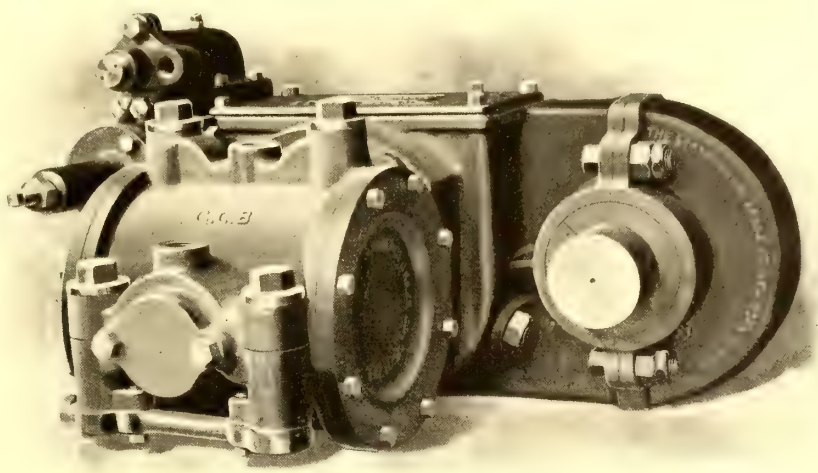


FIG. 1—AXLE-DRIVEN GEARED COMPRESSOR

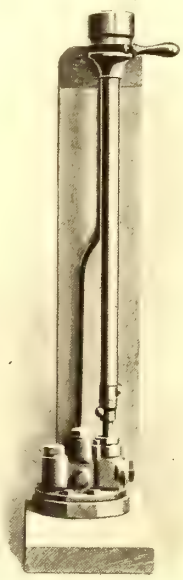

FIG. 2—OPERATING HANDLE

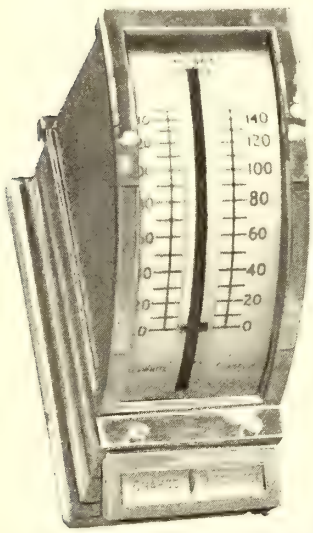
An idea of the compactness of the machine can be derived from the statement that only 7 ins. of actual space between the motor and the hub of the wheel are required for mounting this compressor. All parts are dust proof, and operate in a bath of oil. There are no stuffing boxes used, and the piping is reduced to a minimum. There is an instantaneous application of the brake, and quick release. The parts are few, and there are no bolts inside the compressor casing. The power per car mile of operating the compressor, it is said, does not exceed ⅛ h.p.

For trains and heavy electric service the company builds a motor compressor. Full particulars of its motor-driven braking system were published in the STREET RAILWAY JOURNAL for April, in which number an extended description, with illustrations, was also given of the company's automatic current controller, which is one of the most ingenious and efficient devices for the use for which it is intended ever constructed. No reference, however, was made at that time to the operating valve employed. This device is a valuable portion of the system, and is illustrated in Fig. 2. The Standard Air Brake Company has long followed the practice of combining the pressure gage with the operating head, and, by means of a staff, transmitting the movements of the handle to the valve, which may then be placed down out of the way, either on the platform or underneath the car. It will be noted that the gage is where it must constantly be seen, and, being covered with very thick plate glass, cannot be damaged unless deliberate force is exerted. The handle operates in the slot shown under the gage, and when withdrawn, the staff is locked in its position, so the brakes cannot be tampered with when the motorman is at the other end of the car. The head is of polished bronze, which, with the black tubular casing of the staff, presents a very neat appearance—a point much appreciated by managers who take pride in the appearance of their cars.



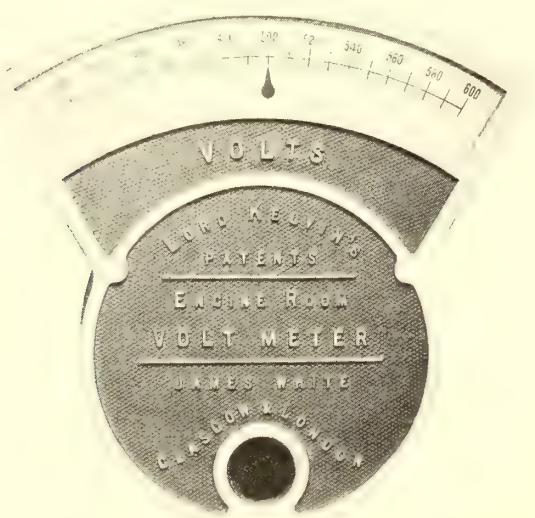
The company makes three types of operating valves that are manipulated by this operating staff. The O V M valve shown in the cut, and the O V N, have slide valves which will remain tight; they are provided with ports for service and emergency applications, and the manipulation is so simple that it can be learned by any motorman in a few minutes. The O V M, which is located on the platform, is used with motor compressor equipments, while O V N, of which there is but one per car, is used with the geared axle compressors. It is located under the car directly on the brake cylinder head, unless trailers are used, when it is placed on the train pipe line and a special bracket supplied for its support. The use of the single valve on the brake cylinder admits of an instantaneous application of the brakes, a much quicker release, and is very economical of air. The motion of the handle is transmitted through a pulley on the end of the staff below the platform, and a single line of chain and rod from either end of the car, to a bell crank lever, which in turn pushes the valve stem in and opens the valve.

The company's shops in Jersey City present a most busy appearance. They measure 100 ft. x 200 ft., and so many orders have been received for air brakes as to require their operation for twenty-four hours a day during the past summer. The present facilities of the shops are ten equipments a day, but if necessary the company could turn out fifteen equipments a day. One hundred men are employed, and the machinery equipment is of the latest and most complete type. The company makes a specialty of testing all equipments before shipping, and has a special department where these tests are carried on. This activity would indicate that street railway companies are taking a great interest in the air brake question. The company has some very large orders on hand, and in several instances has been obliged to refuse orders from roads which put off the placing of contracts until the last minute and then demanded early deliveries.

The Railway Construction Bureau of Japan, it is said, has at last decided upon a plan for an elevated railway between Shinsenza and the central railway station, to be built at Eirakucho. The work is to begin within one year, and $1,800,000 is to be appropriated for buying the necessary land. The requirements of this work will be very large. Further particulars can be obtained by addressing the Minister of Public Works, at Tokio.

Electrical Measuring Instruments

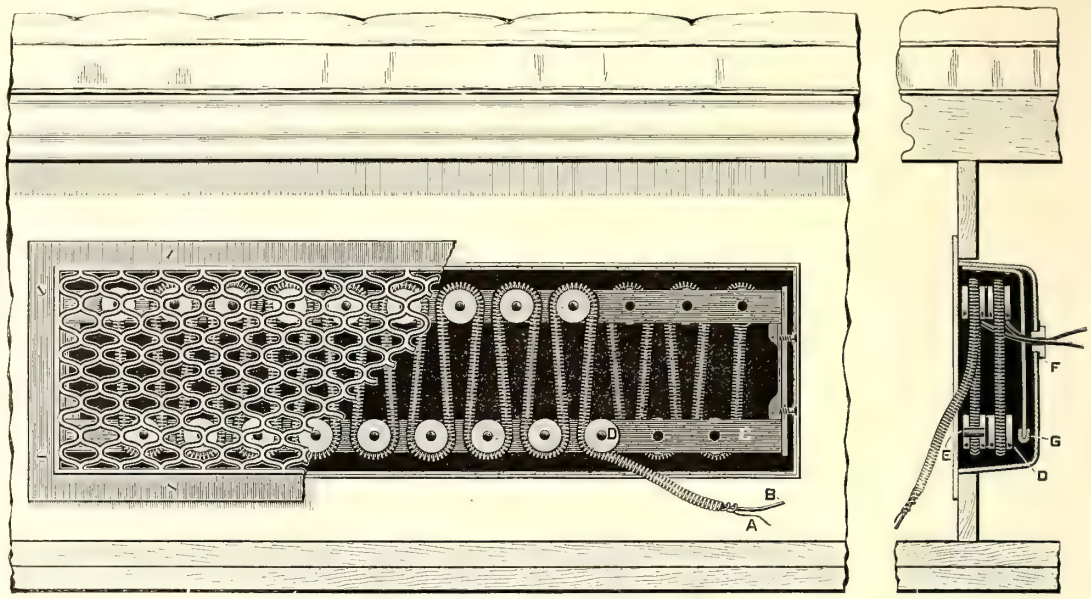
The accompanying engravings show two of a series of electrical measuring instruments manufactured by James White, of Glasgow, under patents granted to Lord Kelvin. Mr. White makes a specialty of all kinds of electrical measuring instruments, including ammeters for direct, alternating or multiphase circuits, of the dial or edgewise type, with 5-in., 7½-in. or 10-in. scales. These



5-IN. SCALE KELVIN EDGEWISE OVERTYPE AMMETER

appliances have no temperature error, and are made in sizes to measure up to 1000 amps. He also manufactures the Kelvin direct reading wattmeters for direct, single-phase or multiphase systems, and the Kelvin millicellular electro-static voltmeter. The instruments illustrated are respectively a 5-in. scale edgewise overtype amperemeter, and a 12-in. scale, moving coil, voltmeter.

Improved Type of Car Heater



The latest and improved type of American Electric Corporation panel heater, which is manufactured and sold by the Simplex Electrical Company, of Boston, is illustrated herewith. The view exposes the details of construction, which are as follows:

12-IN. SCALE KELVIN MOVING COIL VOLT METER

The case is the conventional one of cast iron, bronze finish, as are all the cases of the different types of heaters. The electric heater consists, as shown, of two coils of special non-corrosive wire that is not affected by high temperature, moisture or acid fumes, and consequently, is practically indestructible. These coils have a stout asbestos cord *(B)* running through their center from end to end. The oblong steel frame *(C)*, provided with suitable pins projecting from either side, furnishes supports for the round grooved porcelain insulators *(D)* on which the coils are mounted. The asbestos cords are drawn taut and fasten on their respective sides to the terminal porcelains at either end, to which also the coils are made fast independently of each other.

The asbestos cord furnishes a continuous support throughout

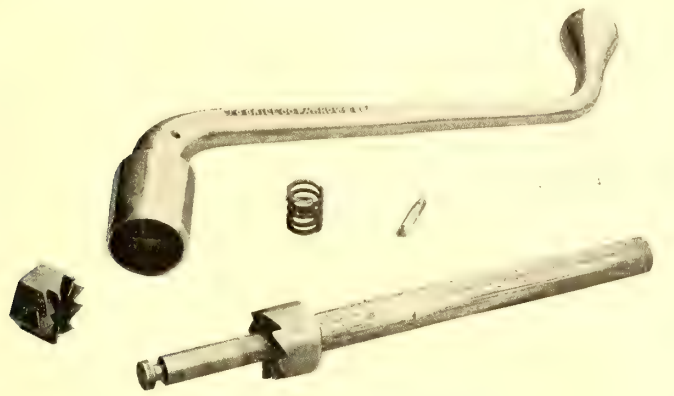
NEW ELECTRIC CAR HEATER

the length of the coils, preventing the possibility of a coil getting out of place, and maintaining it in place without tension on the coil.

Connected to the coils by good mechanical joints and soldered, are rubber covered, flexible, terminal conductors, which pass through porcelain bushed holes *(F)* on the outside of the case. This form of heater is used in all the different types of the coil spring car heaters, of which the company makes eight different sizes and styles. As indicated in the engraving, this heater is of great simplicity in construction and it is claimed by the makers that any part, except the case, can be replaced from the stock room or repair shop of any electric railway company.

The company also makes the panel type heater, the popular form for side seat cars having paneled risers underneath the seat. The American electric heater for cross seat cars, it is claimed, takes up less space underneath the seat than any other. It is only 2 ins. thick, while giving a maximum possible distribution, as these heaters are made in several different sizes so as to fill the entire length of the space between the seat uprights of the different manufacturers of car seats. One special point made in favor of this heater is that passengers cannot injure it by bracing their feet against it, or produce short circuits, or scrape mud and slush into the heater on to the coils when using it as a foot warmer.

The company also makes many other types of heaters, among others a new type known as the "enameled heater," in which the heating coils are embedded in enamel resistance on cast iron plates. These heaters are light, strong and entirely insulated, and while useful in any cross seat or side seat without risers, are particularly adapted to elevated cars.



The Simplex Electrical Company also does a large business in American switches, and in the D. & W. fusible cut-outs, which it furnishes with all equipments, and claims to have been the first to introduce the non-explosive fusible cut-out.

It will be of interest to know that the American heaters were selected for use in all the first-class staterooms of the new White Star Line steamer, "Oceanic," and that these heaters were not bought until after a competitive test had been had with other heaters. Many other electric heating devices are used on this and other transatlantic steamers manufactured by this company, but this is the first ocean greyhound (as well as the biggest) to have her staterooms heated electrically.

The company has recently published a catalogue giving full information about its different heaters.

Ratchet Brake Handle

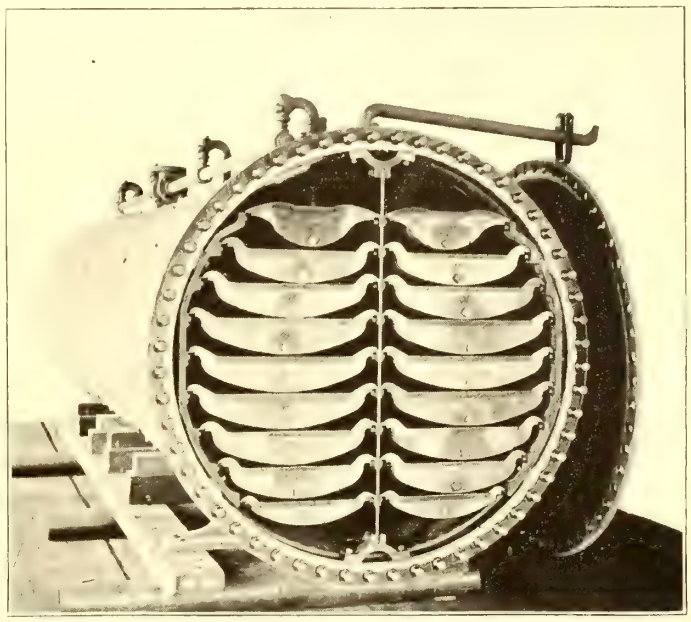
The Brill ratchet brake handle is one of those small but complete details of car building which form, however, a most important part of a car equipment. Besides the handle itself and the brake staff it is composed of but four pieces, and of these only two move. To the unobservant eye it presents no difference from the old-fashioned fixed handle. At the base, however, it is slightly enlarged to accommodate a hexagon ratchet, and beneath this ratchet a

PARTS OF RATCHET HANDLE

fixed round ratchet upon the brake shaft. These are shown in the accompanying engraving. The upper ratchet is held down by the spring. To prevent the handle coming off a groove is cut in the top of the brake staff and the pin is screwed into the handle at a point where it engages the groove in the brake staff and prevents the handle from being removed. The hexagon nut rises and is forced down by the spring when the handle is reversed in a hexagon chamber in the handle.

Feed-Water Purifiers and Heaters

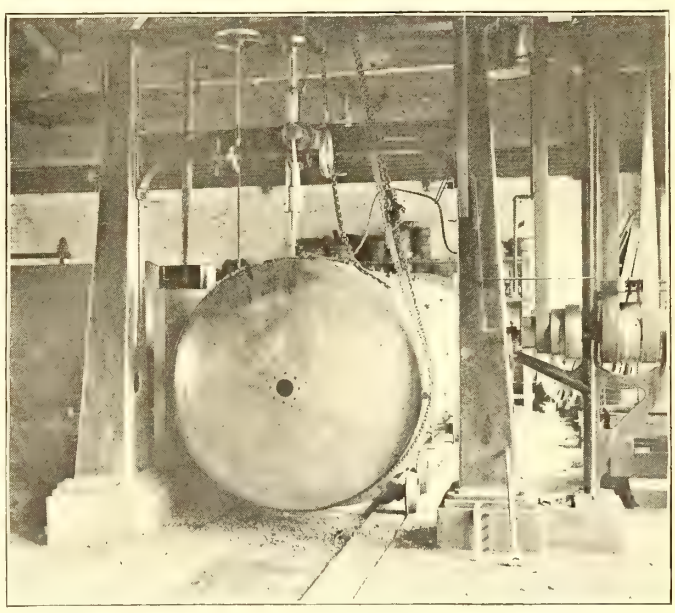
Among the auxiliary appliances of a steam power station located in a district where solids are held in solution in large quantities in the available feed-water supply, none is more important to the economical operation of the boilers than purifiers or combined purifiers and heaters. These devices anticipate the heat effects that would naturally take place in the boilers, by bringing about the action in a receptacle that is easily cleaned, and so deliver comparatively pure water to the boilers. As the principles on which these appliances operate are found in nature, nothing was more natural than that some one should employ machines based on the principle of the formation of stalactites in natural caves, in fact, this is the principle upon which are based the heaters and purifiers built by the Hoppes Manufacturing Company, of Springfield, Ohio.



The system embraces a live steam purifier and an exhaust steam feed-water heater, which are very similar in design, the latter having in addition an oil-separating device and some auxiliary attachments. The structure of these heaters, as shown in Fig. 1, includes a boiler shell, within which, supported by suitable brackets and bars, is a series of curved pans made of steel plate. These pans are placed in one or more tiers, depending upon the size of the heater, and are so designed that after the feed water is let into the top pan it flows over the edges in a thin film and adheres to the under side till the lowest part is reached; it then drops into the next pan, and so on to the bottom of the shell. Steam is admitted direct from the boiler, and is brought in direct contact with the thin sheets of water, causing the water to relax its hold on the impurities in solution, so that these are deposited on the under side of the metal pans.

The pans are made in lengths of from 5 ft. to 6 ft., so that by removing the head of the shell the pans can be readily drawn out, cleaned and returned. Attention is given to the use of asbestos packing, which is placed in a groove under the head and prevents leaking, and also to a swinging arm or crane provided with a trolley wheel, by which the head is swung out of or into position with little outlay of muscular strength.

The live steam purifiers are made in capacity from 50 h.p. to 1000 h.p., and the latter are 5 ft. in diameter and 24½ ft. in length, while the exhaust steam heaters are from 50 h.p. to 5000 h.p., and the dimensions of these largest sizes are 68 ins. x 26½ ft.



The products of the works also include steam separators and oil eliminators bearing the same name as the purifiers.

The works of the company are located in the suburbs of Springfield, and occupy a long one-story brick building with three "L's," two of which extend across a railway siding, so that all unloading and shipping are done under cover. The office occupies a separate building on a slight elevation overlooking the works.

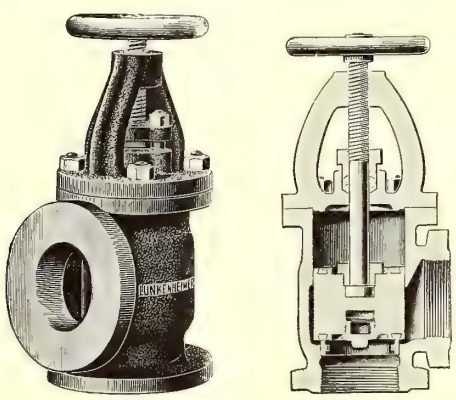
PURIFIER, SHOWING PANS

The stock room, which is 48 ft. x 60 ft., occupies one of the "L's" and here are found great quantities of steel plates of various dimensions and thicknesses, for making the shells and pans. This department is provided with an overhead traveling crane, which runs in every direction, and delivers the plates to the rolls, punches or other machinery in the boiler department, where the laying out

DRILLING CYLINDER OF PURIFIER

and shaping is accomplished. This department is 60 ft. x 100 ft. The erecting department is 60 ft. x 80 ft., and contains a number of interesting tools and appliances designed to facilitate the work; among these is a plate milling machine or planer, on which the plates are planed to a bevel edge by means of a revolving cutter or milling tool. This is a novel machine of its class, as by its use the edges of a plate may be milled to correspond to any desired curve or arch in the plate. This machine was designed and built in the works, and the company contemplates manufacturing them

for the trade. Another interesting and rare tool (Fig. 2) is a drill for tapping the shell after it is finished. The shell or boiler is mounted on low trucks, and is run along the track under the drill, which is supported by two pillars sufficiently high and wide to receive shells of the largest diameter. The cutting tool is arranged to be driven from a separate head, and is so arranged that holes can be drilled at any angle. The equipment has recently been increased by the installation of a large set of plate bending rolls. Stud bolts for fastening the heads are manufactured on a specially designed machine, which cuts a smooth, fine thread on the best of steel bolts. The most striking illustration of the efficiency of the purifiers and heaters manufactured by this establishment are the great number of repeat orders which are constantly being received, and it is very seldom that the company equips a plant with these appliances that it does not get a second order when the capacity of the plant is to be increased.



The present company was organized in 1886, and the affairs are now under the direction of the following officers: John J. Hoppes, president; Robert Johnson, vice-president; J. A. Hayward, treasurer, and A. G. Spencer, secretary.

Iron Body Angle Blow-Off Valves

The iron body blow-off valves, illustrated in this connection, are manufactured by the Lunkenheimer Company, of Cincinnati, and have been employed so extensively by steam users that some particulars of them will be of interest.

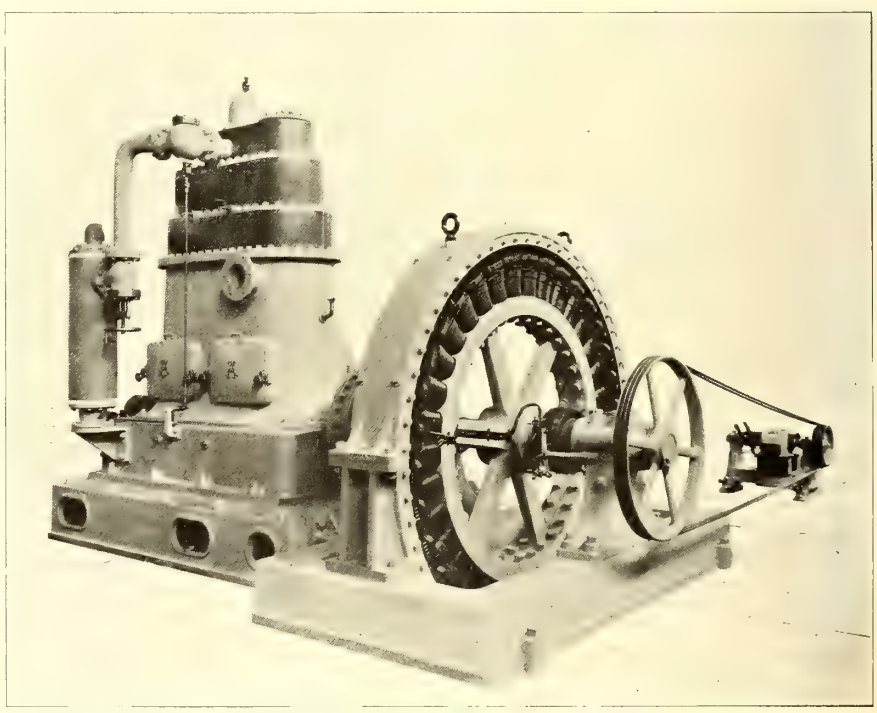
All parts are made of iron, excepting the stem, disc-locknut, disc-plug and seat ring, which are of bronze, while the reversible bearing faces in the iron disc are filled with Babbitt metal.

Reference to the sectional illustration will show that the disc is solid and fits closely in the barrel of the valve shell, so as to prevent scale and sediment from becoming entrapped on top of the disc, thereby preventing it from being readily raised when necessary. The disc is reversible, having two valve or seating faces, which can be changed at will, thereby increasing the durability and efficiency of the valve considerably. These valve or seating faces in the disc consist of dove-tail slots, which are filled with Babbitt metal, and when both are cut or worn out the old Babbitt can be melted out and new metal poured into the slots. The faces can then be faced off, thus renewing the principal wearing parts of this valve, and making the parts as efficient as new. The brass seat ring in the body of the valve can also be renewed when cut or worn.

BLOW-OFF VALVES

To reverse the disc it is only necessary to remove the valve bonnet, and take the entire trimming out of body of valve, then the small plug at the bottom of the disc and disc-locknut around valve stem can be unscrewed. The position of the disc can then be reversed so as to present a perfect bearing face to the seat ring in the shell of the valve.

All valves are carefully made of the best materials, and are thoroughly tested in every particular, all parts are made to gages and are interchangeable, so that any broken or worn out piece can be renewed.



Large Storage Battery Installation at Plymouth, England

A large storage battery has recently been installed at Plymouth, England, by the Tudor Accumulator Company. It is composed of 260 Tudor cells of the type LB 11, and is capable of giving an output of 120 amps. at 480 volts for five hours, i. e., it has a capacity of 288 kw. hours. The boxes are made entirely of lead, which is strengthened by stout horizontal and vertical ribs of antimonial lead. Each cell contains eleven plates, 14 ins. x 12 ins., the positives being ½ in. thick, and the negatives ⅜ in. The complete cell, filled with acid, weighs about 400 lbs. The cells are capable of giving a maximum output of 90 kw.

New High Speed Engine

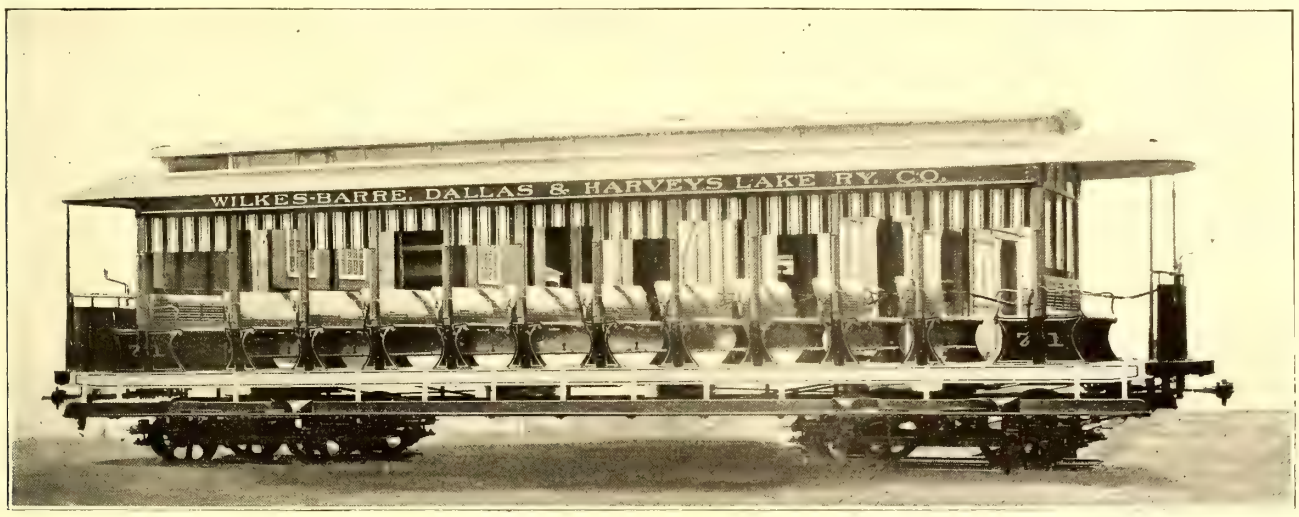
The accompanying illustration shows a new type of high speed engine now being manufactured by Alley & Maclellan, of Glasgow, Scotland, and of which they are making a large number for central stations and other electric lighting and power works.

This engine is of the single acting or constant thrust self-lubricating type, and is arranged with the cylinders placed tandem wise on two cranks at 180 deg. apart, or three cranks set at 120 deg. The valves are of the balanced piston type, and are driven direct by an eccentric on the crank shaft. The lubrication is effected by the most approved method of an oil bath in the crank chamber, the oil being lavishly, yet economically, splashed over all the bearings.

HIGH SPEED ENGINE

Governing can be effected either by a variable expansion governor or by a governor built on the end of the crank shaft, and operating the throttle valve. The latter type is adjustable by hand while running. Very close governing is effected in these engines with either type. The workmanship is of the highest class, and all parts, as far as possible, made to gage or jig. A special point in the construction of these engines is their durability, the wearing surfaces being exceptionally large and thoroughly lubricated.

The illustration shows an engine of 250 i.h.p. direct coupled to an alternating current dynamo, both running at 350 r.p.m., the running being exceptionally good and free from vibration or noise. These engines are made in sizes of 10 h.p. and upwards to 500 h.p.



The Liverpool tramway committee has made application to the City Council for authority to reconstruct and equip with electricity the tramway lines extending from Old Haymarket, along Victoria and North John Streets, to Lord Street. The estimated cost of the work is £6,013.

A Large Trailer

The trailer illustrated in the accompanying engraving is a fourteen-bench open car for the Wilkesbarre, Dallas & Harveys Lake Railway Company. A number of cars of this type have just been completed by the Brill Company, of Philadelphia. The cars are 39 ft. 4 ins. over the crown pieces, and are 7 ft. in extreme width. They are mounted upon No. 23 trucks, with 5-ft. 2-in. wheel base. The wheels are 30 ins. in diameter.

There are ten seats with reversible backs, and four stationary seats. Leather covered chains close the openings between the seats. The ends of the seats are round, and the panels correspond with them, greatly widening the opening at the immediate entrance to the seat. Spring roller curtains come down to the floor, closing the side of the car completely. The inside finish is of cherry and ash, with a three-ply handsomely decorated headlining. There are no alarm gongs, no trap doors nor trolley boards. The grab handles are of ash, set in bronze sockets. There is a five-light cluster set in the center of the car, and four-light clusters at each end, one light being placed under the hood of each platform. The drawbar centers are 30 ins. above the head of the rail. These long cars are arranged to radiate very freely, and they can run round curves of only 30 ft. radius. Such a car gives seating capacity for seventy persons. What its carrying capacity is it would be difficult to say. In some cities cars of this type are often crowded with one hundred or more people. This car, although having so large a capacity, weighs but 18,300 lbs. The trucks themselves weigh less than 4000 lbs. each.

While the car is amply strong for the purpose, the absence of the motors and arrangements for carrying them greatly reduce the total load carried.

FOURTEEN-BENCH TRAIL CAR FOR WILKESBARRE

Feed Pumps as a Specialty

It is a truism that specialization is the note of latter day engineering, and this characteristic of our time is seen more distinctly in auxiliary plants than almost anywhere else. In this field firms are to be found who have devoted their energies to the perfection of a certain portion of engine or boiler room equipment, with the result that concentration and experience have enabled them to take the lead in their respective lines. An instance of this may be cited in the firm of Messrs. G. & J. Weir, Ltd., Cathcart, Glasgow, whose boiler feed pump is the outcome of long experience devoted to the question of boiler feeding and cognate problems. The rise in boiler pressures of recent years, and the increasing adoption of water tube boilers have produced many new and difficult conditions, rendering the familiar crank shaft pump quite unsuited to modern requirements. For many years the duplex pump held the field, but the increased attention now given to the steam consumption and efficiency of auxilaries has gone to show that a more economical type is desirable. For years the Weir direct acting feed pump has been the standard pump in the mercantile marine, and it has been fitted for such enormous boiler installations as those of the "Kaiser Wilhelm der Grosse," "Kaiser Friedrich," "Oceanic," "Campania," "Lucania," etc. For water-tube boiler feeding on Belleville, Thorneycroft, Normand, Babcock & Wilcox, and other installations in H. M. Navy, it is used almost exclusively and is largely adopted by almost every navy afloat. Messrs. Weir have for some time been putting on the market an adaptation of their pump for land boiler feeding, and attention is called herewith to a few of the points of this specialty.

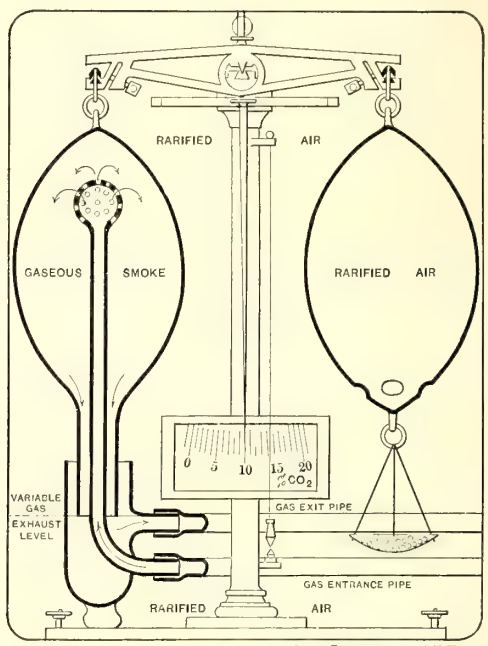
The Weir direct acting feed pump of the single cylinder type, double acting and vertical. It has positive valve gear, actuated from the piston rod, so that there is no dead center, and it starts at any part of the stroke on steam being turned on. The steam valve consists of a main valve and an auxiliary valve, and is arranged to cut off before the end of the stroke. In fact, economy in steam consumption is one of the features of this pump, and it is claimed that in steam economy the Weir single pump is distinctly superior even to the compound duplex pump, while it has also the advantage of fewer moving and working parts, thus requiring less attention and upkeep. Compared to the motor driven pump the balance of advantage is claimed to be also with the Weir pump, as numerous experiments have demonstrated. Under certain conditions, such as when exhausting into the atmosphere and compared with the motor driven pump at full load, the advantage of economy may certainly be on the other side to a slight extent, but the exhaust from the steam pump may be utilized for expansion in the low-pressure cylinder of the main engine, or it may be used to heat the feed water, say by means of a Weir feed water economizer, and in this way the ultimate economy of the Weir pump, it is claimed, exceeds that of the motor driven pump at any speed.. It is, moreover, a much less complicated piece of mechanism than the motor pump, and has fewer points to get out of order. Its first cost is likewise smaller, it takes up less floor space, and does not require expensive or elaborate foundations.

Not only is the design the outcome of long experience in pump problems, but the construction and material of the Weir pump are of the highest grade, and its details have been most carefully studied and perfected. The standard type for land installations has the water end of cast iron, fitted with gun metal liner, gun metal bucket, bronze valves, and bronze valve seats of the Weir patent group type. The pump is compact and neat in appearance, and is an ornament in any engine or boiler room. For small pump installations Messrs. Weir also supply their differential type of feed pump, which is designed for more moderate sized installations. It is single acting on the suction side, and double acting on the discharge side, but is able to run quicker than the ordinary bucket and plunger pump. It is very easily overhauled, as the entire pump barrel may be drawn up along the plunger, thus exposing the bucket rings and the suction valves for examination if desired, and it is capable of feeding boilers up to 200 lbs. pressure.

The works of the firm at Cathcart, Scotland, are thoroughly modern and up-to-date, organized and equipped with the latest

American, British and Continental tools, many of them specially designed for the manufacture of the firm's boiler feeding specialties. Many of the most recent electric light and power stations have adopted the Weir pump, such as The City of London Electric Light Company, The County of London and Brush Provincial Electric Light Company, St. James' & Pall Mall Electric Supply Company, Corporation of Leicester, Corporation of Sunderland, Stafford, Glasgow, Manchester Electric Light stations, etc., etc.

Economical Power Generation



Economy in power generation is constantly receiving greater attention, and street railway and tramway managers are now studying every avenue of expense to learn whether there is any posibility of making a saving, however small, in this or that department. For this reason many engineers in America are looking with great interest on the subject of the use of refuse as a fuel in their power stations, and investigating the successful results secured in this direction in England by the Simplex Destructor manufactured by Meldrum Bros., of Manchester. The principles of this destructor were fully described in the STREET RAILWAY JOURNAL for May and July, 1898; but since the publication of these issues Meldrum Bros. have greatly increased their sales, and their well known device has gained even greater popularity. One of that firm's most recent installations, and one which has just been completed, is at Darwen, Lancashire, where all the power is to be obtained from refuse, and no supplementary boilers are being put in for coal firing. This installation marks the confidence of the authorities that they can rely upon refuse alone for obtaining light and power for tramway purposes.

The manufacture of the refuse destructor, however, forms only a department of the extensive business of Meldrum Bros., who have made a specialty of the construction of a variety of economical machinery for steam uses. Another product for which they have an extensive sale is their mechanical stoker. The results obtained by this stoker are remarkable alike for boiler efficiency, for weight of steam obtained per hour, and for fuel efficiency, i. e., pound of water evaporated per pound of fuel burned. The stoker is said to be the only one that will burn coal dust and (breaze) successfully. It combines forced draft with stoking on the coking principle, with surprising results, as shown by the above test on a Lancashire boiler 30 ft. x 8 ft., which is a sample only, and with results which compare very closely with others. The boiler was fitted with two flues 3 ft. 3 in. diameter, and an economizer was not used during the test. The duration of each test was eight hours continuous running. The heating surface of the boiler was 1000 sq. ft., and the total grate area 35.75 sq. ft.

RECORD OF TESTS MADE WITH STOKER

Kind of coal used (Lancashire)	Arley Nuts.	7 ft. Nuts.	4 ft. Slack
Total water evaporated per hour in lbs.	12625 lbs.	10500 lbs.	8625 lbs.
Water evaporated per sq. ft. heating surface per hour	12.62 lbs.	10.5 lbs.	8.62 lbs.
Water evaporated per lb. of coal as fired	7.65 lbs.	8.18 lbs.	8.12 lbs.
Water evaporated per lb. (from and at 212° F.) per hour	9.09 lbs.	9.57 lbs.	9.35 lbs.
Temperature of feed water entering boiler	63.3° F.	79.1° F.	96.1° F.
Mean steam pressure in boiler	77 lbs.	67.5 lbs.	64.5 lbs.
Weight of coal burnt per hour	1650 lbs.	1283 lbs.	1062.5 lbs.
Weight of coal burnt per hour per sq. ft. of grate	46.15 lbs.	35.89 lbs.	29.72 lbs.
Percentage of heat transferred to boiler	62.96 p. ct.	64.11 p. ct.	65 69 p. ct.
Percentage of CO_2 in flue gases	13.0 p. ct.	11.6 p. ct.	11 0 p. ct.

Still another apparatus manufactured by Meldrum Bros., which has received a most favorable reception from steam engineers, is the Arndt patent coal-saving gas-weighing apparatus. This device is termed an "econometer," and is illustrated herewith. It is a well known fact that for the combustion of a fixed quantity of fuel of a certain quality a definite quantity of atmospheric air is required. If more air than is necessary for perfect combustion is conveyed to the fuel a loss of heat arises, caused by the superfluous air being unnecessarily brought to the high temperature at which the gases leave the steam boiler. How great this loss may be and how small it only need be, may be seen from the table here-

ECONOMETER

with. This table shows the loss of heat and fuel with from 2 to 15 per cent C O_2 in the combustion gases. The proportion of air actually used to the theoretical amount required is, in the case of coal (according to Bunte) $\frac{18.9}{K}$, being the amount per cent of carbonic acid in the gases.

TABLE SHOWING LOSS OF FUEL WITH ADMISSION OF DIFFERENT PERCENTAGES OF AIR IN FURNACE

For Coal of medium quality.

If there is	2	3	4	5	6	7	8	9	10	11	12	13	14	15	Per cent. carbonic acid.
Then the quantity of air passing through the flues is	9.5	6.3	4.7	3.8	3.2	2.7	2.4	2.1	1 9	1.7	1.6	1.5	1.4	1.3	Times the theoretical requirements.
With a surplus supply of air of 30 per cent. or about 10.4 Cub. M. of necessary air per kilo. of fuel, there will still be a further excess of about	6.56	40.0	27.2	20.0	15.2	11.2	8.8	5.6	4.8	3.2	2.4	1.6	0.8	0.0	Cubic metres of superfluous air heated to a temperature of usually 270° Centigrade.
And the loss of fuel at 270 C amounts to	90	60	45	36	30	26	23	20	18	16	15	14	13	12	Per cent.

The "econometer" is designed to indicate the exact percentage of C O_2 in the gases. These are admitted to the left-hand bulb of the scale, and as carbonic acid is about 50 per cent heavier than atmospheric air, the amount and percentage of this gas can be readily determined by reading the scale. Filtering chambers, drying chambers, etc., necessary for obtaining correct results are provided with the equipment.

Absolutely no smoke was made during the whole of the tests.

Another interesting point was the high reading of C O_2 in the chimney gases, as ascertained by the Orsat apparatus, proving little excess of secondary air.

The company has received a number of excellent testimonials to the valve of this forced-draft furnace—among others from Arthur Ellis, M. I. E. E., borough electrical engineer of Bolton; John H. Barker, A. M., I. C. E., general manager of the Cambridge Electric Supply Company, of Cambridge, and Henry W. Bowden, manager and chief engineer of the Kensington Central electrical lighting station.

That some railway companies have already taken precautions to keep their lines open during the coming winter is shown by the fact that since Aug. 1 last, Messrs. Wendell & MacDuffie have taken orders for sixty-three Taunton electric plows and ten sweepers. For so early in the season this is certainly an excellent indication of the value of these machines. The same firm also reports doing a large export business in the many street railway supplies for which they are agents.

The Electric Railway and Tramway Carriage Works at Preston

The opening of the electric railway and tramway car works at Preston, England, last Spring, was an excellent indication of the extent to which electric railroading has gained popularity in that country. The difficulty of obtaining new tramway cars on short or even moderately long notice had long been felt, and with the increasing number of electric roads in the United Kingdom there was a large demand for an extensive addition to the car building facilities of the country. For this reason the support of prominent home capitalists was enlisted, and the extensive works at Preston were the result. The directors of these works are Chairman George Richardson, Richard H. Prestwick, George F. Fry, Robert B. Barningham, Robert S. Boddington, John Kerr and Geoge Flett. The manager of the company is E. A. Stanley, formerly of the Jackson & Sharp Company, of Wilmington, Del., and the secretary, J. Baynes.

The works are close to the Albert Edward Docks, and the River Ribble, and have sidings into them from the London & North Western and the Lancashire & Yorkshire Railways. There is every facility for the receiving and dispatch of materials and goods, whether by sea or land. The buildings are so extensive that of the thirteen acres to which the property extends, from four to five acres are under cover. System and orderly sequence, resulting in efficiency and economy, form the key-note of the whole plant. Beginning at the entrance, and taking those in the south and afterward those on the north, the buildings include the following: To the right of the entrance, general stores; to the left, the offices of the company; at the south end of the ground, a building for cutting and storing timber and lumber; at the north end of the ground, boiler and engine rooms, bogie fitting, machine and smiths' shops, carpentry and erecting shops, paint shop, and pit shop where the numerous pits between the tracks admit of the motors being fitted to the electric cars. The experimental track in the grounds is also a prominent feature.

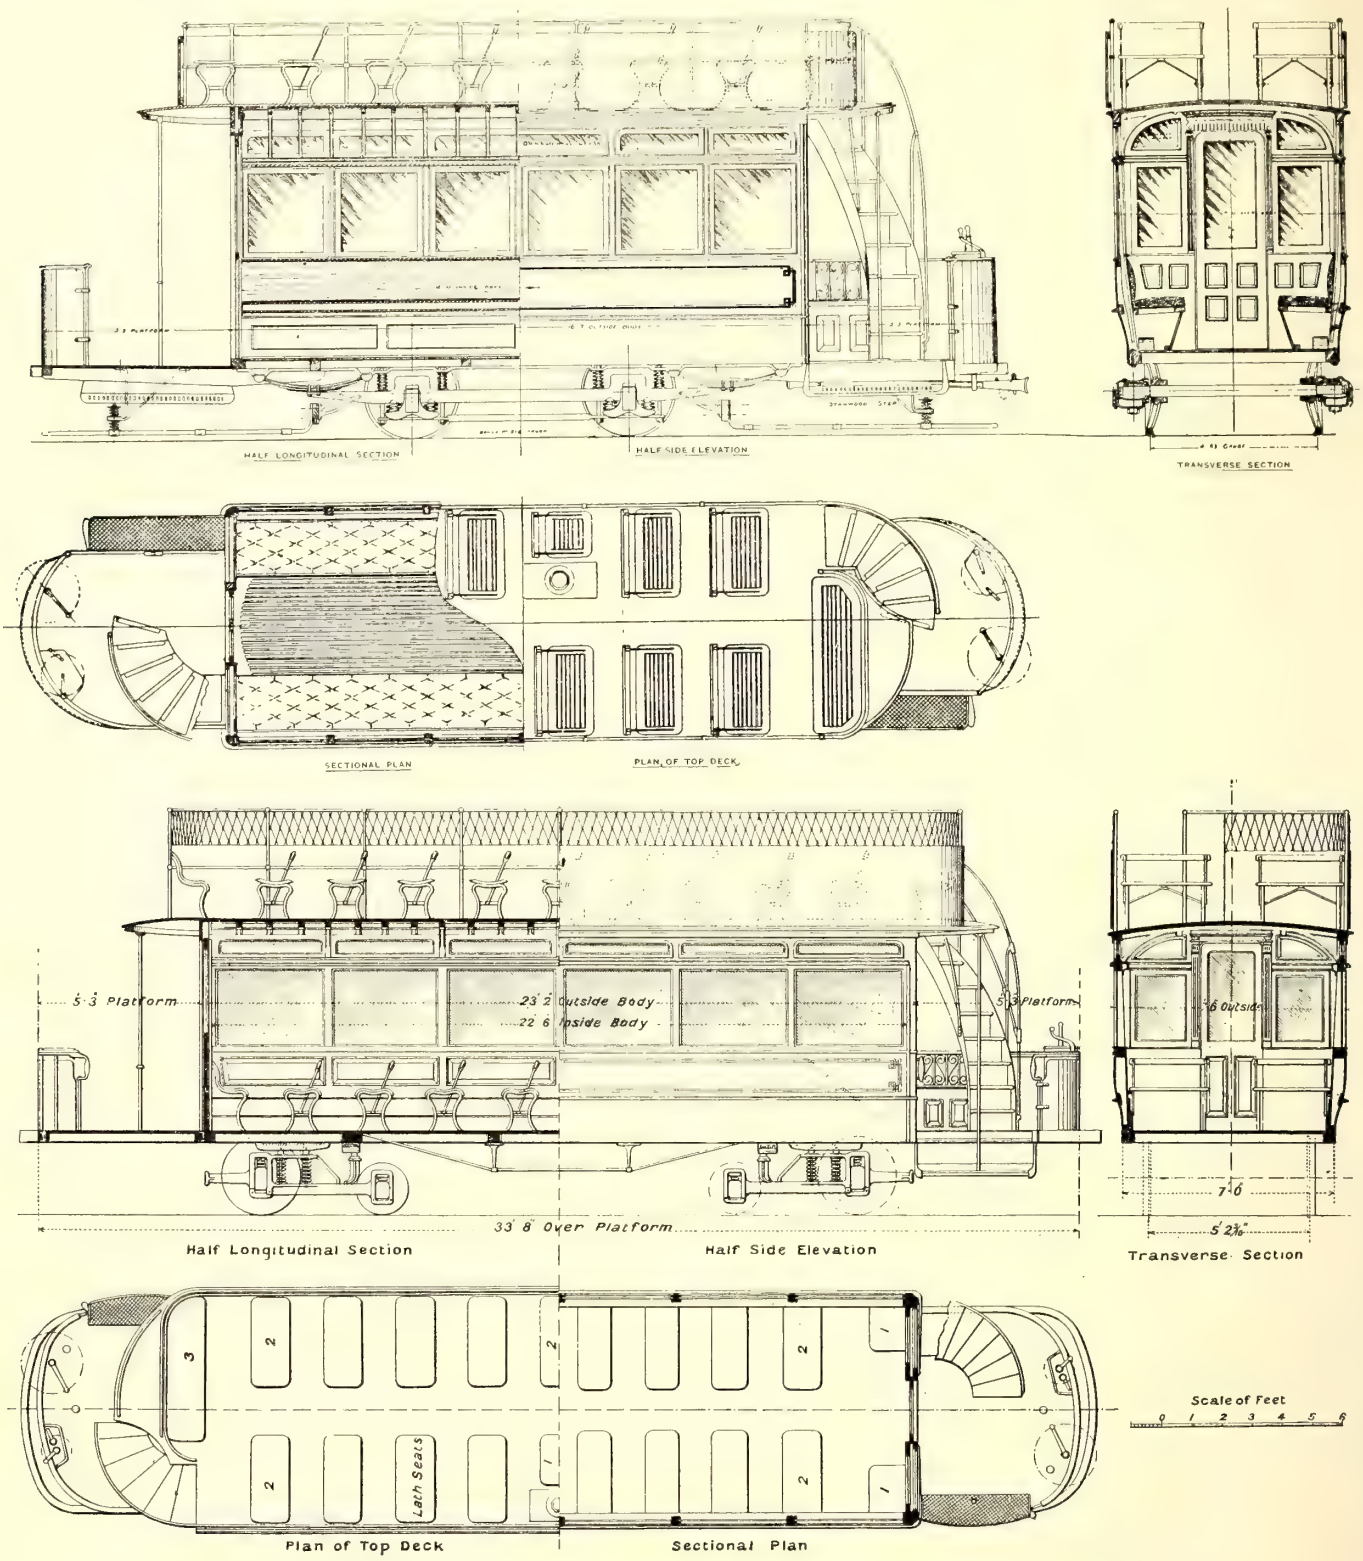
The steam is generated by two Galloway boilers, each 28 ft. long by 7 ft. 6 ins. diameter, and having a nominal rating of 225 h.p. The engine is of the horizontal compound type, with automatic fly-wheel governor, and is coupled direct to a Mather & Platt multipolar dynamo. The size of the engine is 14 in. and 25 in. x 24 in. stroke. Its output is 325 i.h.p. at 150 r.p.m., the steam pressure being 120 lbs. per sq. in. This plant is now being duplicated, and any possible breakdown will thus be avoided.

The main switchboard consists of slate panels, mounted on an iron framework, and from it there are run separate distributing feeders for lighting and for power in each of the shops. The pressure is 230 volts, which is considered the most suitable for combined distribution to motors, incandescent and arc light, and by a special arrangement of the switchboard the dynamo and a storage battery, which under normal conditions are operated in parallel, can be connected in series to a special bus-bar when it is necessary to test motor cars on the experimental track mentioned hereafter.

The storage battery consists of 140 chloride cells, having a capacity of 440 amp. hours, and is intended for use in lighting the buildings during the night, or should it be found necessary to work in one section of the works for a few hours overtime, the motors can be operated from the storage battery, and thus avoid running the main engine.

The whole of the machine tools throughout the works are operated by electric motors. In the case of the larger tools an individual motor is used, but for the smaller machines two or more are grouped together on a single motor. By this arrangement the heavy losses of line shafting are obviated, and at the same time the objection to a larger number of small motors all of different sizes is avoided. Thus throughout the works there are over twenty-five motors, but in only three sizes of 10 h.p., 25 h.p. and 40 h.p., and

GENERAL VIEW OF PRESTON WORKS



END VIEW OF MAIN BUILDINGS, PRESTON

as each size is of the same make and interchangeable, only a minimum quantity of spare parts are required to be kept in stock.

Timber is brought on cars into the store room, which is a plain brick structure 225 ft. long by 50 ft. wide, and one story high. The railway track runs right through the building. At the east end is a log band saw mill where the logs are rapidly sawn into planks of whatever thickness is desired. The mill can deal with logs up to 48 in. in diameter, and from 30 ft. to 40 ft. long. Storage space for an ample stock of timber is provided, a very large portion of which is already occupied with selected and naturally seasoned timber of the highest grade, the fundamental importance of securing and having in stock a sufficient supply of carefully seasoned timber having been one of the first points to receive the attention of the management.

The sawn timber is conveyed from the storage shed on the railway track direct into the wood-working machinery and erecting shops, which occupy the two central bays of the main building. The shops now referred to have light iron truss roofs, are well lighted, and have a concrete floor between each railway track. They are equipped with machines of the latest and best type, which have been obtained from America. Here the timber is sized, shaped, and put together, and as the car body grows it is passed along to the north end of the shop, and then across to the paint shop on the west side, where in the various surface finishing processes, outside and inside, it is worked back southwards to the pits, where the addition of the truck and motors takes place.

In connection with the wood-working machinery an apparatus called a cyclone dust collector has been provided, which by a sys-

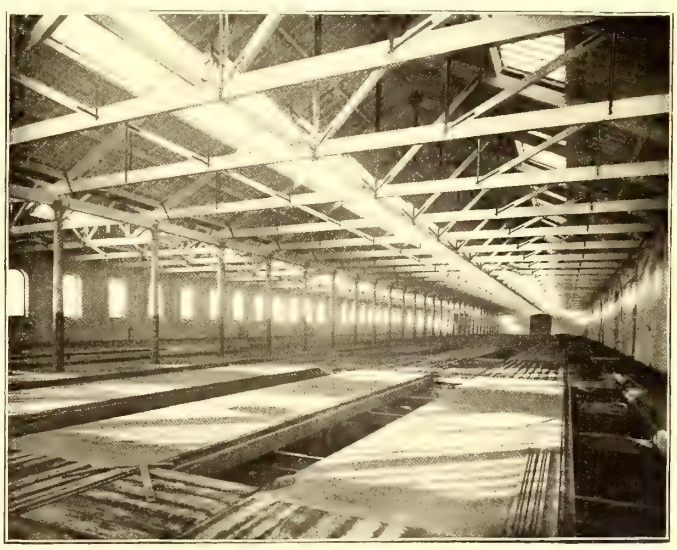
TYPICAL DOUBLE-DECKED SINGLE AND DOUBLE TRUCK CARS RECENTLY BUILT AT PRESTON

tem of piping, conducts all wood dust and shavings to the boiler house, where they are deposited for use as fuel. Good storage capacity is provided for this material close to the furnaces.

Iron and steel materials which have to be forged go round, on coming into the works, to the east side of the buildings and are passed on the railway wagons into the smithy. While the company manufactures trucks for electric cars it is also prepared to supply and fit to the car bodies any make of trucks. When the trucks which are built on the premises are finished they are brought out in front of the bogie shop and taken along by a traverser, which runs along the front of all the shops, to the pits at the end of the paint shop, where they are fitted to the car bodies. The other iron work of the cars is worked northward to completion, and is then passed across to the paint shop and fitted in place. In the iron fitting shop two large galleries run the entire length of the building on each side, and in these a large amount of work is done, while the space below is of course still available. The smaller and lighter machine tools are placed in the galleries, and the heavier are underneath. Nearly all the machinery and machine tools for the iron working part of the establishement have been bought from English makers.

The paint shop requires only little special fitting, but heating arrangements have been provided to keep the temperature uniformly at 65 deg. After the finishing touches are put on the car bodies, they are moved along to the pits where the trucks and wheels are attached, and, in the case of electric cars, which will form the majority of the output, the motors are fitted. There is really but one large pit extending the full breadth of the shop, but between the tracks it is covered over. As there are eight tracks in this shop, and two pit openings in each track, the effect is to give sixteen working pits. The depth is ample, so that the men can conveniently work underneath the cars and get everything properly fixed.

When the cars are mounted, and the electric connections and fittings have been adjusted, they are ready for testing. The car is brought out of the paint shop on to the testing line, part of which also serves, as already described, for bringing the material into the works. The ground is fairly level, though at the east side where it rises a little some cutting was necessary. The track is carefully laid with 56-lb. rails, on creosoted ties, and fully ballasted. Its length is a little over half a mile. Including the fifteen sets of tracks inside the buildings, the total track length of the works is about 2 miles. The testing line is equipped with overhead trolley wires in the usual fashion, as in the case of an electric tramway. Curves of various degrees of sharpness have been provided on the track, so that the trucks may be tested under a variety of conditions, including those of maximum difficulty. The sharpest curve has a radius of 35 ft., and it is obvious that if a car can go round a curve of this sort in the works it will be able to do the same thing in actual service. Further on there is a curve of 50 ft. radius, and subsequently another which is of 90 ft. radius. All severities of curvature are thus provided for. There is no test for gradient, but that is a matter which mainly concerns the power of the motors, and this company does not build motors. It fits the motors which are provided by the electrical manufacturers, and these machines at the present time are thoroughly standard- and tested for the various classes of work which they are intended to perform. The car, having successfully gone through the ordeal of the testing track, is now ready to be put into service.



On the basis of the ordinary size of tramway car with roof seats, the capacity of the works is about 800 cars per annum. Larger cars of the eight-wheeled type, both for electric railways and

STORAGE YARD AT PRESTON

WOOD WORKING DEPARTMENT

PAINT SHOP

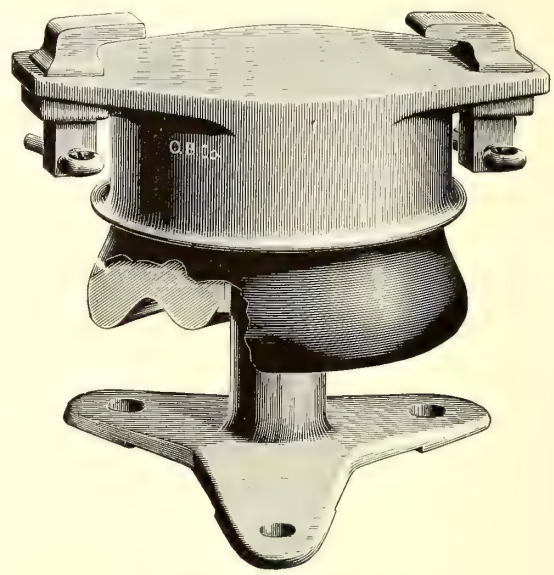
tramways, will be turned out when required, and the company will be able, if necessity arises, to build railway carriages. The number of men employed will range from 600 to 800. The first order undertaken was one of seventy-five cars for the North

ASSEMBLING ROOM

Metropolitan Tramway Company, of London. Since that time the company has built cars for many other roads, including tramways in Aberdeen and West Hartlepool, and the Waterloo & City Underground Railway, of London.

Automatic Lubrication

In most of the large electric power plants which are being built the installation of some system of automatic lubrication for the journals and bearings of the engines and other running machinery is the rule, and not the exception; for electrical engineers now generally admit the saving and economy, as well as the better lubrication, afforded by mechanical means over that when hand lubrication was depended upon. A good idea of the saving secured by automatic lubrication is shown by the record of the Missouri Edison Electric Light Company, of St. Louis. Mr. Wagner, general superintendent of that company, said recently that during the six months or more in which he had had automatic oiling apparatus in operation a saving had been effected of over $300 per month in the cost of oil, and $150 per month in wages. All of the saving in wages was attributed to the use of the oiling system, and about half the saving in oil, the balance being due to a change in the character of the grade of the oil itself. The system used at this station is that of the Siegrist Lubricator Company, of St. Louis, which has made a specialty of the construction of automatic oiling systems, and manufactures not only special oil cups for the use of the system, but also piping, pumps, etc., automatically controlled by special governors to maintain a constant pressure on the pipe lines to which they are connected.



The pumps are usually located in the engine room, and are mounted on a table, the top of which is of iron, polished and japanned black, to give it a bright and lasting finish. On this table are four specially made pumps, two for the engine and generator bearings, and two for the cylinder oil. Only one pump of each set is used at a time, the other being held as a reserve or duplicate to be thrown into service if required. All connections are of polished brass, making this part of the equipment exceedingly ornamental. As will be seen, the system does not depend upon gravity pressure, but upon a high steam pressure. The oil is stored in two tanks, placed one on each side of the table, or wherever desired, and connected to the pumps by suction pipes, which run down to, and under the floor, and then into the tanks. In addition there are two main discharge oil pipe lines, carried usually under the floor to the engines, with branch lines to each bearing on which lubrication is necesary. A valve placed in a convenient place on each branch line controls all the oil on that engine automatically, and the starting or stopping of one or more engines does not affect the others.

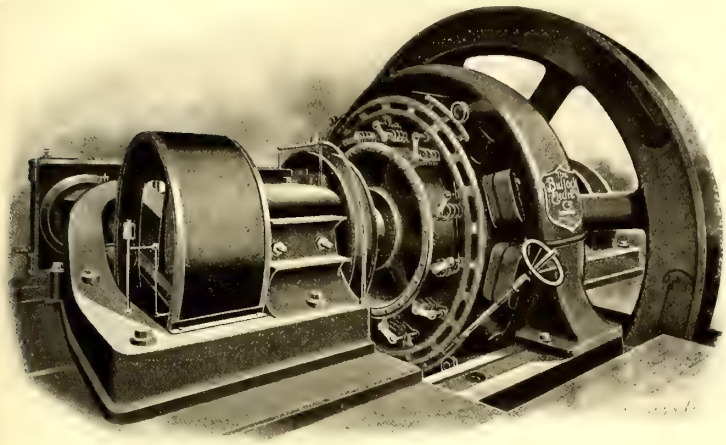
The automatic sight feed iubricators are made extra heavy to stand any steam pressure, and glasses are imported directly from Scotland. They have large, clear openings, with a 1-in. glass and gate valve connections for the free passage of oil. Each lubricator is also furnished with a back connection for steam, which keeps the oil hot, and as well closes the lubricator in case the oil pressure gets below that of the steam. The automatic oil cup is also made extra heavy, and can be regulated by a thumb-screw to give any quantity of oil required. When once set this oil cup requires no attention, unless a different feed of oil is wanted. The system also includes an improved filter, to which the unused oil is returned automatically, after which it is pumped back to the tank. After the oil is taken from the barrel and is put into the tank it is under complete automatic control.

Third Rail Insulator

Frequent inquiries for an insulator adapted for the third rail system have resulted in the Ohio Brass Company, of Mansfield, Ohio, bringing out for the market a device similar to the illustration shown herewith. This is of the same general character as many of its predecessors, but presents several new features which give it originality; in fact, a patent has recently been allowed the Ohio Brass Company upon it.

This insulator consists of a malleable iron standard rigidly secured to an insulating body of vitrified clay, or some similar

THIRD RAIL INSULATOR



material, which is of the proper size and design to support the third rail with safety, and also present sufficient surface leakage of the current over its exterior. Upon this insulating body is fastened a malleable iron cap casting which supports the third rail, and, by means of lugs on each side, holds it in alignment horizontally, but permits vertical play or motion to obviate the trouble arising from the breaking of the insulators, which has occurred in the past, from the rail being secured too rigidly to the insulator.

Head-Lights for Electric Cars

The Multiplex Electric Company has recently published a short catalogue descriptive of the various styles of corrugated reflectors manufactured by it for steam and electric railway cars. These reflectors are spun out of a heavy gage of brass, and their form consists of a series of convex and concave shells, the size and radius varying with the style and kind of light to be used. Each corrugation is a powerful reflector by itself, and the reflector is thereby enabled to produce a light of great intensity. The company also makes a specialty of furnishing these reflectors to persons who desire to substitute them for others which they now have. It also supplies special incandescent lamps for railway head-lights. These lamps have certain features which particularly adapt them for this use. The company also makes oil head-lights.

A New Street Railway Generator

During the ten years of its existence, the Bullock Electric Manufacturing Company, of Cincinnati, has established a high record for its electrical machinery, and Bullock motors and generators have become famous the world over as being thoroughly reliable and up-to-date. As a result the company's business increased to such an extent that in 1898 it determined to erect new

800-KW. GENERATOR

works which were occupied in January of the present year. Encouraged by this success, the company has now determined to enter the railway field. To this end, a complete line of engine type railway generators has been designed up to and including the 800-kw. unit. Bullock railway generators will possess all of the features that have made this company's present standard machines so popular, and also some new features that cannot be found in other machines.

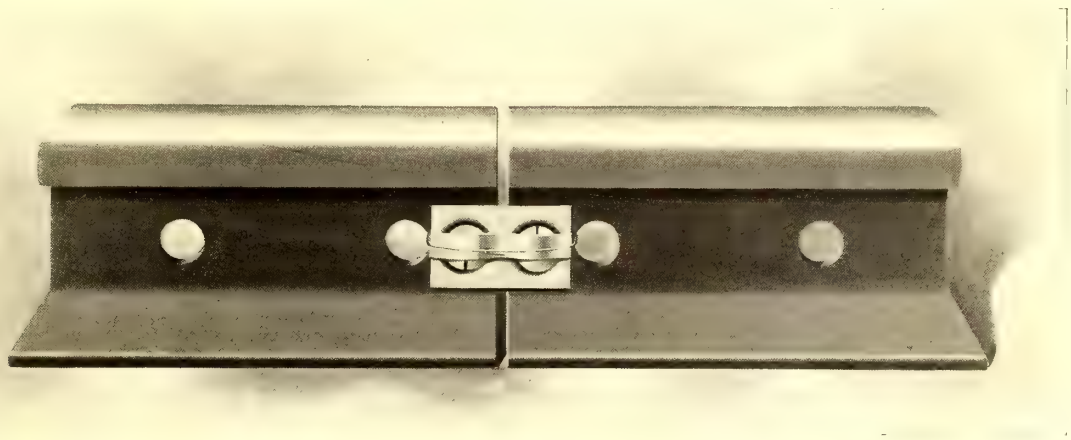
Among the more important may be mentioned a scheme for oscillating the brush holder mechanism in a direction parallel with the shaft. The movement is very slow and results in constantly changing the line of travel over the commutator face and thus removes all tendency to cut or groove the latter. The action is the same as secured by the end play of an armature in a belted generator or that produced by the electro magnetic device used at the ends of shafts on rotary transformers, and which is recognized by engineers as a means of greatly prolonging the life of the commutator.

The pole pieces and coils may be removed without disturbing the yoke or armature, and with two of them removed, it is possible to remove one or more armature coils should repairs be necessary.

The armature coils are made of continuous bars of copper without joints between the commutator connections which materially adds to the life of the machine. These coils are all thoroughly insulated, pressed and baked before being placed on the core, no additional core insulation being necessary.

All armatures are thoroughly ventilated by slots perpendicular to the shaft through which the air rushes when the machine is in operation. A liberal rating permits of constant operation at full load with low temperature rise.

One of the 800-kw. machines has been sold to the Oakland Rapid Transit Company, of Oakland, Cal., and is shown in the engraving. This machine operates at a speed of 80 r.p.m., and at this speed develops 550 volts at no load. It is over-compounded for a rise of 50 volts at full load making the full load voltage 600.



A New Copper Bond

A new type of bond, called the solid copper bond, has been designed by Harold P. Brown. It is not intended to take the place of his plastic bond for heavy duty, but it is intended for loads proportioned to its section. Its compact shape enables it to be sold at a low price.

The solid copper bond is made of a rectangular piece of rolled electric copper, 3 ins. long, ⅛ in. thick (or thicker) and 1½ ins. or more high. A cup-shaped projection is pressed near each end so as to give a contact against rail web close to the end of each rail. Inside the cups is a piece of sheet steel supporting a pair of special steel springs; the steel is used to keep the springs from wearing into copper. These pieces are held together by a small iron strap until the bond is applied when the sharp web on the outside of the spring cuts it away and it enters the angle plate, thus aiding the conductivity of bond.

The entire bond is amalgamated to prevent rusting, and the contact surfaces are covered with the plastic alloy. The springs are proportioned to give a pressure of 1000 lbs. per square inch when the angle plate is bolted up. The bond is always laid out to fit each particular rail and joint and does not interfere with the mechanical fit of angle plate. When in service the springs serve merely as distance pieces so long as the joint is tight; if the nuts loosen or the plate wears, the springs still hold the bond in firm contact. Then tightening the track nuts also tightens the bond. The use of lock washers is advised on the track nuts to keep them fast. The springs then take up merely the wear of the plate.

To apply this bond it is only necessary to brighten the web of the rail beyond the end bolt hole with the usual hand power grinder and emery wheel. The surfaces are then amalgamated by the Edison process and covered with a thin layer of plastic alloy. This unites with the amalgamation of the bond and maintains an electrical contact of low resistance which will not rust.

NEW COPPER BOND

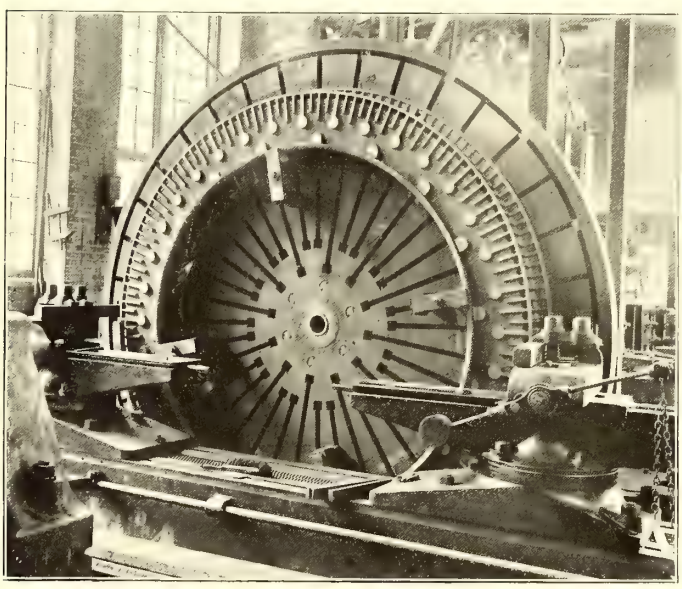
The lubrication afforded by the plastic alloy permits the rails to move in any direction without wearing away any metal of the bond.

The size of the copper will be varied to suit requirements of purchasers, up to the full area of the space between rail web and angle plate, and between end of bolt holes in rail. The manufacturer will not make a smaller size than No. 0000 since less than that amount of material will not give sufficient mechanical strength for durability.

The bond shown has a vertical cross section of more than 0.218 sq. in., while the section of a No. 0000 wire is but 0.166 sq. in. The bond, therefore, has a conductivity equal to one and three-tenths No. 0000 copper wires.

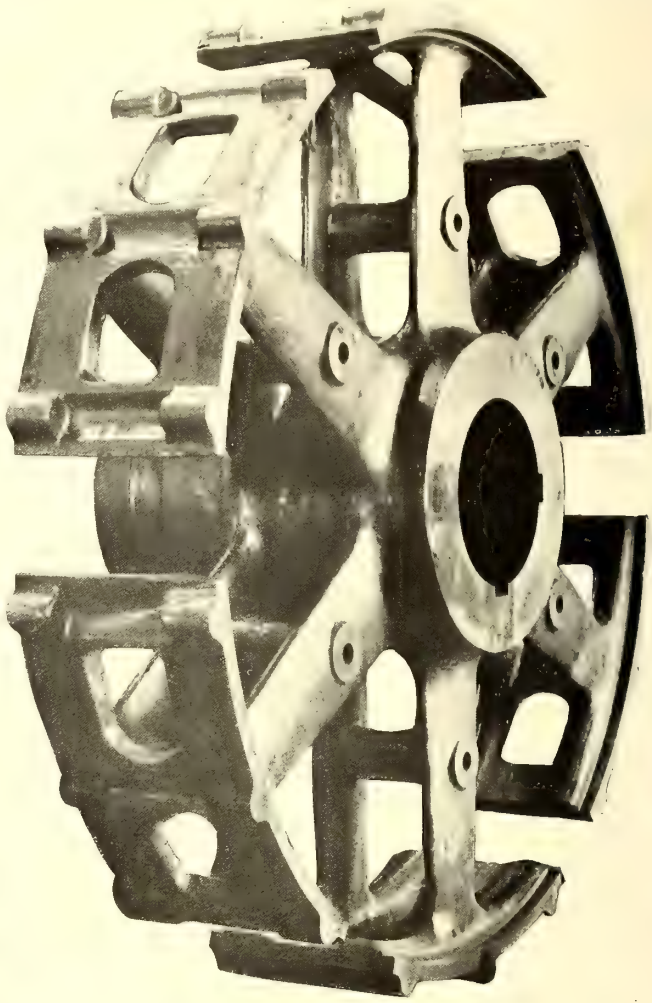
The depth of the special steel spring is varied to suit the clearance between rail and angle plate and is always so proportioned

that the spring is perfectly flat when joint is tight. The steel is made for this purpose and will maintain its tension for years. On covered track in wet or alkaline soil where steel is apt to rust rapidly, both the springs and the sheet steel base, when desired, can be treated with a petroleum compound which will permanently protect them. This, however, will prevent the angle plate from taking any portion of the current through the bond contacts.



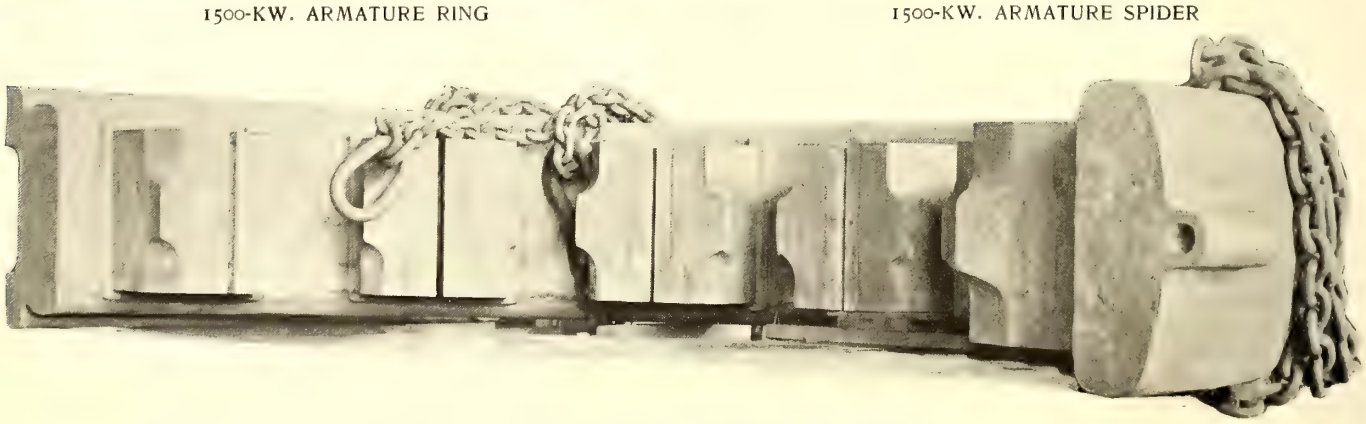
Amalgamated copper bonds of this type (but without the spring feature) have been in satisfactory service for several years. The springs are a safeguard against poor contacts when the joints loosen. As long as the joints are kept tight the bond will do its work. There is no bending nor shearing strain on the copper since the bonds have sliding, lubricated contacts.

Extensive Electrical Works in Chicago



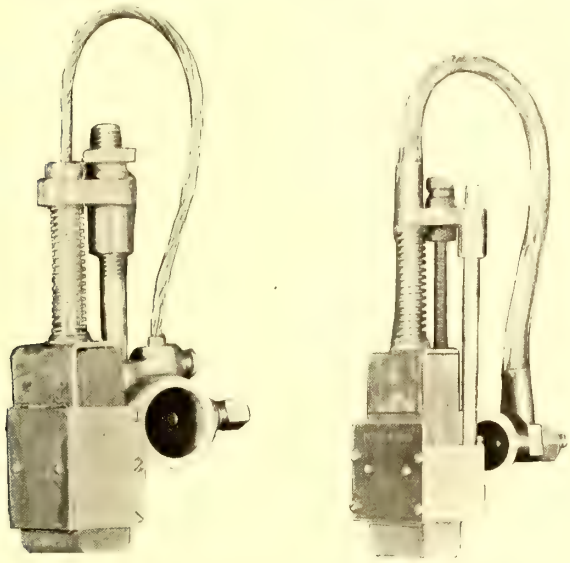
One of the chief points of interest to the delegates of the coming American Street Railway Convention at Chicago, will undoubtedly be the extensive manufacturing works of the Siemens & Halske Company, of America. This company, as is well known, has supplied a very large proportion of the large street railway generators in Chicago, particularly for the Chicago Union Traction Company and Chicago Consolidated Traction Company, operating on the north and west sides of the city. Within the last year, however, the company has been reorganized and has changed in a number of points, the design of its large railway generators. It has also entered extensively into the manufacture of small motors for automobile service, wattmeters and other measuring instruments for all varieties of current, and, in fact, into nearly all classes of electrical machinery, with the exception of street railway motors, in which field the company has not as yet engaged. It is understood, however, that the manufacture of large generators for lighting and power work will be made an important specialty of the company, and as the designs for the improved type of the railway generators have been finished, and as many of these large machines are in various stages of completion at the company's works in Chicago, an inspection of these shops will prove of especial interest to railway managers and engineers. The works, it should be stated, are equipped throughout with the best of modern machinery and orders have been received in such large quantities as to require the operation of the shops day and night during the past summer.

Among the special machines noticed by a representative of the Street Railway Journal during recent trips to the shops, were two 1000-kw. generators, one for the Northwestern Elevated Railway Company, of Chicago, and one intended for use in Kansas City, Mo.

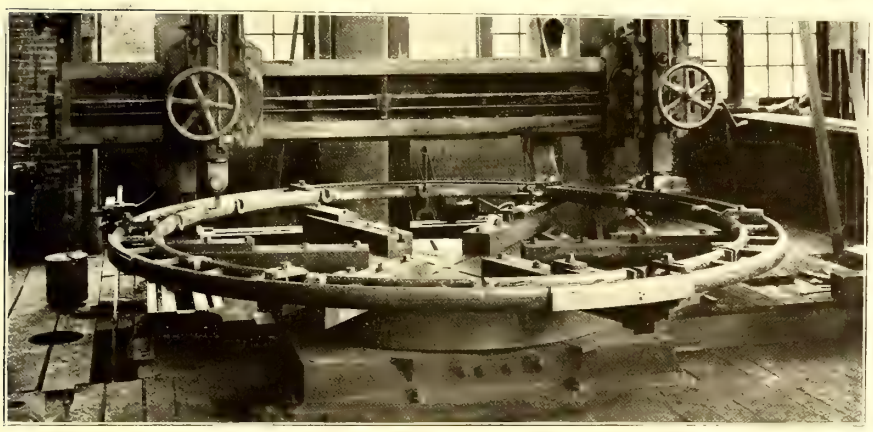


As the company's new design of railway generator will be of the greatest interest to the street railway reader, a description of it in detail will now be given. The magnet frame is a circular yoke of cast steel, divided either horizontally or vertically. The former construction is used for generators to be installed in stations equipped with traveling cranes and the latter where the halves are to be mounted on guides and drawn apart. The field poles differ

1500-KW. ARMATURE RING

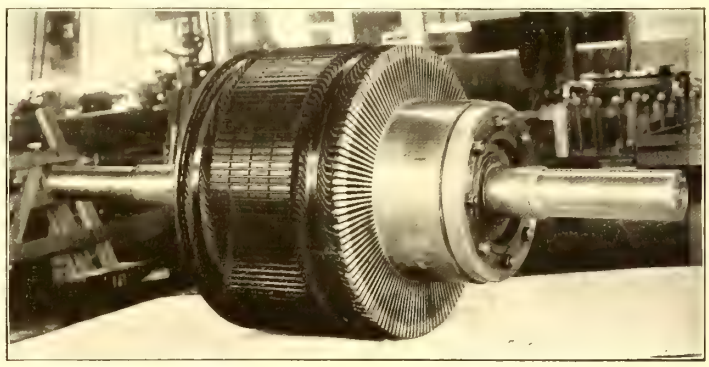


1500-KW. ARMATURE SPIDER



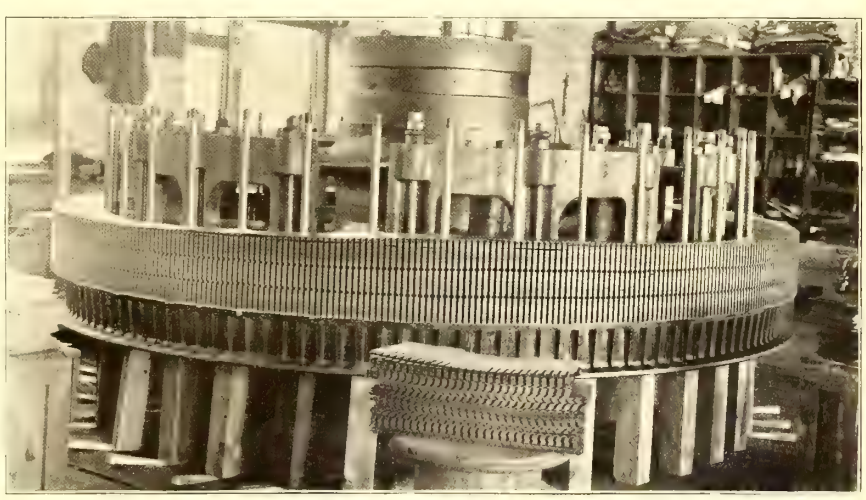
1500-KW. MAGNET FRAME, SHOWING POLE PIECES

from the ordinary praetice, in being shoeless, and are so proportioned that perfect commutation can be obtained, it is claimed, under all conditions, from no load to 50 per cent overload. The field coils are wound on spools and heavily insulated, the shunt and series coils being wound separately, so that either may be removed from the spool without disturbing the other. Any spool can so be removed from its pole piece by taking out the retaining non-magnet pins which hold it in position. The series coil is so proportioned and located that it acts directly on the armature coils, eliminating the distortion of the field magnetism, and thus obviating the sparking. This method is claimed to be much more advantageous than that in which the main effect of the series coil is upon the iron of the field magnets, pole, shoes, etc., because the latter when saturated change their permeability as the load increases. The field coils are machine wound and protected with heavy insulation at points of mechanical strain. The pillow block and bearings are separate castings, fitted to the main casting on an arc. This allows the armature to be accurately centered and perfect alignment to be permanently maintained.



BRUSH HOLDERS

TURNING A 1500-KW. BRUSH HOLDER SUPPORTING RING

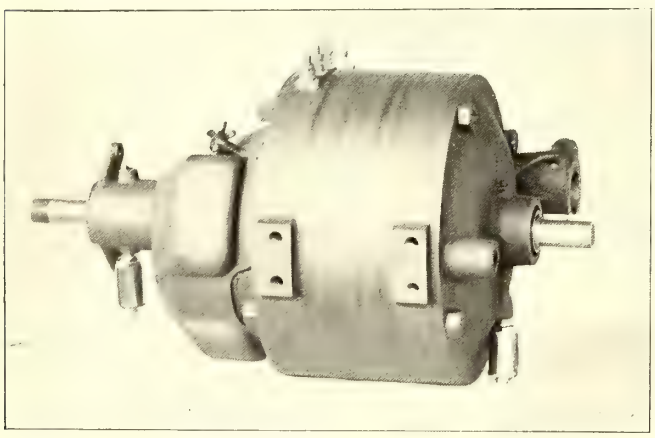


The armature is of the drum type, having a uniformly toothed core, built up of laminations of special soft steel and assembled in a cast iron frame. The first point which strikes the observer in looking at this core is its great surface and diameter, with comparatively little depth. The object of this is two-fold. The first reason is to permit the use of a large number of commutator bars, with consequent small differences of potential between adjoining bars. As a matter of fact, the maximum difference of potential between adjoining bars in the company's latest 550-volt generator is not over 6 volts or 7 volts. The second object of this construction is to secure good ventilation. In fact this object, to which we will refer to more particularly later in connection with the construction of the armature spiders, has been very carefully followed in the construction of all parts of the machine. Air ducts radiate frequently through the laminations outward from the center and provide a constant and effective ventilation. The armature windings are all copper bars, formed, insulated and tested before application. They are placed in the slots and rigidly held in position by wedges, no band wires being used. This method of construction, while it decreases the loss due to armature resistance, reduces heating to a minimum and increases the efficiency of the machine. All connections between the armature and commutator bars are soldered.

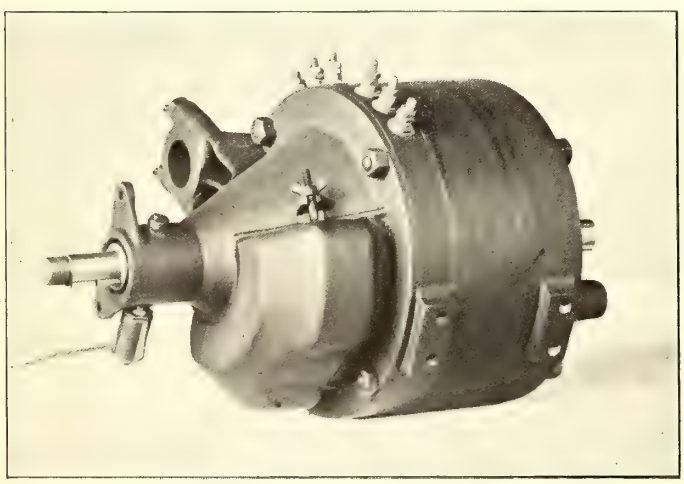
ARMATURE FOR 50-KW. GENERATOR

The armature spider itself is cast solid, and is pressed over the shaft, to which it is also keyed. The spokes are so designed that the spider shall be self-ventilating and arranged to throw blasts of air through the armature air ducts against the field coils.

The commutator is of extra large diameter, though not located outside of the armature coils and field, as with the original Siemens & Halske machines. The commutator segments are built up on a shell extension of the armature frame, and the maximum number of bars is employed, only one turn per coil being used. The bars themselves are of hard drawn copper and are held in position by a special retaining holder, which allows any bar to be readily removed without disturbing the balance of the commutator. The only wear on the commutator is the friction of the brushes.



CONNECTING A 1500-KW. ARMATURE CORE

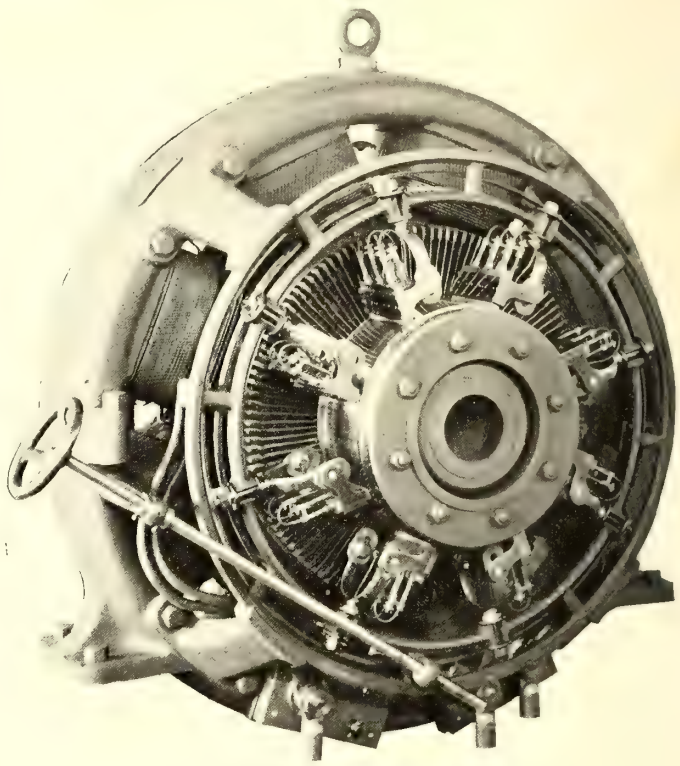


The bearings are self-oiling and self-aligning. The oil is automatically raised from the reservoir in the pillow block to the shaft and distributed evenly by the ducts in the bearing shell over the entire bearing.

The brushes and holders are of special type, invented by Mr. Churchward, chief engineer of the company, and designed to secure constant pressure of the brushes against the commutator, together with the minimum drop in voltage between the commutator and the generator leads, due to electrical resistance. Carbon brushes which are self-feeding, self-adjusting and independently adjustable, are used. They are located radially to the commutator as shown in the accompanying engraving. Their pressure against the commutator is kept constant by a spiral spring, insulated so that its tension is not varied by heat. Attached to the outer end of the brush is a brass rod, to which the lead is soldered, making the path for the current of the lowest possible resistance. The generator lead itself is made up of a vast number of No. 36 copper wires, which give enough flexibility to take up all vibrations of the brush. On the large generators the brush holders themselves are carried on a substantial ring supported from brackets bolted to the frame. By means of a hand wheel and worm gear all of the brushes may be shifted simultaneously. The construction of all these parts is shown in the accompanying engravings.

All of the engine type of generators made by the company are carefully tested during construction and after completion, and no machine is accepted for shipment unless it has withstood the full series of tests prescribed by the company's engineer. All tests are made much more severe than the machines are likely to meet under actual conditions of service.

Special attention is given in these tests to temperature readings and no machine is sent out in which, after a continuous run of



AUTOMOBILE MOTORS

ten hours of full rated load, the temperature of the armature and field wires has risen more than 40 degs. centigrade above that of the surrounding atmosphere. The company also designs its engine type of generators to operate for one-half hour at 25 per cent over load and for a shorter time at 35 per cent over load without injurious heating. All parts of the machines are also made to gage and are interchangeable.

In the manufacture of automobile motors, in which many railway companies are now taking special interest, Siemens & Halske Company, of America, has made rapid progress. An inspection of the company's work shows many of these motors in process of construction and ready for shipment, and the automobile department has a capacity of 125 motors a week. Special attention has been given to the design of these motors. To secure maximum output with minimum weight, the fields are made up of laminated iron. The armatures are of the drum type and the brushes of the same radial pattern as that used on the larger generators. The motors are four pole machines and are generally of 2 kw. and de-

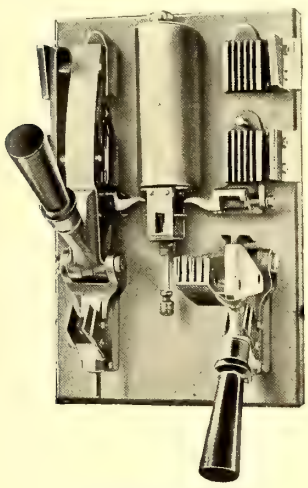
50-KW. DIRECT CONNECTED GENERATOR

signed to run at 800 r.p.m. maximum. They are tested to 300 per cent over load, which must be carried with a rise of not more than 65 degs. centigrade, and are designated to run continuously at 4 h.p. with a rise of not more than 40 degs. centigrade. Another important department of the company's works is the manufacture of boosters and rotary converters. The former are built for both motors and engine driving and the latter with a special mechanical attachment which prevents hunting and pumping, while not reducing the efficiency.

Among the rotary converters noticed in the works during a recent tour of inspection, was some for the Wyoming Valley Electric Company, Wilkesbarre, Pa. These converters form a part of a third order recently given this company for this class of machines, a good indication that satisfaction has been given by them. The company also has a large business in the manufacture of electric lighting apparatus, including enclosed arc lamps and wattmeters. The former are a design of Thomas Duncan, and have proved so popular that the meter department has had to be increased several times to keep up with the orders.

The foundry department alone of the company is most extensive. The company makes all its own brass, copper, iron and steel castings, and its foundry has a capacity of 50 tons a day.

The officers of this company are Isaac L. Rice, president; Charles S. Knight, vice-president and general manager; Williard T. Block, secretary and treasurer; chief engineer, Alexander Churchward. Mr. Knight, under whose general supervision all the work is turned out, is well known in electrical circles and has had many years of experience in the manufacture of electrical apparatus. Mr. Knight became interested in the Fort Wayne Electric Company, of Fort Wayne, Ind., in 1881; later when this company was placed in the hands of a receiver he became director in the new company, the Fort Wayne Electric Corporation; this connection continued until Feb. 1, 1899, when he accepted his present position. Messrs. Churchward, Duncan, Sessions, with many others of the Fort Wayne Company, also became con-



nected with the Siemens & Halske Company, thereby securing to said company such patents as were owned or controlled by the parties above specified in addition to the many secured from the parent company.

Ward-Leonard Circuit Breakers

The illustration, herewith, shows the Ward-Leonard circuit breaker which has come into very extensive use, although it has been on the market only about two years. Prominent among the concerns who use this circuit breaker is the United States Navy, which was quick to appreciate its important advantages.

This circuit breaker has two independent switch arms, each of which has an individual handle and an individual latch. Both latches are simultaneously tripped by a common plunger in case of overload. In closing the circuit breaker the operator first closes one switch and it is held closed by its latch. He then closes the second switch, which is in series with the first one in the same circuit. If an overload or short circuit condition exists upon the circuit when the operator attempts to close the second switch and establish the circuit, the plunger of the iron clad solenoid magnet instantly releases the latch of the switch, which was closed first, and it instantly opens the circuit. It is therefore impossible to close this circuit breaker except when the condition of the circuit is normal and there is no danger of damaging the apparatus in circuit or the operator when this circuit breaker is used.

A novel and important feature is the so-called hammer blow. Each switch has really two arms on the same pivot; one arm carries the switch blades and the other the handle and the roller

CIRCUIT BREAKER

EXHAUST HEAD

which engages with the switch; this latter, or "hammer arm," has a spring constantly tending to move it outward so as to open the switch. When the hammer is released by the plunger of the solenoid upon overload it is moved freely by the action of the spring through an angle of about 20 degs., when it engages with the switch arm and delivers to the latter a strong hammer-like blow which starts the switch blades surely and quickly, even though the friction of rest between the switch blades and their jaws is very great; the spring then rapidly opens the switch. It will be noted that by this novel feature the reliability of action of the switch is very greatly increased, and also that at the time of opening the switch the switch blades are moving at an extremely rapid rate, instead of slowly as in the case of other types where the spring has to accelerate from rest a large mass of material against a strong friction. On this account the arcing is reduced to a minimum. The final arc occurs on auxiliary carbon contacts so as to insure freedom from any arcing at the copper switch contacts.

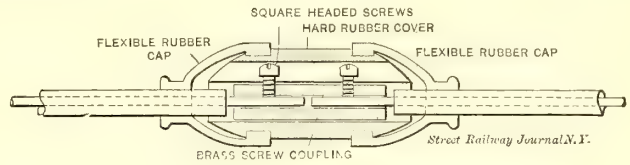
For railway work, where overloads and short circuits are so frequently met, this circuit breaker gives the greatest possible safety to the apparatus and the operator in closing the circuit breaker after it has been automatically opened by overload.

When this type of circuit breaker is used the auxiliary hand switch which is customarily placed in series with the old type of circuit breaker is entirely unnecessary and thus a considerable saving of space on the switchboard is effected.

A nice mechanical point is that when the circuit breaker is open it does not extend outward from the switchboard any farther than when it is closed, which is an important point, as the central station operators are continually passing before the circuit breakers in close proximity to them where the old type in opening might cause serious injury to the operator. The circuit breakers are finished throughout in polished copper and present a very handsome appearance on the switchboard.

A New Form of Exhaust Head

One of the important features of a modern steam plant is an exhaust steam pipe head. To be effective it must thoroughly separate the water from the steam, and thereby prevent the constant spraying of roofs and walls with consequent deterioration and expensive repairs. In the form of exhaust head built by the B. F. Sturtevant Company, Boston, Mass., and illustrated herewith, the principle of centrifugal force is utilized to secure perfect separation.



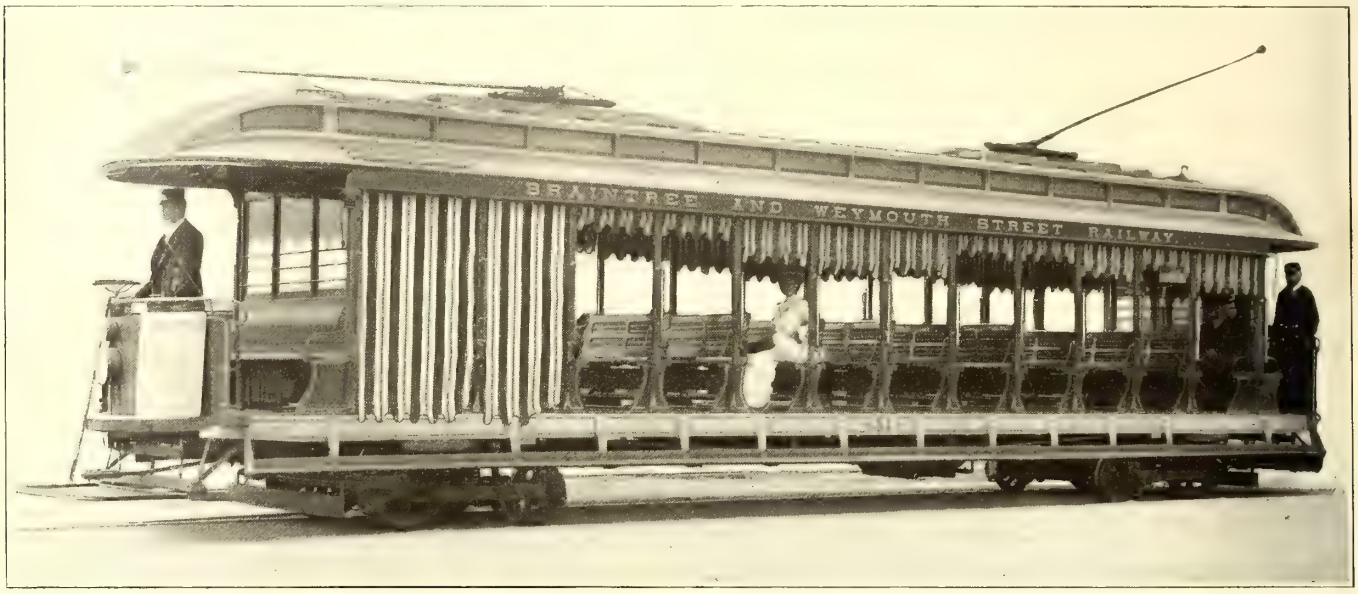
Dry exhaust steam weighs only .038 lb. per cubic foot, while water of the same temperature weighs 59.36 lbs. per cubic foot. It is therefore evident that inasmuch as centrifugal force is proportional to the weight of bodies in motion, the water will be thrown outward with $\frac{59.36}{.038}$ equals 1562 times the force exerted upon the steam. In the Sturtevant exhaust head the steam passes up the interior pipes, is discharged tangentially close to the shell, and is thereby given a whirling vigorous motion. The entrained water—likewise the oil—flies outward, strikes the cool side and trickles down to the outlet at the bottom. The steam, now perfectly dry, finds ready escape through the central opening above. The action is positive and absolute. Perfect separation must be the result.

These heads are built in sizes to fit pipes from 1 in. to 20 ins. All sizes above 10 ins. are flanged instead of tapped.

New Insulating Connector

It is well known that the old method of making the two-way connections of motor leads is a great consumer of time, and on a road where there are many motors the aggregate amount of time required for making and disconnecting these leads is considerable. To overcome this difficulty is the object of the connector illustrated in this connection. It is intended not only to avoid the use of tape, but also to produce an insulating jacket that can be easily attached and removed, and at the same time constitute an absolutely tight and waterproof joint.

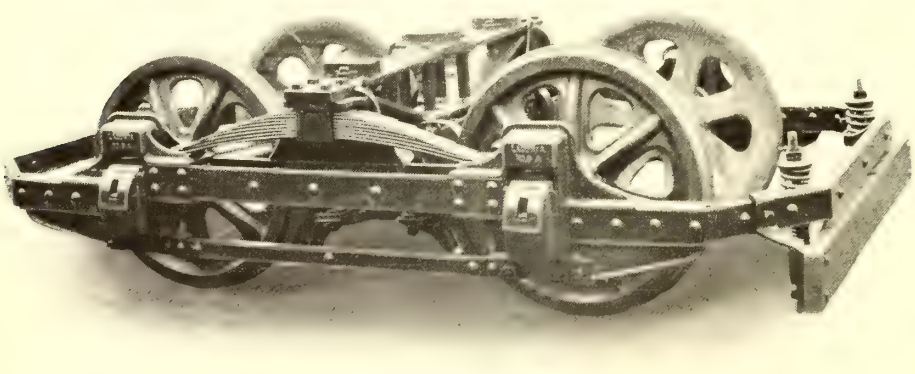
The connector consists of three parts, viz.: a brass sleeve with two square-headed screws at each end and surrounded by a stiff rubber jacket, and two soft rubber jackets, one for each end of the joint. The method of making the connection is then as follows: The soft rubber caps are slipped over the ends of the wires, as shown, but bent backwards. The wire terminals are then inserted in each end of the sleeve and held in position by screwing down the set-screws. The soft rubber caps are then rolled back over the jacket, completely covering all the metal parts. The advantage of using square-headed screws is that they cannot work loose in the jacket and let the wires drop out, as the sides of the



CONNECTOR FOR MOTOR LEADS

insulator are flush with the sides of the screws. These screws are also easily tightened, as common pliers can be used as well as a screw-driver.

The device illustrated is manufactured by C. S. Knowles, of Boston, who makes a specialty of street railway supplies to meet requirements. Among the specialties in which Mr. Knowles deals are cotton and linen hose, oil and electric headlights, paper for insulating purposes, tape, glass and porcelain insulators, trolley wires, carbon brushes, wires, cables, etc.



Handsome Cars for the Braintree & Weymouth Street Railway

The accompanying engraving shows an attractive fifteen-bench open car, of which a number have recently been built for the Braintree & Weymouth Street Railway Company by the Laconia Car Company Works, of Boston. This car, which is the standard fifteen-bench open car of the Laconia Company, has proved very popular on some of the electric railways where large crowds are carried. It measures 45 ft. 6 ins. over bumpers. The width of the car over posts is 7 ft. 3 ins. The distance between seats in the center of the car is 33⅝ ins., and the distance between seats at the end 45⅜ ins. The car is built with closed ends, in each of which are three sashes, dropping into pockets. The car is attractively finished, and has a monitor extending the full length of the car over the dashers. The side curtains are arranged to reach to the floor; all inside trimmings are of solid bronze, highly polished; the inside finish of the car is of white ash; the ceilings are of white beech, and the seats of maple.

15-BENCH OPEN CAR FOR BRAINTREE

The second engraving shows a new type of double truck recently placed on the market by the Laconia Car Company. This truck has been tested under the cars of a number of electric railway companies, and is giving excellent satisfaction, especially on roads having short radius curves. The truck is built compact in order to have a short wheel base, and has center-bearing elliptic springs outside the motor extension, allowing for one or two motors, and inside hung brakes, with either adjustable or solid brake heads. The brake mechanism is extremely powerful, and yet simple in construction, and all parts of the brake are extremely simple and strong, and when worn can be easily replaced.

NEW DOUBLE TRUCK

Large Chicago Mica Company

As a result of business enterprise and eternal hustle, for which Chicago and her business men are noted, she claims the leading house in America in mica and electrical insulation, which is of paramount importance to the street railway fraternity, as without perfect insulation railway equipment is useless. William H. Sills, one of the oldest and best known men in the trade, who has been supplying his many friends and customers with mica since 1885, was joined in 1897 by Clarence B. Wisner, well known in Chicago as the West Pullman banker, and these young men as the managers of the W. H. Sills Mica Company have, by the judicious use of capital and sound business acumen, rapidly forced their way to the front.

The business of this company requires in its various departments a force of 200 people, and one of its secrets of success is in the thorough organization of its work and the care shown in the selection of its executive force. The business is divided into four departments, viz.: mining, electrical mica, micabeston and stove mica.

Its mining department is under the supervision of Charles Guertin, whose office is at Ottawa, Canada. He is also in charge of the Canadian branch. The Saint Anthony mine, located at Gracefield, Quebec, is the largest and most famous mica mine in Canada and is owned by this company. It is equipped with modern steam mining machinery and 100 people are employed in mining and preparing its product for the market. The mine is worked day and night and its product is equal to that of all other mines in Canada. Its electrical mica department is in charge of Henry Velten, a man thoroughly conversant with every feature of the electrical mica trade. He keeps a force of forty men busy to prepare the orders received by his department.

Its micabeston department has for its superintendent William Cooper, an expert workman, who has done much toward bringing manufactured mica insulation to its present high efficiency, and the trade mark "Micabeston" is a guarantee of the excellence and high standard of the article on which it is found. Mr. Cooper has from forty to fifty people constantly employed in making micabeston plates, flexible plates, cloth, segments, rings, tubing, armature slots, washers, etc. Its stove mica department is in the hands of Charles Going, who has been with the house for years.

The company occupies the entire second floor of 60, 62 and 64

Michigan Avenue, and from here its principal business is transacted. Its New York office is located in the Mills Building, with A. L. Wisner in charge to look after the needs of its Eastern customers. In addition to this, the company has agencies in London, Berlin and Calcutta, India, through each of which large

MICA MINE AT GRACEVILLE, QUEBEC

quantities of Indian and other foreign micas are purchased.

The W. H. Sills Mica Company claims to be the largest importer of mica in the United States. Its shipments from Canada alone are

WORKS OF THE SILLS MICA CO.

one car each month and quite often two cars per month, and a car will hold a fortune in itself of material, running into dollars for each pound. The product of this house is distributed to manufacturers and street railways and dealers from Berlin, Germany, to Tokio, Japan, and its trade is constantly growing.

The Lete Mediterranea railway authorities have awarded the Thomson-Houston Company the contract for the conversion of the railways between Naples and Castellamare, Frascati and Rome, and Milan and Gallarate, into electric lines.

Car Cleaning

The subject of car cleaning has been given a good deal of attention recently by the master car builders and superintendents of motive power, representing the steam railroads of the country, and it has been shown not only that a great deal of attention has been devoted by these officials to that subject, but also that some of the most natural suppositions on the subject of car cleaning are erroneous. The large number of cars owned by a steam railroad system makes the subject of car cleaning one to which considerable attention must naturally be given. The advantages from the traffic standpoint, of perfectly clean cars on steam railroads are well recognized, but it is perhaps not so well recognized a fact that frequent cleaning of cars when properly done actually preserves the inside and outside finish, and as a result the cars do not have to be sent as often to the repair shop. It is said that on some roads the saving made in this direction more than pays the entire cost of cleaning. Again, a perfectly clean equipment is usually found a most profitable investment, as well as an attractive advertisement.

The Modoc Soap Company, of Cincinnati, Ohio, has made a specialty of the manufacture of soap and cleaning compounds for railroad cars; in fact, this company is at present supplying over four-fifths of the steam roads of this country, and is also gradually extending its trade among the street railways.

Among the street railway companies using the Modoc soap and car cleaner is the Paterson Railway Company, of Paterson, N. J., the general manager of which, M. R. McAdoo, spoke of the soap in a recent issue of the Street Railway Journal, in terms of the highest commendation. After one year of careful cleaning he reported that the expense of revarnishing the cars was reduced one-half. This more than repaid all the expenses; in addition to which the company always had most attractively clean cars at its disposal. The Consolidated Railway Company, of Grand Rapids, Mich., and the Birmingham Railway & Electric Company, of Birmingham, Ala., have also found this material most satisfactory.

Mr. Johnson, president of the Consolidated Street Railway Company of Grand Rapids, says: "We warm the water enough to take the chill off, and put in enough Modoc soap to make a weak suds; then take a sponge or soft brush and wash the inside of our cars twice a week. In this way all stains or grease spots are removed from the woodwork and the car is left in a very clean and presentable condition. We are very well satisfied with our use of the material."

The Modoc Soap Company publishes a set of instructions in regard to the use of its soap and cleaner, and which embodies the best experience with it on steam railroads, and which will be found useful as a guide to its use in cleaning street cars.

Additions at St. Joseph, Mich.

The St. Joseph & Benton Harbor Electric Railway & Light Company has in the last nine months completed an additional brick boiler room to its station, and has increased the general efficiency of its system by the installation of one 300-h.p. Babcock & Wilcox water tube boiler, one 250-h.p. tandem compound condensing engine, one 120-h.p. Brush arc light machine, one 2000-light General Electric alternator, one 300-h.p. Worthington condenser, six open trail cars, three open motor cars, and an electric sweeper. The company has secured a contract to light and heat the county court house and jails, having demonstrated to the satisfaction of the city authorities that they could furnish the necessary light and heat for three years at $1,100 less than it would cost the county to do it from their own plant, by comparison with their own figures. A 5000-gal. tank, 50 ft. high, with automatic sprinklers, has been erected at the car barn for fire protection.

A New Enterprise in Germany

The firm H. H. Böker & Company, Berlin, W., to whose extensive works frequent reference has been made in these columns, has extended its business in a direction which warrants special mention at this time. As previously stated, this firm has undertaken to introduce in Germany American street railway appliances, which were formerly handled by the Bergische-Stahl-Industrie, of Remscheid, including the brakes of the Standard Air Brake Company, of New York. Since then the firm has made arrangements to act as agents of the St. Louis Car Company for the sale of its cars. The entire wood work of the cars is finished at St. Louis, and shipped to Germany, where it is assembled in the shops of H. H. Böker & Company, where from eight to ten cars can be turned out per week. The works are located at Grosse Lichterfelde-Lankwitz, and connected with the Anhalt railway by a siding. The cars are made according to measurements furnished by the consumer, and, according to American practice, wood is used extensively in places where German manufacturers employ iron or other material. It should further be stated that in none of the cars manufactured by H. H. Böker & Company is paint used for interior decorations; all ceilings, doors and panels are of highly polished natural wood, the principal wood employed being bird's eye maple, mahogany and cherry.

H. H. Böker & Company are now completing an order received from the Grosse Berliner Strassenbahn Gesellschaft, and by arrangements made with the Bergische-Stahl-Industrie, of Remscheid, they are in a position to furnish completely equipped cars by using the trucks made by that company.

WORKS OF H. H. BOKER AT GROSSE-LICHTERFELDE

Machine for Tearing up Old Track

The accompanying engraving shows a new machine for tearing up old track, designed and patented by George W. Baumhoff and Otto Schmid of the United Railways Company, of St. Louis, Lindell Division. This machine, with three men, will tear up nearly 2 miles of track in one day and breaks the rail in any lengths, usually about 4 ft. to 8 ft. in length.

It is not only a great labor saving device for the actual work of tearing up the track, but by breaking the rail in small pieces the rail is made less expensive to load and haul, and commands about $1 per ton more for scrap than rail in full lengths.

The rail shown in accompanying engraving is section U, 78-lb., 6-in. Johnson rail, but this machine has broken 7-in. rail and is capable of breaking 9-in. sections or larger. The United Railways Company, of St. Louis, has torn up 7 miles of track with this machine during the last three weeks. It is especially adapted for tearing up welded track. All the track taken up has been old track, which has been in use for some eight years and which is to be replaced by new track.

MACHINE FOR TEARING UP OLD TRACK—ST. LOUIS

Toledo, Fremont & Norwalk Electric Railroad

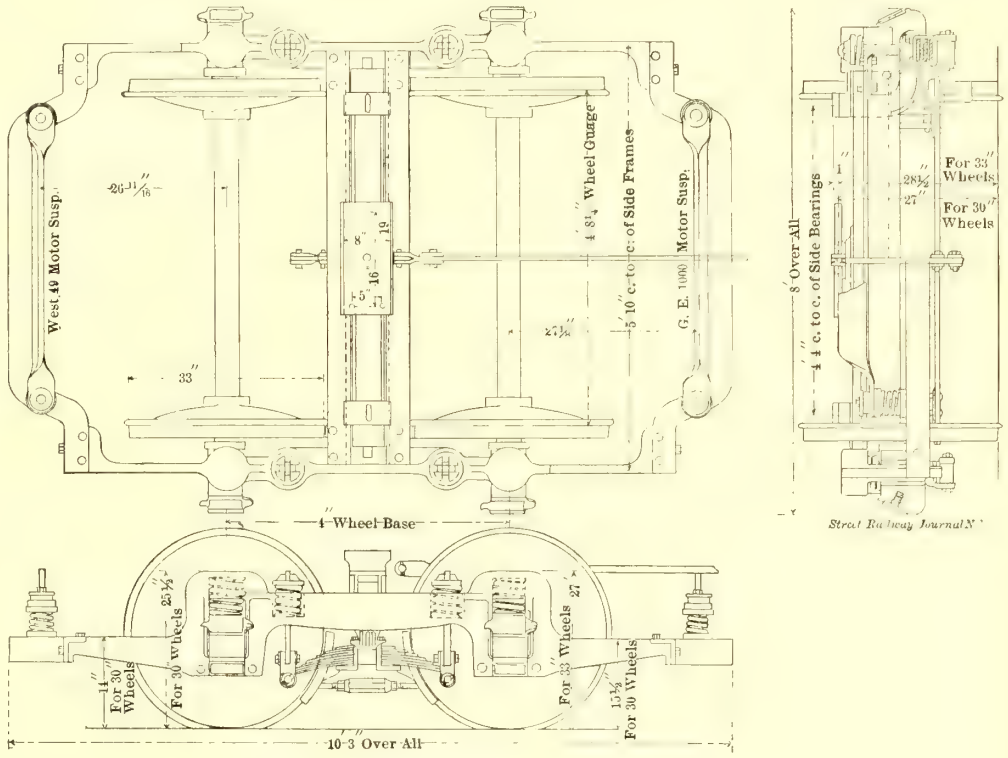
Announcement was made last month that contracts were closed for construction of a 60-mile electric road to connect Toledo with Norwalk, Ohio. The construction will be carried out by Westinghouse, Church, Kerr & Company, who will act as engineers, architects and contractors for the new line.

The three-phase alternating system will be employed for power distribution. The power stations will be erected at Fremont, and the current transmitted at a high voltage in either direction. The power station will be furnished with five 300-h.p. Babcock & Wilcox boilers, equipped with Roney mechanical stokers and coal and ash handling machinery. Two 4000-h.p. Worthington jet condensers will be installed as will also the Westinghouse mechanical draft system, feed water heaters, purifiers, etc. Four Westinghouse Columbian type engines will be direct-connected to four 500-kw. Westinghouse "engine type" three-phase generators, each engine with its generator being mounted upon a massive bed plate, insuring accuracy and permanency of alignment. Two 9 ins. and 15 ins. x 9 ins. Westinghouse single acting compound engines will be direct-connected to two 30-kw. exciter generators.

In addition to the Fremont central power station six sub-stations will be built about equi-distant from each other along the line of the railroad, while a seventh sub-station will be provided within the power house at Fremont. The current will be transmitted to the sub-stations at about 15,000 volts. Each sub-station will be equipped with three step-down transformers and two rotary converters, together with a switchboard and controlling ap-

paratus, and will be connected by feeders with the trolley line and direct current feeders.

The roadbed will be very substantially constructed, as it is intended to run the cars at a speed upward of 40 miles an hour.



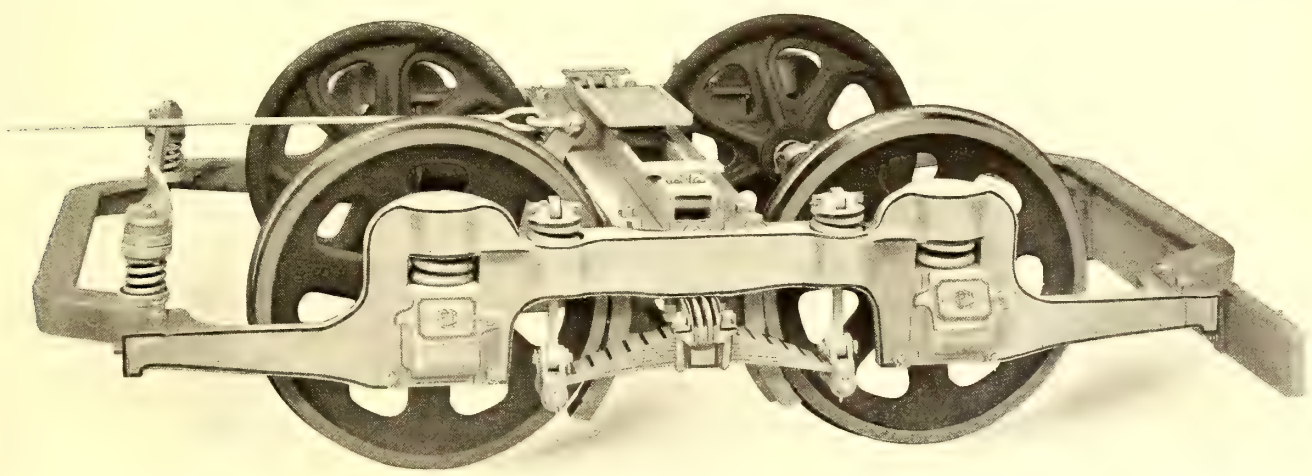
By adopting the alternating current it is possible to supply the entire 60 miles of the Toledo, Fremont & Norwalk Electric Railroad from one central power station. The saving in copper wire alone by using a high tension transmission is estimated at considerably more than $100,000.

The power plant at Fremont is designed to admit of ready extension without destroying the symmetry of its design. The building will have a fireproof roof and a traveling crane will span the engine room. The sub-stations will be arranged so that they will be operated with very little extra attention, being combined with passenger and freight stations.

The No. 14-B-3 Double Truck

The Peckham Truck Company has recently added to its well known series of trucks for all conditions of railway service, another truck, designed for use under double truck cars, on roads having short radius curves. This truck, which is known as the No. 14-B-3, has a short wheel base, with outside hung motors and swinging bolster, and is built exceedingly compact.

This truck is composed of cast steel side frames, two 4-in. x 4-in. x ¾-in. angles forming the end cross sills, and two 4-in. x 6-in. x ¾-in. angles forming the transom, between which the bolster plays. Each of these four angles is secured to each side frame by two ⅞-in. turn bolts, which are driven into holes reamed through the angle iron and casting after the truck has been erected, thus insuring an accurate and positive fit of bolts and angles and making a very rigid construction to maintain the truck in square.

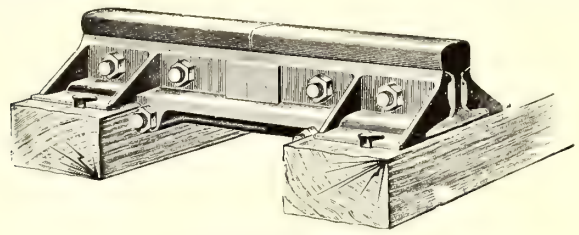


PLAN AND ELEVATIONS OF NO. 14-B-3 TRUCK

The side frames and all other parts of the truck, as well, are proportioned to carry with safety a load of 30,000 lbs. per truck. The cast steel in these side frames is capable of standing the following tests: A 3-ft. 4-in. square bar can be bent cold and the bend closed tight without breaking off. The minimum strength of this steel is 5500 lbs. per sq. in.

The bolster is carried on two half elliptic springs which in turn are carried by coil equalizer springs. Large coil springs are also placed over each journal box, making three separate sets of springs between the rail and car body and assuring a very easy and steady riding car under all conditions of load. The journal boxes are of ample size to provide for a large space for receiving packing.

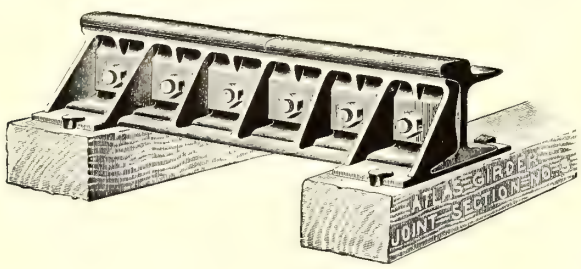
The brake beams of this truck are placed between the wheels instead of outside and with this construction the beams are out of the way of the motor, which is also carried outside of the axles to enable the truck to be built with a wheel base of 4 ft. The location of the brakes between the wheels simplifies it to the last degree, as the whole rigging outside of the shoes, bolts and hangers, consists of but eight pieces, one live lever, one turnbuckle, one turnbuckle jaw, one dead lever, one dead lever jaw, one live lever jaw and two brake beams.



THE NO. 14-B-3 SHORT WHEEL BASE DOUBLE TRUCK

On account of its very few parts the operation of this brake is very quick and powerful, and there is no lost motion to be taken up before the shoes are applied to the wheels.

The Union Railway Company, of New York, has made application for permission to extend the lines of the New York, White Plains & Mamaroneck branch through Tarrytown.



The Atlas Rail Joint

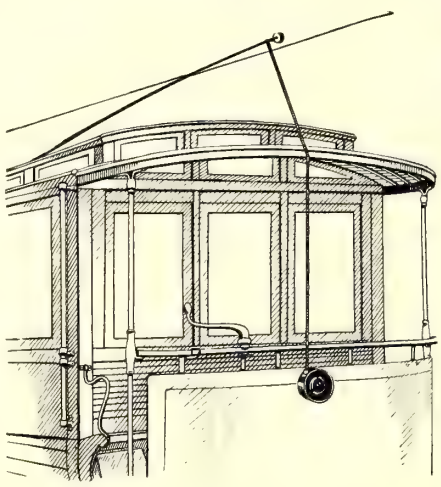
The subject of rail joints is one upon which a great deal of thought has been bestowed by both steam and street railway engineers. A good joint should be able to resist the vertical, lateral and longitudinal forces produced by passing wheel loads, and, where there is expansion and contraction, the strains and stresses of these forces also. Where ordinary angle plates are used, the first indication of any weakness in the plate is the flattening of

SUSPENDED RAIL JOINT

the plate and the points of bearing, allowing the ends of the rails to sink down and the result is the bar has a tendency to buckle. These facts show that the great need in a joint is large bearing surface to resist the pounding of the vertical wheel loads, as

NO. 5 JOINT

well as great vertical strength immediately beneath the connection of the rails. The necessity of reducing joint troubles has caused street railway managers to install 60-ft. rails to a large extent, but while these reduce the number of joints one-half, the remaining joints are just as liable to defect.



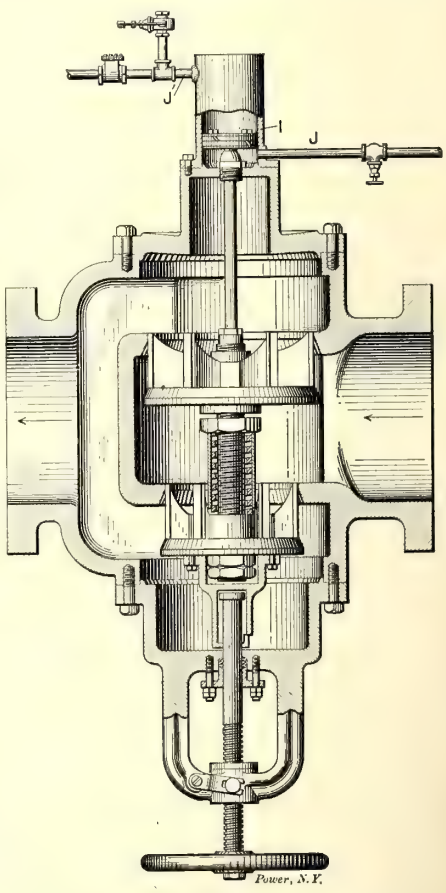
In the Atlas joint these weaknesses are overcome by giving, in addition to the splice bar bearing surface, a re-enforcement both on the outside and inside of plate, extending several inches past the connection of the rails, also a continuous bearing of metal around the lower flange and beneath the base, forming a bed plate for the base of the rail to bear on. This continuous metal forms an inclined clamp, in which the foot flange of the rail is held in a firm grip, any wear being taken up by the tightening of the bolts beneath. Views of the Atlas "Suspended" joint, applied to T rails, shown herewith, as is also the Atlas No. 5 girder joint. This is similar to the standard suspended joint, except that any splice bar may be used on the inside

The lateral force is overcome by the continuous strip of metal extended around and beneath the foot flange, and by the addition of braces extending from the flange of joint at the head to the edge of the tie plate, and in the suspended joint by the truss. The longitudinal force or the force which has a tendency to pull the rails apart on account of the creeping of the track is provided for by using in addition to the four bolts through the web of the rail, the two bolts beneath, causing the ends of the rail to be tightly gripped. These bolts beneath butt against the tie, thereby preventing the creeping of the rails and the damage to spikes.

The Atlas joint is made as a tie, suspended or compromise joint, and can be made to fit any style and weight of rails. It is composed of the best grade of malleable iron and is guaranteed to prolong the life of the rail and to hold up the rail as long as it is run over.

Trolley Pole Catcher and Reel

The engraving below shows a trolley-pole catcher and reel manufactured by Wilson & Company, of Brooklyn. The object of the device is, of course, to prevent the trolley pole from breaking down the span wires in case it should slip on the trolley wire. If this should happen the reel acts, drawing down the trolley pole below the level of the wire. The engraving shows the general arrangement of the device. The company has recently published a brochure giving a number of testimonials to the value of the device from prominent railway managers.



TROLLEY POLE CATCHER

Automatic Safety Shut-Off Valve

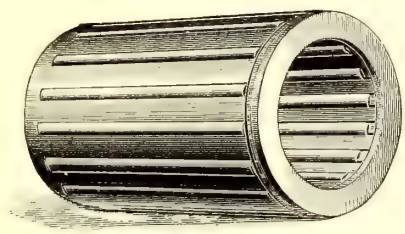
The automatic safety valve illustrated herewith has recently been placed on the market by the Locke Regulator Company, of Salem, Mass., and is designed to automatically shut off the steam from the boilers whenever there is a break at the main or at th engine sufficient to slightly reduce the steam pressure. This is accomplished by means of a steam cylinder and piston connected to a double valve, there being a pipe connected with this cylinder below the piston and running to near the steam boilers, always maintaining the boiler pressure at this point. Another pipe is then connected with the top of the cylinder above the piston and run along the steam main entering it just outside of the throttle valve of the engine. It will be seen that as long as the pressure remains nearly equal above and below the piston, the shut-off valve will remain open, but when the pressure is reduced in the chamber above the piston, as it will be when there is a breakage in the pipe, the pressure will force up the piston and close the valve.

Although this valve is under the control of the steam, which, in opening, would be liable to do damage on account of the sudden action of the steam on the piston, at the same time it is connected with the screw and wheel. This makes it a perfect hand shut-off valve, which takes the place of the ordinary valve on the main pipe, it being in every respect just as convenient to use, notwithstanding that the piston of the steam cylinder is also connected with it.

AUTOMATIC SAFETY SHUT-OFF VALVE

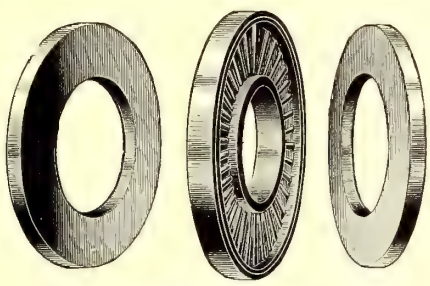
It may also be used to stop the engine in case of accident from any part of the mill. It has been used to cut out a boiler from the rest of the battery whenever a flue or section is blown out, thus preventing a shut-down.

New Type of Filter



The accompanying illustration shows one of the new famous waste oil refining and purifying filters, built by the Famous Filter Company, of St. Louis, Mo., and installed in the plant of the Imperial Electric Light, Heat & Power Company, in St. Louis. This apparatus has a storage capacity of fourteen barrels, and a purifying capacity of 150 gallons per day, and embodies some new features in purifying waste oil in large power plants.

The waste oil, together with all water from the piston rod and valve stem leakages, is led from the engines by pipes directly into the separator, which separates the water and oil, and automatically discharges the water into the sewer and the oil into the removable strainer in the oil filter proper. From the strainer the oil is discharged into the refining chamber of the filter. In this refining chamber the oil is safely and properly thinned by hot air by means of the air-jacket and steam jacket combination embodied in this filter.



In the refining chamber all the minute carbon and suspended impurities are positively separated from the oil and precipitated on the bottom of this chamber, whence they are readily withdrawn once a day through the dirt faucets. In this manner the waste oil is first thoroughly strained, then positively settled and refined, and fully 90 per cent of the impurities are extracted before the oil overflows from the refining chamber into the filtering chamber.

OIL FILTER

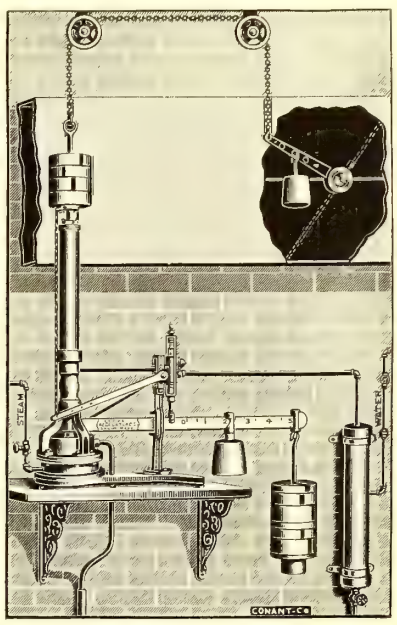
SLEEVE CONTAINING BEARINGS

ROLLER BEARINGS FOR END THRUST

The oil then gradually filters through a large area of compressed white waste and a muslin cloth cover over a perforated cone; this it does by capillary action, by which all the lighter impurities are extracted from the oil. The purified and refined oil is then led into the clean oil storage tank, whence it is pumped into the Siegrist automatic oiling system, and distributed over the bearings.

The manufacturers guarantee that this oil filter furnishes, continuously, absolutely clean and bright oil, and have introduced a simple and accurate method of testing the work of their filter by furnishing a clean oil indicator with every apparatus. With this indicator the clean condition of the purified oil is inspected through a strong magnifying glass.

Roller Bearings for Street Railway Cars



It seems strange to many people that roller bearings have not been applied to railway cars to a greater extent than they have in the past. That there is no inherent difficulty in their application is shown by the instances in which they have been used, and the fallacy of the claim sometimes made that the rattle and jar to which a railway car is subjected would prevent their employment is shown by the extent to which ball bearings, a much more delicate mechanism, have been employed on vehicles of other types.

The Mossberg Roller Bearings Company, of 6 Victoria Street, London, has devoted special attention to the subject of roller bearings for machinery of all kinds, and has obtained satisfactory results in the way of economy of power. The company is now prepared to engage in the railway field, and anticipates that the same saving that has been shown through the use of their bearings in industrial plants will follow their application to railway vehicles.

The bearings consist of a bronze sleeve containing a series of hardened and ground steel rollers. These bearings, being wholly self-contained, can be removed from an axle while the rollers remain intact with the sleeve. They run on hardened and ground steel surfaces, thus insuring durability, and the company guarantees a saving of from 10 per cent to 33 per cent in the power used. This saving varies according to the different conditions under which the bearings are applied, and the tests the company has made on different classes of machines seem to indicate that its estimated economy is by no means exaggerated.

Hydraulic Damper Regulator

The Locke damper regulator has been referred to frequently in these columns, but as no description has ever been published as to the details of its working, some particulars on this subject may be of interest. The arrangement of the apparatus can be seen from the accompanying engraving. The power used to operate the damper is water. The admission of the water is controlled by a small valve, which is attached to and operated by the lever of the steam weighing device, shown at the left of the engraving, and which vibrates with every pulsation of steam. Whenever the steam pressure increases a fraction of a pound the beam is raised enough to open a passage for the water to the damper motor, which moves the damper just enough to correct the steam pressure. A special cut-off device closes the water valve after it has been opened by the rise of steam pressure, and holds the damper partially open, moving it back and forth from ⅛ in. to ½ in., on so light a change of pressure as not to be noticed on the steam gage.

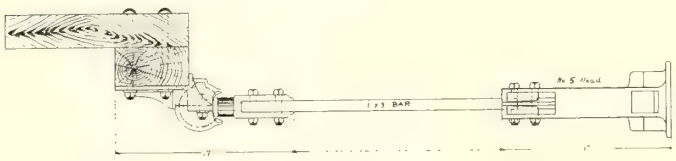
DAMPER REGULATOR

This regulator, which is manufactured by the Locke Regulator Company, of Salem, Mass., has been widely adopted by steam users, especially in electric power stations, where the need of a regulator of this kind is accentuated by the varying load.

The County Central Street Railway Company, of Easton, has been incorporated, with a capital stock of $30,000, to construct an electric railway from near Bethlehem and Easton, to Farmersville and Hallo, a distance of 5 miles. The directors of the company are: F. W. Leinbach, of Alvin Hill; T. M. Dodson, C. A. Wolle and George H. Wolle, of Bethlehem; G. A. Schneebeli, of Nazareth; Andrew S. Keck, of Allentown, and C. R. Horn.

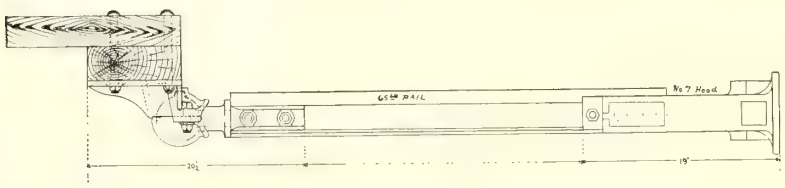
Fender Views

Among the most interesting exhibits to be seen at the Chicago convention will be that of the Hipwood-Barrett Car & Vehicle Fender Company. The exhibit will include a large fender mounted upon a car platform, and a model showing the working of this fender, a mutoscopic picture of a recent test made at Newtonville, Mass.



FENDER IN OPERATION

This picture will illustrate the fender on an approaching car, running at the rate of 15 miles an hour. The fender is dropped, and picks up first a small dummy, which is lying upon the track, arms extended toward the car, and then 15 ft. further picks up dummy standing, and both are held in bed of fender until car is stopped. The engraving herewith shows one view of the set.



This is the first time that a moving picture of an actual test of a car fender was ever shown at a convention.

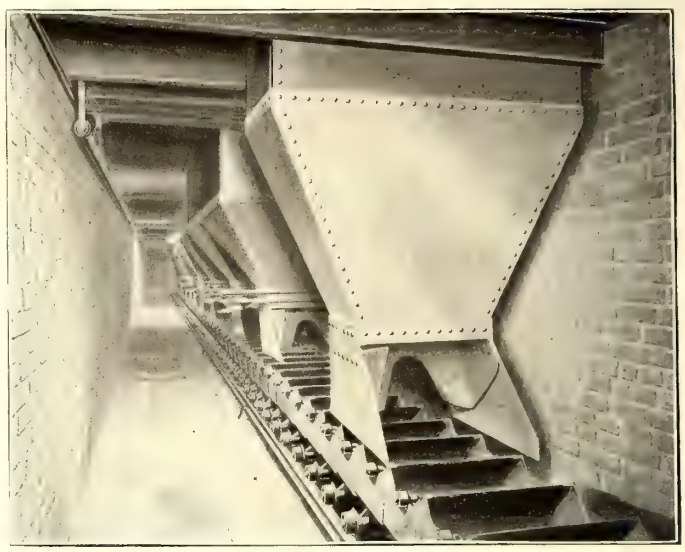
Automatic Couplers

The accompanying engravings represent two out of eleven sizes of automatic couplings, built by the W. T. Van Dorn Company, for all classes of street and elevated railroads. These couplings have now been in use seven years. More than 50,000 are now in use and they have been made a standard on practically all the

NO. 5, DRAW BAR

NO. 7, DRAW BAR

elevated roads in the United States. The company also has sizes especially adapted for mining cars to be used in mines. Everything is perfectly automatic and couples readily within 1-32 in. Every coupler is also machine fitted.



The W. T. Van Dorn Company has also done a large export trade and has furnished couplings for many of the leading street railways in Europe, couplers including roads in Glasgow, Bristol, Dublin and London, also to Australia and Japan.

Coal Conveyor of the Capital Traction Company

An extended description of the power station of the Capital Traction Company, of Washington, D. C., was published in the Street Railway Journal for January, 1898, but little was said at that time of the coal and ash handling system employed. The view, herewith, is of the ash tunnel, where ashes are taken from hoppers beneath the boiler furnaces, and from thence taken to ash storage tank. This tunnel is about 200 ft. in length, and each boiler has a feed chute to feed the ashes to conveyor. It is only necessary to open a gate in chute to allow the ashes to fall directly into the conveyor. As the latter acts exactly as a moving trough, no special feeding mechanism is required.

The coal, which is elevated to the bunkers above the boilers in the boiler house, is first raised from canal boats by a hoisting outfit, and run through a coal crusher. It is then fed to the conveyor in the tunnel, and thence elevated by the conveyor and carried to the bunkers, where it is distributed as desired.

The conveyor itself consists of a series of interlapping pans, in which are pivotally mounted buckets. The pans are bolted to the carrying axles, which are in turn connected by a steel cable, in place of the usual links employed in this class of machinery. In consequence of this arrangement the conveyor, as stated, is prac-

COAL CONVEYOR IN WASHINGTON.

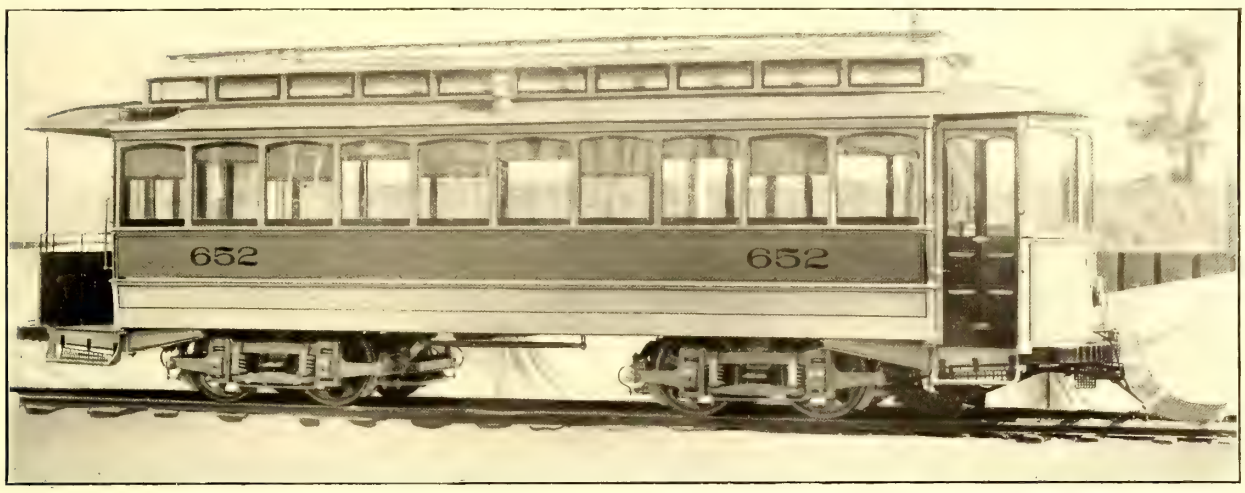
tically a moving trough in the part of the run where it receives the coal or ashes, and where the material is elevated or carried on a vertical or upper run the buckets swing freely in a horizontal position. The buckets are discharged of their contents by tripping mechanisms, in the usual manner. The whole outfit is very simple in construction.

A desirable feature of this machine is that where limited space only can be had on the lower run, that is, where the material is to be fed to it, a feed chute is not necessary, a simple opening in the floor being all that is needed, as the conveyor can run in a very small tunnel and quite close to the floor, thus occupying a very small space.

This machine as installed at the Capital Traction Company's plant has been in operation for a considerable length of time, and is giving excellent satisfaction. The whole coal and ash handling outfit for this plant was furnished and installed by the Steel Cable Engineering Company, of Boston and New York.

Welding Contract in Columbus

The Columbus Street Railway Company, of Columbus, Ohio, has increased its contract with the Milwaukee Rail Joint & Welding Company from 2000 joints to 5000 joints, at an increase in price corresponding to the advance in the prices of materials. About one-half of this work is on 7-in. and 8-in. T rail just laid.



This contract was secured by Henry L. Prather, manager of the Milwaukee Rail Joint & Welding Company's Cleveland office, and the work is under his immediate supervision. Mr. Prather has had four years' practical experience in electric welding, and is frequently called upon for expert experience on the subject of welding.

Dick, Kerr & Company, manufacturers and dealers in railway and tramway supplies, has been registered as a joint stock company, with a capital of £350,000. The company has acquired the English rights of much American machinery, including the Walker patents for motors and generators. The shops at Preston, Lancashire, are being equipped with American labor-saving devices at a cost of £50,000. The company has been awarded contracts for 900 trolley cars and equipments, which will be utilized on electric roads now in course of completion throughout Great Britain.

Closed Cars for Cleveland

The accompanying illustrations show two styles of closed cars built by the J. G. Brill Company for service in Cleveland, and which illustrate very clearly the tendency toward large units and high speeds.

The upper car, which was built for the Cleveland Electric Railway Company, has nominally a 28-ft. body with a 4-ft. vestibule in front and a 4-ft. 6-in. platform in the rear. It measures over the dashes 36 ft. 8 ins., and is 7 ft. 10 ins. wide over the posts. From the head of the rail to the underside of the sill is 31 ins. The steps are 16⅜ ins. from the ground, with 13-in. risers, and an 8-in. step leads from the platform to the floor of the car. The cars stand as near as possible 12 ft. 3 ins. from the head of the rail over the trolley board. They are mounted upon No. 27-F trucks, which have a 4-ft. wheel base with 33-in. wheels. The wheels have 2¼-in. tread with ⅝-in. flange and weigh 340 lbs. Each truck is fitted with a single Westinghouse No. 49 motor.

CLOSED CAR FOR CLEVELAND ELECTRIC RAILWAY COMPANY

The seats are longitudinal and upholstered in spring cane. The headlining is three-ply maple.

As will be seen, the car, in its general proportions, is not different from many others, but the first feature which is notably out of the common run is the fact that the car is built to run on a loop in one direction. Hence the vestibule at the forward end only. This vestibule is completely enclosed, having doors and step upon the right hand side. These doors close against the body of the car. Double folding doors give entrance to the body of the car from each end. The rear platform is also closed upon one side, having its entrance like that of the vestibule on the right hand side of the car looking forward. Platforms and vestibules thus arranged have an unusual amount of space. The dashers are high, measuring 40 ins. from the floor. Externally the car is somewhat peculiar on account of the steam road hoods to the platforms, and the unusual elevation of the trolley board above the roof. At first sight the steam road hood seems inappropriate to a car of this class, but it must be remembered that the speed is unusually high, and therefore the roof is desirable. The general objection to the steam roof has been that if injured in an accident a considerable amount of damage is done to the car itself, because the framing extends through. While the car framing is somewhat strengthened by this construction, at least where there is a vestibule, the amount of damage done by trivial accidents is often very great. In this case, however, the vestibule and platform hoods are distinct from the framing of the car, the hood can be destroyed without necessarily injuring the roof frame. On the rear hood numerous strips of ash are placed, covering a considerable space. This is put on for the purpose of protecting the hood against the rebound of the trolley pole when it comes off the wire. It has been found with the extremely high speeds used on the Cleveland roads that the trolley pole whips backward and frequently destroys the hood after leaving the trolley wire. Such a contingency could hardly have been foreseen from experience which was confined to 12 miles or 15 miles per hour, but when cars, on country lines, often run at a rate of 53 miles or 60 miles an hour, conditions are entirely altered.

CLOSED CAR FOR CLEVELAND CITY RAILWAY COMPANY

The insides of the cars are very neatly finished. The backs of the seats are of cherry with the windows drop and have spring curtains. The cars, although quite simple in their design, are built with the greatest care, and in spite of their great length every rail was put in without splicing. The posts are of ash throughout. The end sub-sills are of ash and the crossings of yellow pine. Steel reinforcements are used frequently throughout the framing. The crown pieces are of oak and all the ends of white oak. They are reinforced by angle iron. The band irons covering the joints of the belt rail are in each case continuous pieces from door to door. All the joints at the corners

of the car were carefully covered either with special pieces of stamped steel or by suitable bands and crossings bedded in white lead. There are the usual inside truss rods with 7/8-in. round ends fastened upon the posts and securely anchored at the end sills. There are also inside belts running direct from corner post to corner post. The details of construction have been very carefully worked out, and wherever an improvement has been made it has been introduced. For example, the entire edge of the rear canopy or hood is bound with oval iron to prevent the trolley rope from wearing the canvas. The canopies are so designed that they cannot come in contact with a trailer when rounding a curve of 30 ft. radius. Under the vestibule are fitted Littell scrapers of the latest design, arranged to be hung up when not in use. On the vestibule is an opening or lantern just below the level of the dasher rail, the front of which is closed by a perforated metal sign showing the destination of the cars in transparent letters. Guard rails are reinforced on top with 3-16-in. steel plate laid in white lead. The floor mats are of straight grained hard maple strips. These strips are screwed to three-ply rubber belting with brass screws and the belting let into the underside of the strip flush. They run crosswise of the car and four mats are required for each car. The inside trim of the car is of solid bronze. In putting up the hand pole brackets a slight refinement is introduced, which is of considerable value to the passengers. It is an extension of the bracket toward the center of the car 6 ins. from the face of the inside ventilators. This brings the straps further out, making it much pleasanter for those who are seated and much easier for the persons who stand.

Each car is equipped with two sand boxes at the forward end. They are arranged to work simultaneously by a pedal on the front platform. The delivery pipe is made of tight coil spring wire 1/4 in. in diameter. This gives a pipe opening of 2 1/2 ins. The cars are heated by full length stoves placed on the same side of the car as the steps. The stove box is 18 ins. square at the bottom and 36 ins. high. The spring seat has a section cut from it at the center, which is removed when the stove is put in place. There are fifteen lights on each car, twelve inside, arranged four on three electroliers, one light on the rear platform and one in the lantern in the signal box in the front vestibule. There is also one for the headlight on the top of the front hood. There are eight small trap doors in each car, four at each end.

In the car there are ten ventilators, every other one hung at its forward edge so as to open outward. There are movable panels over the head of the door to give access to the door moving mechanism. At each side of the door the swing sash are fitted with bronze stiles. The doors themselves open 36 ins. The curtains are very carefully fitted as well as all the door furniture. Hand rails are of cherry and have sixteen padded straps of light leather on each rod. A part of the cars are furnished with Sterling brakes. In all cases the brake power is arranged to give the motormen great leverage in applying the brakes.

The lower view shows a car built by the J. G. Brill Company for the Cleveland City Railway. The body is 30 ft. long, 7 ft. 10 ins. wide at the belt rails and 38 ft. 6 ins. over the dashers. There is a platform 4 ft. 6 ins. in length at the rear end and a circular vestibule at the front end 4 ft. in length. It is sheathed with steel and has a folding door at the right hand side. Like most of the cars intended for Cleveland service there are openings on the right hand side only, the cars running continually in one direction around loops. A still further departure from common practice is found in the location of the doors at the corners of the cars next the platform opening. This arrangement necessitates the cutting of the longitudinal seats away at each end to give space for entrance. This, of course, diminishes the seating capacity by that amount. The seats themselves are spring upholstered, covered with plush carpeting. There are eleven windows on each side, and in the ventilating sash three at each end open sidewise. The stove is placed on the same side of the car as the doors. Externally the car is somewhat unusual in appearance. It has apparently a steam road hood. This, however, is not framed as a part of the monitor deck of the car, but is put in separately as a part of the hood. The cars are fitted with No. 27-F trucks and have four 12-A No. 30 nose suspension W. P. Westinghouse motors. This equipment will enable these cars to make the highest speed permitted in either the city or the country.

In these cars the trolley board is placed over the center of the rear truck. The bumpers are the Brill angle iron pattern. Two sand boxes are placed in the front end of the car. There are two Dedenda gongs. Bronze trimmings are used throughout. The posts are all fitted with push buttons and electric bell connections. The advantages of cars which run in one direction only are numerous. Notably there is an absence of gates and an increase in the space available on the platform. Since the entrance is from one side of the platform only, passengers, when the car is crowded, enter and leave with greater comfort and more quickly than in the ordinary style. The steps are much more easily kept clear and a greater degree of safety results.

Controlling Motors by Pneumatic Means

The growing interest in methods of controlling several motor cars from one point is shown by the adoption of this system upon several elevated railways in this country, and by the large number of patents for different methods of accomplishing this result, which the Government has granted recently. In this connection it is interesting to note that one of the early and basic patents for synchronously operating several motor controllers by pneumatic power was granted to Sidney H. Short, the well known inventor, and at that time connected with the Walker Company. This patent, No. 599,807, was issued March 1, 1898, and contains forty claims, of which the first and second are as follows:

(1) In a system of controlling motors in a train of cars, a controller for each car, fluid-pressure mechanism for simultaneously actuating said car controllers, and means mounted on each car of the train for controlling said fluid-pressure mechanism.

(2) In a train of several cars, motors mounted on one or more of the cars of the train, a motor-controller mounted on each motor-car, a fluid-pressure mechanism for actuating all of the controllers throughout the train, and means located on each car of the train for controlling said fluid-pressure mechanism.

Supplies in Chicago

The W. R. Garton Company, of Chicago, reports doing an elegant business. This company handles all kinds of electrical and mechanical supplies for railway, light, power and transmission purposes, and represents some of the best-known manufacturers in the country; thus, it is agent for and has territorial arrangements with the Electric Railway Equipment Company of Cincinnati, Ohio, manufacturers of all kinds of railway supplies, line material, tubular iron and steel poles and brackets, etc.; the Billings & Spencer Company, of Hartford, Conn., drop forgings, B. and S. commutator bars, Kelsey patent brake handle, etc.; the General Equipment Company, Camden, N. J., automatic circuit breakers; Kingston Electrical Instrument Company, Philadelphia, voltmeters, ammeters, etc.; Massachusetts Chemical Company, Boston, Mass., insulating paints, tapes, cloths, paper, etc.; the Multiplex Reflector Company, Cleveland, Ohio, all kinds of reflectors and headlights; the Eureka Tempered Copper Works, North East, Pa., the McLaughlin rail-bond; the Graphite Lubricating Company, Bound Brook, N. J., genuine Bound Brook trolley bushings; Lea Manufacturing Company, Elwood, Md., all kinds of enclosed arc lamps; Pittsburgh Steel Hollowware Company, Pittsburgh, Pa., pressed steel gongs; A. O. Schoonmaker, New York, all forms of amber and India mica; E. F. DeWitt & Company, Lansingburg, N. Y., common sense sand box; Miller-Knoblock Company, South Bend, Ind., assembled commutators, refilled commutators, armatures rewound, etc. The company also carries in stock insulating paints, "Columbia" tapes, "America" incandescent lamps, Garton lightning arresters, knife switches, etc., and makes a specialty of fine switchboard work and supplies. It also sells the National Carbon Company's carbon motor brushes, and enclosed arc lamp carbons, and Van Dorn & Dalton's gears and pinions and track scrapers, and is doing a nice business in these lines.

The Indianapolis Street Railway Company has closed contracts with the North American Railway Construction Company, of Chicago, for the reconstruction of six of its lines, and for an extension to Riverside Park, the work to be done by Jan. 1. This contract, with what the company has already expended in rebuilding lines, will aggregate $1,000,000.

Large Wire Producers

The consolidation of wire interests has modified trade conditions in the electrical field to a less extent than would seem possible at first sight. This has been partly due to the fact that one of the largest plants which manufactures copper wire and cables, i. e., the John A. Roebling's Sons Company, has remained independent. This company is said to have the largest individual plant in existence, both for producing electrical conductors and wire rope. The name of the illustrious engineer who built the Brooklyn Bridge, and was the author of many engineering achievements, has been a stamp for excellence on all of the products of the mills of the company, which is fortunate enough to be under the guidance of the present generation of Roeblings. It may be of interest to indicate briefly the extent of the works and the durability of products of the Roebling Company.

The main plant is at Trenton, N. J., situated conveniently for railroad and canal transportation. It covers upward of 25 acres of ground, and it possesses a large rolling mill, with a capacity of about 300 tons or rods a day, where a large variety of material is turned out. There are two large wire mills for producing iron, steel and copper wire, with a third in process of construction, which will be enormous. This mill is to cover 325 ft. x 60 ft., and will be five stories high, equipped with the latest and best machinery. Cleaning and annealing houses, galvanizing and tinning mills, machine and blacksmith shops complete, the plant will be devoted simply to the manufacture of wire.

It will serve the purposes of this sketch only to mention the wire rope mills, which are the most extensive of their kind, and pass to the section devoted to the production of electrical conductors. Four or more large buildings are equipped with the machinery necessary to turn out this variety of material. Arbitrarily electrical conductors may be divided into four classes: bare; insulated with vegetable fibre, dry or impregnated with various compounds; insulated with rubber, and wires which are mechanically protected by an outside metallic covering. The Roebling Company manufactures wires and cables of each of the above classes.

Under the head of bare conductors are various subdivisions, such as trolley wire, galvanized telegraph and telephone wire, hard drawn telephone wire, soft tinned copper wire and various stranded conductors and cables, for the production of which this plant is well equipped. The second class includes, among others, magnet wire, round, square and of various other shapes, which requires the nicest discrimination in choice of material and the most delicate manipulation. A variation in diameter of magnet wire of more than 1-2000 in. is not permitted in some sizes. This class also includes weatherproof conductors with solid or stranded conductors of iron or copper, office and annunciator wires, etc., etc. The Roeblings have equipped a very large number of trolley lines and electric light plants with weatherproof wire, and have a deserved reputation for excellent work in this department. The Roebling rubber mill has been in existence for only about one year, but its success was instant, and the popularity of its products demanded a speedy doubling of the plant. All kinds of conductors are made, which are included in the third class of conduction material. Under the fourth heading are comprised the most important electrical conductors of to-day, these are the so-called lead incased cables, used for telephone, telegraph, light and power purposes. Cables prepared under either of the former heads of insulated conductors, require a mechanical protection when introduced into subways and conduits.

The tendency in thickly populated centers is decidedly toward placing electrical conductors under ground for obvious reasons. The best form of mechanical protection, according to American practice, is a lead pipe, either alloyed with or coated with tin. This pipe is formed about the conductor, and when the lengths of cable are drawn into the conduits and connected up, it serves as a complete sheath, excluding moisture and preventing mechanical injury to the conductor.

The Roebling plant is equipped with machinery enabling it to turn out the best lead-encased cables of all kinds for telephone, light and power plants. Rubber and also fibre are used for insulation, according to requirements. A recent large order for New York companies of some 400,000 ft. of cable is now being filled, the conductor being rather novel. The order calls for a three-conductor cable, each conductor with an area of a 0000 stranded wire, insulated with rubber, and encased in a lead pipe, forming a complete cable about 2¾ ins. in diameter.

This company equipped the first under-running trolley system successfully operated in the United States, and claims to have supplied probably more than two-thirds of all the conductors used for this purpose. A carefully trained corps of skilled workmen installs all of the lead encased cables, and competently attends to the problems which are met in this class of work.

New Power Brake Factory

Judging from the amount of business done by the Christensen Engineering Company during the past twelve months, together with the large number of orders for immediate delivery which the company has on hand at present, it would appear that the question of power brakes for electric cars was being answered in a most emphatic and satisfactory manner. This company, after having twice within a year doubled its capacity, now finds that the demand for its air brakes is so large that another increase of 100 per cent will be entirely inadequate. Believing that the very satisfactory results obtained by all the roads using its devices, has thoroughly demonstrated that the apparatus is now reduced to a condition of efficiency and durability which insures its success, and that the amount of business already consummated, together with the large amount on hand and in sight, fully warrants the investment of sufficient capital in special machinery to insure not only prompt deliveries, but the manufacture of goods at a cost which will permit their sale at the lowest possible price, the company has purchased a factory site of 7 acres, conveniently located as to railroad facilities. On this site it is erecting a modern plant, consisting of foundry and machine shops which will give the company sufficient capacity to insure the filling of orders promptly.

The plans for the new shop have been drawn with great care and all the latest conveniences known to the trade will be incorporated. Compressed air will be used in the many capacities for which it has proven the most suitable power, and machine tools will be run by electric motors arranged in small units for convenience.

The works are so arranged that there is ample space between the buildings, giving plenty of light, and the spaces not occupied, will be devoted to well kept lawns.

The power house will be located centrally, so that the electric transmission to the motors located in various parts of the works will be effected with the least possible amount of loss.

The boiler room is immediately adjoining a railroad track and is slightly lower than the latter so that coal is easily unloaded.

The power house will, besides the boilers, contain direct-connected generators in units of 100 h.p., and various dynamos for giving voltages of 80, 110, 220, 250, 450, 550, 650, 750 and 1000 volts for testing purposes as well as power.

The foundry will be located near the power house and the coke bins and a store house for pig iron will be immediately alongside the track, within easy reach of the cupolas. The foundry will be fitted up with the latest improved machinery, having electric traveling cranes and compressed air cranes for the lighter work. The method of molding will be in accordance with the latest improved practice, compressed air being used for tamping, and wherever practical to use it. This foundry building is connected with the main buildings by means of compressed air cranes with tracks arranged in such a way that the product can be transferred readily. The machinery in the foundry will be operated by electric motors throughout, in fact, no steam will be used anywhere in the plant, except in the power house.

The main machine shop will be arranged with electric traveling cranes to handle the heavier work. The lighter work will be handled by compressed air cranes, arranged to cover practically the whole area occupied by machine tools, in which articles weighing over 50 lbs. are being finished. The machines will be so arranged that when the parts are finished, they will be near the department where the complete equipments are assembled. Immediately adjoining this department is the testing room in which also are arranged cranes of various capacities for handling the machines, and after testing, the equipments are either shipped or deposited in the warehouse, which is arranged with a railroad

track immediately in its center. The warehouse is likewise fitted up with cranes for conveniently handling the goods and is also provided with wood-working machinery for making packing boxes, both for domestic and foreign shipment.

Stored Air for Braking Cars

No department of railway practice has in recent years received closer attention and more minute study than that of brakes. The hand brake has been in use ever since the first street railway was built, and up to about 1860, was in exclusive use on steam roads. The main defect in the ordinary hand brake is its narrow limits of power, which is confined to the strength of the motorman. When the size, weight and speed of many of the modern electric cars are considered, it is not surprising that the ordinary hand brake is not considered adequate by many managers and that increased attention should be given to air and other power brakes.

Since the convention at Boston a year ago, a new air brake for electric cars has made its appearance, that manufactured by the G. P. Magann Air Brake Company, of Detroit. Coming into the field in January of this year with the recommendation from one twelve-car road entirely equipped and in operation for one year previous, the company has taken orders for entirely equipping six interurban roads, aggregating forty-two cars. These roads are as follows:

	Brake Equipments
Kansas City & Leavenworth Railway	10
Cleveland & Eastern Railway	8
Mahoning Valley Railway	3
Sandusky & Interurban Railway	3
Detroit, Rochester, Romeo & Lake Orien	6
Detroit & Northwestern Railway	12

A few of the more important advantages claimed for this brake are: (1) No complicated machinery is used, no air pumps, pump controllers, electric motors or triple valves; (2) a constant supply of air, at full working pressure, is always ready for any number of quick applications in an emergency; (3) the brakes are released positively and instantaneously; (4) it is absolutely noiseless in operation; (5) leakage of air is completely done away with; (6) there is no possibility of break-down, except in collision or derailment; (7) less than 1 lb. of air is required to the stop; (8) low first cost; (9) the cost of maintenance is practically nothing.

The Magann system differs vitally from all other present methods of air brake application. Stored air is used, confined in reservoirs fixed to the car. These are quickly charged from a stationary air compressor at the power station or any point on the line, at a pressure sufficient to allow the car to make an average of 300 stops or a maximum of 500 stops. There is very little mechanism on the car, and the moving parts of the air brake system, such as air compressor, regulator and automatic, are removed to the station, where they are under the care of the power house engineer. This reduces largely the amount of apparatus required, greatly simplifying the whole system and reduces the operating expense to a minimum.

Now as to the practical working of the brake. The risk incurred in the reversing of motors, when necessity demands a quick stop, is entirely obviated. The time required in braking is much less than is generally required to reverse a motor. It is also claimed that with this system "skidded" wheels never occur, owing to the "air cushioning" in the two cylinders, the peculiar construction of which prevents the possibility of undue pressure at the shoe. Furthermore, the brakes never become "jammed." The efficiency of the Magann air brake, under all conditions of weather, etc., has also been thoroughly demonstrated.

The system will be on exhibition at Tattersall's during the convention, where a working exhibit will be shown.

Chain Grates

The Green traveling link grate, though ordinarily designated as a chain grate and in general appearance similar to other chain grates, actually differs in many features from other automatic stokers of this kind. One of the distinctive features is that the clips or links forming the grate are so designed that they can be readily removed from or replaced in the chain without removing the joining bars or any of the principal parts. In fact, it is almost possible to take out and replace a clip without stopping the grate. Each clip is about a foot long and on the underside of the ends are oval openings which permit the links to be slipped over the bars, after which the bars are turned so as to bring their largest diameter across the opening in the link so that the latter cannot drop off. The joining bars, which as will be seen, are also oval in section, are held in position by means of binders.

Another feature of the grate is that it is provided with roller bearings on which the chain rides, giving a positive and easy movement without the use of lubricants. These bearings are housed in so that they are entirely protected from dust and ashes. The chain is moved by means of sprocket wheels which engage with lugs on a row of specially designed links. The entire grate is also mounted on a carriage, having wheels which run on a track specially provided for it so that the grate can be entirely withdrawn from the furnace without interfering with the boiler setting. The coal is fed in through a hopper.

Recent tests made on one of these grates in the large power plant of the West Chicago Street Railway Company, at Western Avenue, using Indiana shell bark screenings containing 10,300 B. T. U. showed that a grate under a 400-h.p. boiler while developing 523 h.p. gave an efficiency of 75.3 per cent. The maximum h.p. developed during a capacity run on the same boiler showed over 730 h.p. developed.

These grates are manufactured and sold by the Green Engineering Company, of Chicago. During the last three years almost 40,000-h.p. "Green traveling link grates" have been sold. Among the larger orders were the West Chicago Street Railway Company, the Milwaukee Electric Railway & Light Company, Metropolitan Street Railway Company, Kansas City; United Railways Company, St. Louis; Armour Packing Company, Swift & Company, Cincinnati Edison Electric Light Company, and a good many others. This company not only manufactures this grate, but is also contractor for complete installation of power plants for either electric lighting purposes or street railway plants. The officers of the company are W. M. Green, president; John R. Gent, vice-president; P. Albert Poppenhusen, treasurer, and Herman A. Poppenhusen, secretary. All of these gentlemen are well known and have had practical experience in the installation of steam plants, having been connected with some of the leading engine and boiler manufacturers of the country.

A Large British Supply House

One of the long established and best known British firms which has engaged in the manufacture and sale of electrical apparatus and instruments for tramway work is Elliott Bros., of London. This firm was established in 1800, and has taken the highest awards for apparatus exhibited at every exposition at which it has entered as a competitor.

One line of busines in which Elliott Bros. have enjoyed an excellent trade, has been in the sale of Weston electrical instruments, for which they are agents. Owing to the requirements made by the British Board of Trade electrical department, with a view to preventing disturbance on telephone and telegraph lines, electrolytic action on pipes, etc., certain records have to be kept by the electric railway companies to show the amount of current returning to the station through the earth, and not along the uninsulated return or rail or any return feeder. Soon after the passing of this regulation Elliott Bros. had designed a set of instruments to do this work and make the graphical records necessary. This work was followed by making and placing on the market a complete switchboard panel to carry out all the tests required by the electrical department of the Board of Trade. This line of apparatus has been most cordially received by the trade. The firm is also intending to increase its manufacturing facilities to enable it to undertake a more extended position in electric traction work, which it is now prevented from doing through lack of space. In addition, of course, the firm is supplying a great many traction stations with many other accessories, such as speed indicators, steam engine indicators, etc., which form a regular part of its manufactures.

In connection with three-phase transmissions of power for electric traction or whatever may be required, the company is also planning to manufacture recording wattmeters for such circuits.

Some Recent Electrical Work in England

Laing, Wharton & Down, Ltd., have recently done a considerable amount of electrical work in different parts of Great Britain. In the line of electrical traction the firm has completed and turned over to the Glasgow Corporation a pair of generators and engines of 900 h.p., to be used in their combined station, has completed a small electric railway in the West Riding of Yorkshire for private use, and has delivered to the Corporations of Glasgow, Manchester, Leeds and Hull large numbers of Brill trucks—those for Hull being fitted with roller bearings. It has also recently filled orders from the Bristol Tramways Company for both trucks and cars, and from the Hull Corporation Tramways for cars. The firm has also practically completed the delivery of several large switchboards for the Glasgow Corporation of various sizes to suit the large generators, the largest one being 1800 amps. 600 volts; has completed the extension of the Halifax Corporation Tramways switchboard, and has supplied a large switchboard to the Barking Urban District Council, the West Riding County Council, and the County Council of Hertfordshire. In connection with traction may be classed the firm's extensive business in Vril electric launches, which is constantly on the increase. The problems in connection with electric launches are of as much interest as those in railway work, but, of course, do not involve such large powers. In connection with these launches and also with general industrial motor work, the firm has manufactured a large quantity of Callow-Eck controllers, which have again been improved recently in the way of simplification and greater efficiency.

For tramway track work the firm has received large orders for rail saws, drills and Pearson jacks, as well as for Okonite wires and Okonite and Manson tapes. The wonderful durability of Okonite insulation, and its resistance to the attacks of oil, acids and alkalies have rendered it particularly popular for tramway service in Great Britain.

Laing, Wharton & Down also do a large busines in the allied business of electrical work. In connection with lighting the firm has executed a large number of contracts, among which may be mentioned seven churches, three hospitals, four theaters, and the same number of post offices, as well as for a large number of warehouses, mills, banks, offices and private dwelling houses. Another specialty of the firm is the erection of electric advertising signs. Such signs have been installed by them in London, Nottingham and Sheffield, each containing over a thousand lamps, and capable of advertising without any change except on the card, and producing in a few minutes any desired advertisement. A similar sign will shortly be erected in New York, and possibly also in Paris.

The firm also manufactures a large quantity of high tension apparatus, as well as switchboards, switches and various other electric appliances for trade consumers, including theater battens and other special theater devices. They have taken up the handling of three-phase apparatus in Great Britain, and anticipate to have a fair demand in connection with power installations and isolated factories.

An Electric Snow Sweeper Train

The McGuire Manufacturing Company, of Chicago, has decided for the month of October, a rather novel method of advertising. It has arranged for a special train of forty-three platform cars, each car carrying one of its snow sweepers, decorated with banners and mottoes. The train will leave Chicago during the convention, after being exhibited for one day on a side track at a point nearest the Convention Hall. It will then proceed on its way to New York via Washington, delivering sweepers en route and stopping at places where the company thinks sweepers are likely to be sold, where a representative of the company will invite the railway officials of the place to review the train. When the train reaches Washington, it will be reduced to seventeen cars. Leaving ten there for the Columbia Railway, it will proceed to New York, dropping one at Chester, Pa., and completing the trip by delivering six at New York City for the Metropolitan Street Railway Company. This will undoubtedly be the largest train of this sort of freight that has ever been made up in any country. Sixty sweepers are now being constructed in the shops of the McGuire Company for shipment in the month of October. To accomplish this and at the same time take care of the large truck business of the company, about 350 men are working night and day. It is a singular fact that they have sold sweepers as far west as Portland, Ore., south to Augusta, Ga., and east to New York City.

Forced Draft

The argument is sometimes advanced against the use of forced draft instead of induced draft, that it burns out the grates, seriously injures the boiler, and blows gas and smoke from the fire doors. The basis of this opinion lies in the experience of some engineers with plants equipped with fans operated at far above the proper speed. This is usually the result of installing, through ignorance, a fan too small for the work, and then forcing it above its normal speed in order to secure the desired air volume. As a consequence, instead of creating an ash pit pressure of ¾ in. to 1¼ ins., which is all that is ordinarily required, the presure is forced up to even 5 ins. or 10 ins., with the attending objectionable results.

In a recent instance the engineer complained of gas discharged from the fire doors with incidental effects, and condemned forced draft in toto, although he was favorably disposed toward induced mechanical draft. Investigation showed that the fan was being operated at about 12 ins. water pressure, which at once accounted for all the trouble.

When forced draft is used, the air as it passes from the ash pits to the combustion chamber is greatly reduced in pressure, owing to the resistance of the grates and the fuel. Coincidently, the stack, even if a short one, tends to produce a partial vacuum in the furnace. As a result it is practically impossible to create under proper conditions more than a slight excess of pressure in the combustion chamber, and this should not be enough to force the gases out at the fire doors.

Electric Tramway Apparatus for Sheffield, England

The following is a list of the machinery and apparatus purchased by the Sheffield Corporation for their tramways, and supplied by the British Thomson-Houston Company, Limited.

Boilers.—Three boilers of marine type each 10 ft. diameter x 10 ft. long, made by John Brown & Company, Limited, and fitted with Ellis & Eaves induced draught system. They are fitted with Purve's ribbed furnaces and "Serve" ribbed tubes. Each boiler will evaporate 8000 lbs. of water per hour, the working pressure being 160 lbs. per sq. in. Two fans, each worked by an inverted vertical steam engine, are furnished for the three boilers.

Boiler Feed Pumps.—There are two "Manchester" vertical duplex type pumps made by Frank Pearn & Company, Limited, of the following dimensions: Diameter of steam cylinders, 5½ ins.; diameter of rams, 3½ ins.; stroke, 5 ins.

Surface Condenser.—One Wheeler Admiralty Surface Condenser containing 1900 sq. ft. surface with combined air and circulating pumps as follows: One 14-in. steam cylinder, one 16-in. water cylinder, one 16-in. air cylinder, all 16-in. stroke cylinders.

Feed Water Heater.—There is one horizontal Wheeler feed water heater, located between the feed pumps and the boilers, for working in conjunction with the exhaust steam from the auxiliary plant.

Feed Water Filter.—One pair Edmiston feed water filters arranged on the twin system, so that the feed water can filter through one, or all, or, in the event of their becoming out of use, to feed through an independent by-pass, thus making feed line entirely independent of the filters.

Piping.—The steam and exhaust piping is made of lapweld steel pipe with flanges screwed on at the ends. All circulating water pipes are also of lapwelded steel pipe. The fittings in all cases being of best quality cast iron. The valves are of the straight way or gate type made by Messrs. Hopkinson, of Huddersfield; the pipe all having been furnished by the Best Fox Manufacturing Company, of Philadelphia.

Engines.—Three Allis horizontal tandem compound engines: Cylinders, 12-in. x 22-in. x 30-in. stroke; r.p.m., 135; initial steam, 150 lbs. per sq. in.

Overhead Traveling Crane.—One 20-ton overhead hand traveling crane, made by Joseph Booth & Bros., of Rodley.

Generators.—Three British Thomson-Houston generators, multipolar type, having six poles, and a rated capacity of 225 kw., designed for a working potential of 500 volts when running at a speed of 135 r.p.m. These machines are compound wound so as to maintain the voltage constant within 2 per cent for all loads up to rated full load, the speed being maintained constant, and the position of the brushes remaining fixed. These generators are direct connected to the engines mentioned above.

Switchboard.—This consists of three generator panels, one feeder panel, one Board of Trade panel. The generator and feeder panels carry automatic circuit breakers of the magnetic blow-out type, Weston illuminated dial ammeters, and all necessary switches, etc., for the complete control of the generators and feeder circuits. There are also two illuminated dial Weston voltmeters supported on a bracket at one side of the board in such a position that it can bee seen by the attendant when manipulating the apparatus at any part of the board. The Board of Trade panel is of the British Thomson-Houston standard type, containing all the necessary instruments for making the records and tests as called for by the various Board of Trade regulations.

Cables.—Are of the Callander well known type, insulated with jute saturated with fine bitumen, lead covered, taped and braided with a specified insulation resistance of not less than 700 megohms per statute mile after twenty-four hours immersion in water at 60 degs. F. When laid and jointed the cable should withstand an application for one hour of a potential of 1000 volts. In addition to the feeder cables, Messrs. Callander have supplied the cables connecting the trolley wire with various feeder pillars. The return feeder cable and the three-core test cable, aggregating over 13 miles of cable.

Overhead Line Construction.—The poles and brackets being supplied by J. Spencer, of Wednesbury; the suspensions, etc., are of the standard British Thomson-Houston type. The feeder pillars are of the standard British Thomson-Houston type, and in accordance with Board of Trade requirements, and are so placed as to divide the line into quarter-mile sections.

Cars.—Twenty-five motor cars, complete, were supplied; the car bodies being of the top-seat type, built by Messrs. Milnes & Company. The cars are capable of seating twenty-two passengers inside and twenty-nine out. They measure, overall, 27 ft. 6 ins., and have a width of 7 ft. The height inside at center from floor of under side of roof is 6 ft. 6 ins., and the approximate weight is 65 cwt.

The trucks are the Peckham extra long cantilever extension type, supplied to the British Thomson-Houston Company by R. W. Blackwell & Company. The electrical equipment of each car consists of two G. E.-52 railway motors, two series parallel controllers of the magnetic brake type and the electric brake equipment, the shoes and discs being mounted on the truck frame and axles respectively.

The above apparatus is that covered by the original contract between the British Thomson-Houston Company and the Sheffield Corporation, since the signing of which the following additional orders have been received by the British Thomson-Houston Company for extension: Two eight-pole, 500-kw., 90 r.p.m. generators, similar to the 225 kw. described above; two generator panels and one feeder panel, twenty-five double motor equipments with magnetic brakes, and thirteen double deck cars and trucks, also overhead line material, cables, etc., for the Walkley and other extensions; all of similar kind to that described above for the original contract. The Sheffield corporation also placed with the British Thomson-Houston Company, Ltd., last month, an order for thirty double motor equipments similar to those already supplied.

Personal

MR. W. B. ROMMEL, of London, who is in this country for several weeks, is now at Niagara Falls enjoying a brief vacation.

MR. PATRICK McARDLE has been appointed assistant superintendent of the Easton, Palmer & Bethlehem Street Railway, of Easton.

MR. EDWARD A. BROWN has resigned as master mechanic of the Greenfield & Turner's Falls Street Railway, to accept a position at Boston.

MR. G. F. GREENWOOD, manager of the Havana Electric Railroad Company, was in Pittsburgh last month, contracting for general good time had.

MR. D. LILLIBRIDGE has resigned the position of advertising manager of C. W. Hunt Company, and is spending a vacation among the Thousand Islands.

MR. H. S. COOPER, formerly superintendent of the Schenectady Railway Company, has been appointed general manager of the Ithaca Street Railway Company.

MR. WM. ATKINS, secretary and treasurer of the Tuscarawas Railroad Company, of New Philadelphia, Ohio, has recently been appointed general manager of that company.

MR. ALEXANDER E. ORR, president of the New York Rapid Transit Commission, has just returned from a trip to Great Britain. Mr. Orr's trip was purely for pleasure.

PROF. WILLIAM S. ALDRICH, formerly of the University of West Virginia, has accepted the position of professor of electrical engineering in the University of Illinois at Urbana.

MR. EDWARD D. PAGE has been elected president of the South Orange & Maplewood Traction Company, of South Orange, N. J., to succeed Mr. Frank Brewer, who recently resigned.

MR. FRANK BREWER has resigned as president of the South Orange & Maplewood Traction Company, of South Orange, N. J., with which he has been connected since the road was placed in operation in 1895.

MR. C. W. FOOTE has resigned the general managership of the Zanesville Railway & Electric Company, to accept a position with the Cincinnati & Miami Valley Traction Company, of Cincinnati.

MR. EUGENE A. WISE, train master of the Manhattan Railway Company, of New York, has resigned his position after twenty-one years of service in the company. Mr. Wise was a member of the Municipal Council of New York.

MR. P. H. GADSDEN, of Charleston, S. C., formerly attorney for the Charleston Consolidated Railway, Gas & Electric Company, has been elected vice-president and acting president of that company, vice Dr. J. S. Lawrence, deceased.

MR. E. W. POOLE, who for the past 3½ years has been cashier at the main office of the Waterbury Traction Company and Connecticut Lighting & Power Company, has been transferred to the general office of the company, at New York.

MR. HENRY SCHNITGER, former lessee and superintendent of the Davenport & Rock Island Railway Company, now the Tri City Railway Company, of Davenport, died in Oklahoma City, Sept. 16. He is survived by a wife and four children.

MR. BURT VAN HORN, general manager of the International Traction Company's lines in Buffalo and Niagara Falls, is to spend next winter in Europe, on account of Mrs. Van Horn's health, but Mr. Van Horn will be again at his post in the spring.

MR. S. POTIS, who designed and built a number of the principal electric railway power stations of Chicago, has recently accepted the position of chief engineer of the Illinois Telephone Construction Company, with headquarters in the Rookery Building, Chicago.

MR. H. R. FEHR, superintendent of the Easton, Palmer & Bethlehem Street Railway Company and former city engineer, gave a banquet at the American House, Bethlehem, recently, to the members of the Highway Department, city officials and representatives of the press.

MR. PAUL K. BRAWD, chief engineer of the Russian Electric Company Union, of St. Petersburg, Russia, sailed Sept. 2 for France. Mr. Brawd is to return to this country in December next to arrange with manufacturers for the representation of their interests in Russia during 1900.

MR. JOSEPH S. MINARY, the retiring general manager of the Southern Electric Railway, of St. Louis, was pleasantly remembered by his former employees, who presented him with a handsome chain and locket. Mr. Minary has been transferred to the northern division of the United Railways Company.

MR. A. W. LYNN, who, since 1885, has been identified with Milwaukee street railway interests, has resigned his position as superintendent of construction and maintenance of the Milwaukee Electric Railway & Light Company, and will become general manager of the Milwaukee Railjoint & Welding Company.

MR. FRANK WEBSTER, of the construction department of the Market Street Railway Company, of San Francisco, was tendered a banquet Sept. 3 by a number of his friends, the occasion being his recent attainment of the thirty-second degree in the A. and A. S. rite of Masonry. During the evening Mr. Webster was the recipient of a very handsome typical emblem.

SIG. GUIDO SEMENZA, chief electrical engineer of the Milan (Italy) Edison Company, arrived on the steamship "City of Rome" from Glasgow, on Sept. 4, and will make a careful study of electric lighting and tramway work in this country during the next few weeks, going west as far as St. Louis, Chicago and Minneapolis, and visiting the principal cities en route.

MR. JOHN H. SESSIONS, president of the Sessions Foundry Company, makers of the "Composite" brake shoe, died at his home at Bristol, Conn., Sept. 10. Mr. Sessions was also president of the Bristol National Bank and the Bristol Water Company, and was a director of the Bristol & Plainville Tramway Company. He is survived by a widow, two sons and a daughter.

COL. N. H. HEFT, president, secretary and chief electrician of the Meriden Electric Railroad Company, and president and purchasing agent of the Stamford Street Railroad Company, was injured a few days ago while alighting from a street car. Mr. Heft wrenched his knee and was compelled to take to his bed for a few days, but is now able to be about, and no serious results are anticipated.

MR. A. R. MOORE, president of the Escanaba Electric Street Railway Company, tendered a number of his friends a trolley ride Aug. 25. The party journeyed on one of the company's large interurban cars to Flat Rock, where supper was enjoyed and a general good time had.

MR. JOHN E. SANFORD, of the Mass. State Board of Railroad Commissioners, is said to have resigned. Mr. Sanford, who has been identified with the board since his appointment by Governor Russell, refuses either to confirm or deny the report. He has been in poor health for several months, and has been compelled to confide the greater part of the detail work of the commission to his associates, Messrs. Bishop and Goodwin.

MR. H. A. TYLER, president of the Trolley Club, composed of employees of the New London Street Railway Company, has resigned his position with the company and also as president of the club to enlist in Forty-sixth Regiment now being organized for service in the Philippines. Mr. Tyler was held in great esteem by his associates and was, upon his departure, presented with a handsome gold mounted briar wood pipe as a token of remembrance.

MR. H. B. WESTCOTT, general manager of the Cortland & Homer Traction Company, of Cortland, N. Y., has entered the theatrical field, and, together with Mr. C. W. Burrill, has incorporated the Burrill Comedy Company, of Cortland. The plans of the company are not yet fully matured, but it is stated that it is the purpose to organize a comedy troupe and travel during the coming theatrical season. Mr. Burrill is at present managing the attractions which are being given at the railway company's park.

MR. C. B. FAIRCHILD AND MR. C. B. FAIRCHILD, JR., for many years connected with the STREET RAILWAY JOURNAL, have become associated with the "Street Railway Review," the former as New York business representative and the latter in the editorial department in Chicago. The heartiest good wishes of the STREET RAILWAY JOURNAL go with the Messrs. Fairchild in their new work, the kindest and most cordial feelings having always been entertained for them, and their value of their work having been fully recognized and highly appreciated.

MR. GEORGE J. GOULD, president of the Manhattan Elevated Railway Company, of New York, returned Sept. 23 from a trip to Europe. Mr. Gould, when interviewed regarding the plans of the company, said: "Everything is progressing nicely. We have already broken ground for the power house. The third rails have been purchased and the engines ordered. I cannot say, however, when the change will be made, but I can say that everything is going ahead in that direction. The Manhattan will soon give the people rapid transit, and that in the near future."

MR. E. C. FELTON, president of the Harrisburg Traction Company, has resigned that position to take effect Oct. 1. Mr. Felton succeeded Mr. John Q. Denny as president of the company upon the consolidation of the East Harrisburg and Citizens' Street Railway Companies as Harrisburg Traction Company a few years ago, and under his most successful administration the property has increased in value and earning power to a most appreciable extent. Mr. Edward Bailey, president of the Harrisburg National Bank and Harrisburg Trust Company and a director of the traction company, has been chosen as his successor.

MR. C. J. FIELD, consulting engineer and contractor, who has been for the past year and a half identified with the American Vitrified Conduit Company as general manager, has severed his connection with that company to accept the position of vice-president and general manager of the United States Motor Vehicle Company, with offices in the Townsend Building, at Twenty-fifth Street and Broadway, New York City. Mr. Field also proposes to continue his separate business interests as a consulting engineer and contractor on central station, electric railway and underground conduit work.

MR. DANIEL A. HEGARTY has accepted and entered upon his duties as general superintendent of the Railways Company General, with offices in the Drexel Building, Philadelphia. A pleasing feature of his return to Philadelphia from Norfolk, where he was general superintendent of the Norfolk & Ocean View Railway, was an informal dinner tendered him by his former associates in the Hestonville, Mantua & Fairmount Railway, of Philadelphia, of which he was general superintendent and chief engineer. It will be remembered that on this railway the employees remained loyal to the company during the great strike on all the other roads in Philadelphia in 1897.

MR. SHIMBA KUNISAWA, C. E., chief engineer of the Japanese Government railroad system, with headquarters at Tokio, sailed from New York for Japan, Sept. 27. Mr. Kunisawa was in this country about three weeks, and his visit was for the purpose of studying American railway methods in general and the condition of maintenance of shops in particular. Mr. Kunisawa, while out West, made a minute inspection of the Chicago, Burlington & Northern shops, and also those of the Chicago & Northwestern and the Chicago, Milwaukee & St. Paul companies, and expressed himself as having been highly delighted with the instruction which he received.

MR. H. WHITLEY, vice-chairman of the Borough Tramway Committee of the Halifax (England) Corporation, and Mr. H. F. Street, borough electrical engineer, arrived in New York via steamship "Servia," on Sept. 6. It is their intention to make a quite extended trip in the United States, investigating, in the interests of their municipality, the subject of electric traction, particularly with respect to the use of polyphase currents for transmission purposes. They will first spend several days in New York and Brooklyn, and then will go to Philadelphia, Washington, Pittsburgh, Cincinnati, possibly Chicago, Buffalo, Toronto, Montreal and Boston, returning to England early in October.

HENRY B. CUTTER, president of the Cutter Company, of Philadelphia, recently returned from Europe on the "City of Rome." He expresses himself as delighted with the results of his prolonged European trip. As the I-T-E circuit breaker is already well and favorably known in Europe, it was to look over the field rather than to begin operations which took Mr. Cutter abroad. In a number of the most important recent electrical installations, for street railway services particularly, the I-T-E circuit breaker has been specified. The Cutter Company has also been specially invited to bid on the circuit-protecting apparatus for the Metropolitan underground system in Paris.

DR. W. D. EASTLAKE, of Tokyo, Japan, has arrived in New York. Dr. Eastlake is an American, but has been in touch with Japanese business and professional life for about twenty years, during ten of which he has lived in that country, and has enjoyed

peculiar facilities for becoming thoroughly acquainted with its people, speaking, as he does, the Japanese language perfectly. He is now in this country for the purpose of making arrangements with manufacturers here, by which American goods can be introduced into Japan to good advantage, and is particularly desirous of handling electric railway apparatus and material, machine tools, mining tools and supplies and electric lighting supplies.

MR. THOMAS BARRETT, assistant general superintendent of the Metropolitan Street Railway Company, of Kansas City, died Aug. 26. Mr. Barrett was sixty years of age, and had been in the employ of the company for about thirty years. He began service with the company as a hostler, and by faithful service was successively made driver, barn foreman, superintendent of car repairs and lastly assistant general superintendent. His death is greatly mourned by all his associates, and especially by Walton D. Holmes, president of the company, who, in referring to the matter, expressed himself as follows: "Mr. Barrett was like a brother to my brother, and we have worked along side of him ever since we have been in the street railway business, and have always considered him our right-hand man. Faithful, honest and capable, he has served our road as no other could have done."

MR. STEPHEN HARVEY BENNETT, of Baltimore, Md., has announced his intention of entering the field of the street railway examiner and appraiser. Mr. Bennett's first business training was received in the counting rooms of Messrs. Fisher & Shaw, bankers, of Baltimore, which firm was instrumental in placing large amounts of securities on railways and other industrial enterprises throughout many sections of the country. Showing an inclination to railway interests, Mr. Bennett was placed by this firm in the position of treasurer of the Atlanta Railway Company, of Atlanta, Ga., which position he filled until his resignation, July 1. During his office of secretary-treasurer of the Atlanta Railway Company Mr. Bennett for a time filled the offices of treasurer and auditor of the Nashville & Suburban Railway Company, but later resigned this position. It is Mr. Bennett's intention to devote his energies to the physical and financial examination of street railways and allied interests, especially where consolidation is contemplated, and to undertake the procuring of capital for the building or extension of desirable railway properties.

MR. W. D. RAY, who has recently accepted the position of general manager of the Magann Air Brake Company, is 26 years of age, and for eleven years has been engaged in the electrical business. In 1890 he entered the employ of the Cicero Water, Gas & Electric Company, Oak Park, Ill., as electrician's assistant, and from that position went with the Chicago & Northwestern Railway, first in charge of the lighting plant at the Grand Central passenger station at Chicago and of the electric and pneumatic block signals, and later as electric light inspector of the Chicago, West Chicago, Milwaukee and other towns. In 1893 he associated himself with the electrical department of the World's Columbian Exposition as trouble man and inspector. The following year he became connected with the Standard Electrical Company, of Chicago, as assistant consulting electrician, engaged in the testing and designing of dynamos, motors and transformers. From November, 1894, to July, 1897, he was employed by the Everett Railway & Lighting Company, of Everett, Wash., first as superintendent and then as general manager. Mr. Ray is also known as an inventor and writer, and is joint author of a book on the practical applications of dynamo electric machinery.

CAPT. ROBERT McCULLOCH, retiring superintendent of the National Railway system, of St. Louis, and C. Nesbitt Duffy, late secretary of the same company, were tendered a farewell banquet by the employees of the Broadway, Southwestern, Baden, Citizens', Cass Avenue, Northern Central and Union lines, Aug. 28. Among those present were: C. H. Spencer, president of the National Railway Company; W. J. Orthwein, president of the underlying companies of the National Railway Company; Christian Peper, for many years president of the Broadway line; R. D. Ellis, assistant attorney for the railway companies; F. C. Whittemore, Messrs. McCulloch, Duffy and a few others. More than 300 employees of the railway companies sat down to the banquet, which was most elaborate. When all had partaken of the banquet, C. H. Spencer was made chairman and R. D. Ellis secretary of the meeting. In a short speech Mr. Spencer set forth the object of the gathering, and added a few words complimentary to the employees. Capt. McCulloch was then called on and thanked the employees for the expression of their feeling and spoke of his regret in leaving them. A talk of pleasant nature was also made by Mr. Duffy. Secretary Ellis then read resolutions prepared by the employees conveying the good wishes of all to Capt. McCulloch and Mr. Duffy. They were printed and handsomely bound and contained the names of all the employees of the lines. Several other interesting and short speeches were also made. Mr. McCulloch and Mr. Duffy, the day following the banquet, were waited upon at their homes by the employees. Mr. Duffy was then presented with an open-face watch, with his initials, the date and "From the National Railway Boys" engraved upon the back, and Capt. McCulloch was presented with a fine piece of Dresden china, decorated with a hand-painted Scriptural scene.

MR. W. A. McGUIRE, president and manager of the McGuire Manufacturing Company, is well known in the street railway industry, so that in a Chicago number the presentation of his portrait is most appropriate. Mr. McGuire has not only been the constant guardian and builder of the financial reputation which this company enjoys, but is also to be credited largely with the success of the company in other ways, as most of the patents which this company owns are the product of his mechanical genius. He has accumulated a very comfortable fortune, and might have retired many years ago but for the pride he takes in the company bearing his name and his apparent determination to see it one of the largest and strongest concerns of its kind in the world. A portrait is also published of Mr. W. J. Cooke, vice-president of the company, who has been with it from the start, and has shared its success. He has always cared for the selling interests of the company, and is one of the most popular salesmen in the field. His pleasant smile and genial manner have gained for him the sobriquet, the "Chesterfield" of railway salesmen of the country. Father Time has changed the color of his hair to a silvery white, but his bland smile and bright eyes are as attractive to-day as they were twenty years ago. At present the company is enjoying the largest business it has ever done. Not a part of the large factory but is filled with material and machinery, and, though the works are running night and day, they still are about three months behind with a large amount of work.

W. A. MCGUIRE

W. J. COOKE

AMONG THE MANUFACTURERS

EDWARD A. MEYSENBURG has resigned as an officer of the Badt-Goltz Engineering Company, and has retired from active management of this concern. This corporation was formerly known as Meysenburg & Badt (Incorporated).

DICK, KERR & COMPANY, of London, England, have received a contract for the entire equipment of the Calcutta tram-

ways, and their representative, Mr. Rutherford, has left for India to take charge of the work of constructing the line.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY has issued its September bulletin, numbered 2728. The bulletin is illustrated and describes in general the Bullock electric power system for operating newspaper presses.

WESTINGHOUSE, CHURCH, KERR & COMPANY, are out with a neat little brochure entitled "A Bird's Eye View of Our Business." This comes in concise form, and gives descriptions of the different types of Westinghouse engines and generating sets.

THE WALWORTH MANUFACTURING COMPANY, Boston, purchased property 130 to 136 Federal Street, and after it is remodeled the company hopes to have as convenient, well-arranged and handsome salesrooms and offices as any in Boston.

THE STANDARD AIR BRAKE COMPANY, of New York City, has a new catalogue, handsomely bound, showing the latest developments in standard air brake apparatus. The company's new compound compressor and automatic motor controller are described and illustrated.

McKEE, FULLER & COMPANY, of Catasaqua, Pa., manufacturers of chilled and steel-tired car wheels for electric railways, will have an exhibit at the Chicago Convention, showing their wheels and axles. It will be under the supervision and in connection with the exhibit of Elmer P. Morris.

THE WATSON-STILLMAN COMPANY, of New York, manufacturers of hydraulic tools, and particularly of jacks and lifts, describes its latest productions in a catalogue of 54 pages. A complete line of hydraulic jacks for street railway purposes is shown, including motor lifts, jacks and replacing jacks.

W. S. LAYCOCK, of Sheffield, Eng., a prominent manufacturer of railway cars and railroad appliances, has recently published a very tasteful catalogue descriptive of the specialties supplied by him. They comprise all kinds of railway fittings, including curtains, boxes, steam and electric heaters, etc.

REAVELL & COMPANY (Ltd.), of Ipswich, Eng., report an excellent demand for their high-speed enclosed constant-thrust compound engine, and although the company has entered the electrical field within a comparatively recent time its sales show that the engines are favorably regarded by electrical engineers.

GREEN'S fuel economizer seems to be equally popular for railway power stations on both sides of the Atlantic. It is noticeable that economizers are used in most of the large stations which are being built for electric railway service, and it is stated that this make of economizer has been fitted to upwards of 200,000 steam boilers.

THE ELECTRICAL INSTALLATION COMPANY, of Chicago, has closed contract and is about to begin work on 6 miles of single track and 3 miles of double track construction for the Birmingham Railway & Electric Company, Birmingham, Ala. This is the third contract this company has had in Birmingham during the past two years.

A VERY CONVINCING little circular is that issued by the B. F. Sturtevant Company, of Boston, Mass., regarding its exhaust heads, which shows that by the utilization of centrifugal force in the operation of this head, the water is thrown outward with 1000 times the force exerted upon the steam, and is thereby absolutely separated from it.

THE STANDARD ROLLER BEARING COMPANY, whose factory has formerly been in Boston, announces that it will very shortly move to Philadelphia, where it has commenced the erection of a new factory that will be 60 ft. x 100 ft. and four stories high. The company expects to have its new factory in operation within the next sixty days.

THE NEW ENGLAND RAILROAD CONSTRUCTION COMPANY, of Worcester, has just closed a contract for the complete construction and equipment of an electric line between Templeton and Gardiner, Mass., a distance of 5½ miles. The contract embraces the construction of the road, the power station, car house and everything complete. Work begins at once.

THE R. WOODMAN MANUFACTURING & SUPPLY COMPANY, 63 Oliver Street, Boston, states that it has never been so busy as at the present time. The Woodman steel ticket punch is one of the best known articles in the electric and steam railway field, as there are but few roads in America where they are not used to some extent. The company also manufactures uniform buttons, badges, etc.

THE DE WITT "Common Sense" sand box completes this fall the sixth year of its use on street railway cars. During this time it has constantly grown in popularity and is now well known and in use on a very large number of roads in Europe and America. The claim is made for it that it will work every time and under all circumstances, that it has no complicated parts to get out of order, and that it will last as long as the car body.

THE JACKSON & SHARP COMPANY, of Wilmington, Del., were the builders of the double-deck car used on the Syracuse, Lakeside & Baldwinsville Railway, and of which a description and engraving were published in the last issue of the STREET RAILWAY JOURNAL. This company has built a number of this type of car recently; these cars have proved very satisfactory, especially for summer service where large crowds have to be handled.

THE GREEN ENGINEERING COMPANY, of Chicago, reports that it has just secured an order from the West Chicago Street Railway Company for twenty chain grates to go under 8000 h.p. Stirling boilers at the Western Avenue station. This company has also received the contract for sixteen grates for the new plant to be built by the United Railways Company, of St. Louis. These contracts are said to be the largest ever made for chain grates.

THE AMERICAN VITRIFIED CONDUIT COMPANY, of New York City, is sending out a valuable catalogue, giving illustrations and descriptions of its vitrified salt glazed underground and interior conduits. This company is prepared to take contracts for complete installation of conduit systems. It has finished, within the past few months, a number of large pieces of work of this kind, including many thousand feet in New York, Providence, New Orleans, Boston, etc.

THE WILLANS central valve engine, manufactured by Willans & Robinson, Ltd., of Rugby, England, has proved a most popular type of engine for electrical service in Europe. This company reports 16,000 h.p. in use or on orders for electric traction in the United Kingdom. Among the parties using these engines are the Liverpool corporation, who have ordered eight engines of 1200 h.p.; the Bradford and St. Helens corporations, and the City & South London Railway.

THE MONARCH TRACK CLEANER, heretofore manufactured and sold by the Monarch Stove & Manufacturing Company, of Mansfield, Ohio, will from now on be handled exclusively by the Ohio Brass Company. There are already a large number of these cleaners in use, as they universally recommend themselves, whenever investigated or tried. The Ohio Brass Company is taking steps to push actively the sale of this latest addition to its line, and it is safe to predict satisfactory results to its efforts.

AGARD'S patent vestibule sliding door for electric cars, which is manufactured and sold by James L. Howard & Company, of Hartford, Conn., seems to grow in popularity. This device is in use on all closed cars of the Hartford Street Railway Company, and has given entire satisfaction after two years of use. Mr. Crawford, the general manager of the company, states that in his opinion it satisfactorily solves the vestibule door problem. Briefly, the invention substitutes a sliding door for folding doors.

THE STILLWELL-BIERCE & SMITH-VAILE COMPANY, of Dayton, Ohio, has established a branch office at St. Louis and contiguous territory, in room 601, Burlington Building. The office is in charge of Louis Bendit, and the company will carry at this office a full line of standard sized steam pipes and automatic feed pumps and receivers, air compressors, heaters, etc. The company is enjoying an excellent business just now in the manufacture and sale of the Victor water cooling tower for condensing purposes.

THE STURTEVANT COMPANY has recently published a tasteful illustrated catalogue descriptive of its blowers and exhausters. As is well known, the company makes a specialty of this class of machinery and supplies it in every size for all conditions of work and for either electric or steam operation. The company has done considerable work in Chicago, but perhaps as good an example as any is contained in the large works of the Siemens & Halske Company, of Chicago, which uses the Sturtevant system of heating and ventilation.

THE LESCHEN, MACOMBER, WHYTE COMPANY, of Chicago, has supplied many appliances used on the local street railway lines, as well as of railways farther from home. Among the goods which this well known firm has sold to the Chicago companies are trolley wire, weather proof feed wire, rubber insulated wires and cables, magnet wire, century tape, wire rope, galvanized steel stranded curtain cord and "Beacon" bearing metal. The company is agent for the Bibber-White Company, of Boston, and handles all the goods of that prominent supply house.

J. H. HOLMES & COMPANY, of Newcastle-on-Tyne, England, have met with excellent success in the manufacture and sale of the Castle dynamos, as well as their apparatus for electric lighting, transmission of power, etc. Special attention has been paid in the design of these machines to electrical and mechanical details, which secure not only a high electrical and commercial efficiency, but also prove satisfactory from a mechanical standpoint. The machines are built in all sizes, from 11 kw. up, and for direct connection or for belting. The firm is represented by L. W. Holmes, 17 Soho Square, London.

MATHER & PLATT, of Manchester, England, are doing their proportion of the electric railway work in England, and this proportion is a very large one, as is shown by the frequent installations of machinery of these manufacturers chronicled from month to month in these columns. The corporation of Mather & Platt, Ltd., makes slow speed generators for railway and lighting purposes, direct and alternating currents, boosters and balances, electric locomotives, generators, motors and controlling apparatus for electric power distribution.

GALES COMMUTATOR COMPOUND, which is manufactured by K. McLennan & Company, of Chicago, and is employed to reduce sparking, has been heartily indorsed by the managers of a large number of railway and lighting companies, including the Aurora (Ill.) Street Railway Company, Charlottesville (Va.) City & Suburban Railway Company, Niagara Falls (Ont.) Electric Light & Power Company, and the Dover (Maine) Foxcroft Light & Heat Company. The testimony of these users indicates that the compound increases the life of both commutators and brushes.

GEORGE E. FISHER, president and treasurer of the Chase Construction Company, general contractors, Detroit, Mich., has secured the contract for his company for constructing the Toledo, Fremont & Norwalk Railway, from Toledo to Fremont, Ohio, which includes all work outside of the power house and bridges. The company will employ a force of two hundred or more men on this contract. Mr. Fisher states that his company is now completing the large municipal electric lighting plant for the city of Grand Rapids, and the construction of the Cleveland & Eastern Railway at Cleveland, Ohio.

THE WESTERN ELECTRICAL SUPPLY COMPANY, of St. Louis, has recently taken the agency for the multiplex reflector. This is something entirely new, and is attracting much attention. It is claimed to be the most powerful street railway headlight made, and is guaranteed on competitive tests to be 300 per cent stronger than any other make of reflector, plain or parabolic, on the market to-day. This headlight is corrugated in such a manner that each corrugation acts as an independent lens, producing thereby a light of the greatest intensity. They are made in all sizes and styles.

THE WESTERN ELECTRICAL SUPPLY COMPANY, of St. Louis, will have a representative of its street railway department at the National Street Railway convention in Chicago this month. This department has in the past year become one of the most important branches of their business. Its growth has certainly proven phenomenal. The company, realizing that prompt shipments are a most important factor, is carrying what is probably the largest and most complete stock of street railway material in the country. The company has also gotten out a most complete and up-to-date catalogue devoted exclusively to street railway equipments.

THE WILKINSON MANUFACTURING COMPANY, of Philadelphia, whose automatic stokers have received so favorable a reception from steam users, reports that it has received orders, during the last two months, in the city of Washington for the equipment of 11,000 h.p. of stokers, and within the same space of time in the cities of Philadelphia, New York, Jersey City, Harrisburg, Wilmington, Coatesville and Camden orders for the equipment of 9150 h.p. The company states that the outlook for stokers of its make is very promising, and that it has sufficient orders to keep its works taxed to their utmost capacity, running day and night, for six months.

THE USE of telephones for car dispatching and signaling on electric railroads has increased to such an extent that the fact that the Garl Electric Company, of Akron, Ohio, makes a telephone especially for this work is of interest. This instrument is designed especially to overcome the heavy induction always found on electric lines, and, being simple in construction, is adapted for portable service. The company also makes an ingenious connecting box and pole for this service. In case a car should be disabled and away from any connecting box or hook, the telephone can be raised from the holder and carried to the nearest connection box or hook and connected from that point.

THE NAME OF T. J. WHITING & SONS, Limited, of London, is well known throughout Europe and the English colonies as manufacturers of tickets for tramways, omnibuses, etc. This firm has been established for over a quarter of a century, and numbers among its customers railway companies in every section of the world. A reference to this company's catalogue was published in a recent issue, and gives the best idea possible of the extent of the company's business. Reproductions of the tickets which the company has printed for all parts of the world, civilized and uncivilized, are given, and it would need an expert polyglot to read all the directions on the tickets reproduced.

THE H. W. JOHNS MANUFACTURING COMPANY, of New York, will exhibit at the Chicago Convention a full line of its molded mica overhead insulation, together with its "Noark" indicating fuses and car heaters. The exhibition will be in charge of its Western representatives, the Manville Covering Company, of 173 Randolph Street, Chicago, Ill. The company will also make a practical demonstration of its enclosed fuse, and intends to show something in this line far in advance of anything previously undertaken. It will have present at the convention at least six representatives from its Eastern office, and in addition to this the representation of the Manville Covering Company.

BULLOCK ELECTRIC APPARATUS continues to find favor, especially among the more exacting users. Sales reported by the company for August embrace fifty-two machines, ranging in size from 2½ kw. to 800 kw. capacity. The orders were widely distributed throughout the United States and two were from Great Britain. The latter were for the celebrated "Fraser" equipment for operating large printing presses; one 50 h.p. equipment coming from the "Free Press," of Aberdeen, Scotland, and four 50 h.p. equipments from the "Scottsman," of Edinburgh. The company has just issued Bulletin No. 2732, which will be forwarded to any one applying for it at its general office, Cincinnati, Ohio.

THE HOPPES MANUFACTURING COMPANY, of Springfield, Ohio, has just issued a new catalogue with handsomely designed cover. This cover shows an artistic arrangement of the company's vertical and horizontal separators and cuts of its live steam feed water purifier and a number of scaled pans showing their appearance as they come from the purifier when ready to clean. The interior of this catalogue shows the separators and oil eliminators, together with the live steam feed water purifiers and exhaust steam feed water heaters, but is more especially devoted to the former, together with special forms of separators and receivers. The pamphlet is well printed and will be of interest to any one who desires information in this line.

THE LOMBARD WATER WHEEL GOVERNOR COMPANY, 61 Hampshire Street, Boston, has orders booked for more than seventy water wheel governors, and has been running its works to their fullest capacity for the past year or more. By the use of the Lombard governor water power plants have been brought to as perfect regulation as the best regulated steam plants. A large number of orders have been filled for very difficult water power plants, where close regulation was an absolute necessity, and in every case the Lombard governor has met the requirements and given perfect satisfaction, in fact, there seems to be no longer any question as to the ability of this governor to properly govern the speed of a water wheel which is subject to large and sudden variation of load.

THE CROWDUS ACCUMULATOR SYNDICATE, of London, England, is meeting with great success in the manufacture of accumulators for traction purposes, especially for automobiles. The greatest care is taken in the manufacture of the plates to secure lightness and durability. The lead grids are stamped out by machinery, and are only 0.037 in. in diameter. They are then pasted with sulphate of lead and litharge, and then soldered to a back plate. In assembling the cell the plates are wrapped in an envelope of cellulose, and between each plate is placed a perforated sheet of highly absorbent material, which hardens when the fluid is put in and holds the plate permanently in position. The containing case is of ebonite, and the top is cemented on. The London factory has a capacity of 180 cells a day.

THE GREEN FUEL ECONOMIZER COMPANY reports recent sales of Green's economizers for the following plants, among others: Third Avenue Railway Company, Kingsbridge power station, New York (32,000-B. h.p.); Swift & Company, Chicago, Ill.; Dominion Cotton Mills, Montreal, P. Q. (fourteenth order); Great Northern Paper Company, Millensocket, Maine, and Madison, Maine (two orders); American Thread Company, Holyoke, Mass.; American Hard Rubber Company, College Point, N. Y. (second order); Richelieu Woolen Mills, Chembley, Canton; Worcester City Hospital, Worcester, Mass.; Knoxville Woolen Mills, Knoxville, Tenn.; Anniston Manufacturing Company, Anniston, Ala.; International Paper Company, Otis Falls, N. Y., and Nashua River Paper Company, East Pepperell, Mass. (second order).

GEORGE KISSAM, of George Kissam & Company, will attend the convention in Chicago as usual. He has only missed one in ten years, and is practically the only man in the street car advertising business who is always found at the annual meetings. Mr. Kissam states that the street car advertising business this year is in a very much improved state, and that his firm is making money for the first time since 1893. The largest branch of this firm is located in Chicago, where they control the advertising privileges of all the North and West Side cars, and have done so for over eleven years. They claim to have the largest business in street car advertising in the world, and control the advertising privileges in most all the principal cities of the United States. Their annual disbursements in this line for rentals are over $300,000.

THE WORTHINGTON PUMPING ENGINE COMPANY, of London, reports a large business in orders from electric railway stations in Great Britain and on the Continent. This company has branch offices in the principal cities of Great Britain and in Copenhagen, Calcutta, Amsterdam, Johannisburg, St. Petersburg and Sydney. It has also allied companies in Paris, Berlin, Vienna, Brussels, Buda-Pest, Milan, Naples and other cities. The company's cooling tower for condensing water, where a natural source of supply is wanting, can be operated either by fan or natural draft, and in connection with the surface or jet type of condenser, and is particularly adapted for railway stations, on account of the frequent necessity of locating such stations away from the most economical point for producing steam, in order to procure electrical efficiency.

J. R. McCARDELL & COMPANY, of Trenton, N. J., write that they will be well represented at the convention. Among other exhibits they will show one of their improved standard two-horse Trenton trolley wagons, with revolving platform and extension tower. This wagon has established a high reputation for convenience, ease of operation, durability, labor-saving qualities and general adaptability to street railway work. The company also expects to exhibit its new one-horse tower wagon, which is built on the same plan and in the same manner as the standard two-horse wagon, only much lighter. This wagon possesses all the good qualities of the standard wagon, and is adapted to all street railway requirements, except perhaps the heavier construction work, for which the Trenton standard wagon is intended. These two wagons will comprise the firm's exhibit.

AT A MEETING of the stockholders of the Erie Canal Electric Traction Company, held last month, the following directors were elected: Louis A. Von Hoffmann, of the banking house of L. Von Hoffmann & Company; William Mertens, of the banking house of L. Von Hoffmann & Company; Henry R. Ickolheimer, of Heidelbach, Ickolheimer & Company; T. C. Platt, president United States Express Company; Charleton P. Lewis, Mutual Life Insurance Company; John C. Carlisle, ex-Secretary of the Treasury; Frank H. Hawley, president of the West Indies Telegraph & Cable Company; William H. Baker, vice-president Postal Telegraph Company; George W. Balch, New York Produce Exchange, and James Virdin, Corporation Trust Company. The following officers have been elected: President, Baron Louis A. Von Hoffmann; vice-president, Frank W. Hawley; secretary, A. D. Donaldson.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., has the contract for furnishing the structural steel work for three buildings for the Ottawa Carbide Company, of Ottawa, Canada. The buildings are from three to five stories high, and consist of a furnace building 80 ft. wide and 286 ft. long, a grinding room 38 ft. wide and 80 ft. long, and a breaking room 35 ft. wide and 80 ft. long, and two stories high. The floors are carried on steel beams and columns, and the flooring is steel plate. The trusses have a clear span, and the roofing is corrugated iron. The bins for the storage of material are all of plate iron. No woodwork is used anywhere in the construction of the buildings. The Berlin Iron Bridge Company is also erecting an extension for the power plant of the Hyde Park Electric Company, at Boston, Mass.; a fireproof station for the Gloucester (Mass.) Street Railway Company, and a number of bridges for the Elmira & Seneca Lake Railway Company.

THE WESTERN ELECTRICAL SUPPLY COMPANY, of St. Louis, reports that in no department of its business have the effects of the good times been felt so much as in the street railway department. A street railway department was added to the company's general supply business about a year ago, and to-day the company claims to be the largest strictly jobber of street railway supplies in the country. It has a most complete line of agencies, embracing the best known and largest manufacturers of street railway supplies. Realizing that prompt shipments are the jobbers' key-stone to success, the company carries in St. Louis stock the largest line of street railway supplies in the West, and is now reaping the benefits of its foresight. All the factories being crowded with orders, the ability to make prompt delivery from stock gives the company a great advantage over the ordinary jobber or agent. The growth of this company during the past year has certainly been phenomenal. The company has gotten out a complete line of catalogues, embracing everything pertaining to the electrical supply business. Its special street railway catalogue contains a very complete and carefully compiled line of street railway supplies. It is thoroughly up to date in every way.

THE TRIUMPH ELECTRIC COMPANY, of Cincinnati, reports a large number of recent sales of electrical apparatus, among which were the following: One 25-h.p. motor to J. A. Fay & Company, Cincinnati, Ohio; one 125-kw. generator to Ottawa Street Railway Company, Ottawa, Ill.; five motors to Armour & Company, Chicago, Ill.; one 100-kw. generator to Grand Island Electric Light Company, Grand Island; one 50-kw. generator to Carlisle Electric Light Company, Carlisle, Ky.; one 35-kw. generator to Murray Electric Light Company, Murray, Ky.; one 25-kw. generator to Owingsville Electric Light Company, Owingsville, Ky.; one 80-kw. generator to Light, Heat & Power Company, New Albany, Ind.; one 25-kw. generator to Arcadia Electric Light Company, Arcadia, Ind.; two 50-kw. generators to Fargo Gas & Electric Company, Fargo, Dak.; one 25-kw. generator to Kanawha Electric Company, Montgomery, W.

Va.; one 25-kw. generator to Williamson Electric Light Company, Williamson, W. Va.

CLING-SURFACE is a name becoming pretty well known in the manufacturing world, if inquiries and sales are an indication. The Cling-Surface Manufacturing Company, of 145-151 Virginia Street, Buffalo, N. Y., reports that it has just established a branch in Johannesburg, South Africa, to meet the increased demand for Cling-Surface in that section from those who have been compelled to run their belts as tight as possible to prevent slipping. A recent letter from a prominent mechanical engineer says: "Being somewhat skeptical as to the virtue of any belt dressing, it was some time before I concluded to try Cling-Surface, and only after being driven to it, as our belts were badly over-loaded and showed signs of rapid depreciation. Your Cling-Surface was a complete revelation to me, and belts that formerly had to be run so tight as to cause a great deal of noise are now runninng slack and quiet, without the least evidence of slipping. I heartily recommend it for leather belting, for in addition to its increasing the pulling capacity of a belt, I find the belts are soft, and show a fine glossy, yet very clinging, surface."

THE UNITED STATES ELECTRIC SIGNAL COMPANY, of Newton Highlands, Mass., has lately been organized for the manufacture of automatic signals for electric railways. This signal has been thoroughly tested on some of the New England roads and is reported to be working in a very satisfactory manner. The signal operates from the trolley, is entirely automatic and is claimed to be absolutely reliable in all conditions of weather, it does not require oil and cannot burn out. Should the power be lost for a time, the signal will relight when the power is restored. There are orange and green lights at each end of block, and when a car enters turnout, one of these lights is lighted at each end of turnout. This enables the motorman to know whether the signal is working and whether he is following a car or one is coming from opposite direction. The officers of the company are: President, Charles H. Morse, superintendent Manual Training School of Cambridge, Mass.; treasurer, James H. Nickerson, president West Newton Savings Bank; secretary. F. E. Wither; manager, W. H. Rand. The factory and office are at Newton Highlands, Mass.

THE BURT MANUFACTURING COMPANY, of Akron, reports an increasing sale for the Cross oil filter, which has come to be recognized as a standard for railway power stations. With this, the oil can be used over and over again, and there is no waste, as every dollar's worth of oil is used up. The system upon which it is based is that of washing the oil as well as filtering it. The oil is first passed through a layer of waste, which collects all the heavier impurities. It then passes into a chamber filled with pure warm water, which is heated by means of a steam pipe. Very little steam is required, and if the filter is kept in a warm place it is not necessary to make any steam connection. The oil enters this chamber in a very thin film, by which every particle of the waste oil is exposed to the action of the water, which washes out all remaining impurities. It finally leaves this chamber in a finely divided state of separation, thoroughly mixed with water. From this point it passes through another stratum of filtering material, after which it is ready for use. The filters themselves are very substantially built, and are finished in a most attractive way, so that they form an ornament in any engine room. The company also supplies a gravity oil feed system for power stations, which is popular with steam users.

THE OHIO BRASS COMPANY'S materials have played an important part in the building and operation of many of the "electrics" in and about Chicago, and at least some of its products may be found on most, if not quite all of them. These goods vary in their character from such well known standards as the type D hangers, Jewell trolley slings, Spillman ears, and Globe strain insulators, used by the Chicago General, to the Emergency Hose Bridge, several of which were recently sold to the Chicago City Railway, and special bonding plugs which will be used in track bonding on the Lake Street and Northwestern elevated railroads. The Emergency Hose Bridge mentioned above is one of the most important specialties recently added to the Ohio Brass Company's line, and a description of it appeared in this year's June number of the Street Railway Journal. There are several roads whose overhead construction is made up largely, if not quite altogether, of the company's goods, that have lost their identity by consolidations, purchases, or otherwise after they were built, such as for instance, the Suburban Railroad built by Naugle-Holcomb, and the Northern Electric Railway; the latter road having used the Wood's flexible pole brackets for suspending the trolley wire. Among the regular and frequent customers besides the companies mentioned above are the Calumet Electric Street Railway, the South Side Elevated Railway, and others, whose purchases consist of the regular line of goods which are too well known, as a rule, to need further description to identify them.

THE AMERICAN ENGINEERING COMPANY, of Philadelphia, Pa., has recently completed the track and overhead work for the Newtown Electric Street Railway. The Newtown Electric Street Railway Company has leased the Newtown, Langhorne & Bristol Railway, which, in conjunction with their own line, gives a complete electric railway between Bristol, the largest city in Bucks County, and Doylestown, the county seat, a distance of 28 miles. The American Engineering Company is now rapidly completing the power house and transforming stations of this road. The company has also recently finished construction on the line of the Elmira & Seneca Lake Railway Company. This railway will connect Elmira with Watkins, and give visitors to the far famed Watkins Glen an opportunity to visit another glen reputed to be of greater scenic beauty, though not so far famed simply because of inaccessibility to it. This contract provides not only for the track and overhead work, but for an extensive power house and car barn at Millport. Still another line, which the company is building, is one between Battle Creek and Kalamazoo for the interurban line of the Michigan Traction Company. This line, with the spur to Gull Lake, makes a distance of 28 miles. The Michigan Traction Company now owns and operates the road in Battle Creek and Kalamazoo, and when the interurban line is completed, will have 50 miles of track. It is expected that cars will be running by Dec. 15. The equipment of this line, as provided by the American Engineering Company, it is claimed, will be superior to any interurban line in the State of Michigan.

Balance Sheet System of Accounts

The Account, Audit & Assurance Company, Limited, has worked out the details of a complete "balance sheet system of accounts" for use by street railway corporations, manufacturing establishments and business enterprises in general, which should be adopted by every corporation of this character, for by its means it is possible to always obtain a going profit and loss statement and balance sheet without the necessity of writing up the books especially to produce it. It is a simple system, based on scientific principles, and saves labor rather than makes it.

The company undertakes the reorganization of corporation accounting systems from the foundation up, and furnishes complete "specifications" with a chart of accounts showing at a glance the proper distribution to be made of any particular charge, and its relationship to the entire scheme of accounting. This is in itself a particularly interesting and important branch of the "installation" and a great convenience to bookkeepers.

The Account, Audit and Assurance Company has just reorganized the books of a number of street railway companies, whose managers are most enthusiastic over the results obtained therefrom, and say that they would not go back to their old system under any circumstances.

The Account, Audit & Assurance Company has just reorganmake expert examinations and periodic audit of books, and its reports are entitled to great weight as being prepared by accountants of long experience who are thorough masters of their business.

Proceedings of the Eighteenth Annual Convention

OF THE

AMERICAN STREET RAILWAY ASSOCIATION

HELD AT

Chicago, Ill., October 17-20, 1899

The eighteenth annual meeting of the American Street Railway Association was held at Tattersall's, Sixteenth and Dearborn Streets, Chicago, Ill., on Oct. 17-20, 1899.

President Charles S. Sergeant, of Boston, called the meeting to order at 11:20 A. M. on Tuesday, and introduced R. S. Taylor, City Attorney of Chicago, who, in behalf of the Mayor, extended the freedom of the city to the delegates in a short speech, in which he referred to the improvements which have been made in motive powers for street railways during the past ten years, and to the complex problems to be solved by street railway managers.

President Sergeant replied to Mr. Taylor's address in an appropriate manner, saying that he presumed that the association had never before had the freedom of so large a territory extended to it, and that he sincerely trusted that the members would not abuse the privileges accorded them.

The President: The next order of business is the calling of the roll. If it is the pleasure of the association, instead of taking time to call the roll, the official registration of the secretary will be deemed the calling of the roll. That has been the custom at the meetings for some time past, and will save us a great deal of time. I would inform the association that the executive committee has passed a vote that it considers that any American elevated railway company is eligible to membership in this association. We consider that the delegate of every member is a missionary at this meeting to bring in some other company, and the invitation is cordially extended at this time to all companies not members to join this association. We believe it will be for their good and ours, and we hope if there are any persons here representing companies not members of the association they will send in their application to the secretary.

The following companies then joined the association:

Pueblo Traction & Electric Company, Pueblo, Col.

Venice, Madison & Granite City Railway Company, St. Louis, Mo.

Atchison Railway, Light & Power Company, Atchison, Kan.

President Sergeant: The address of the president is next in order.

ADDRESS OF THE PRESIDENT

The American Street Railway Association—

Gentlemen: We are to-day assembled for the eighteenth annual gathering of our association, and for the second time we meet in this great and prosperous city.

I feel very deeply the honor which makes it my duty and pleasure to welcome you to Chicago in behalf of the street railway men of this city, whose generous exertions have provided us with all the essential elements for a profitable and enjoyable meeting.

What remains to be done lies in your own hands, and I may be permitted to urge upon you the desirability of a full attendance upon the business meetings, and a free and ample discussion of the papers which will be presented. In order that the time may be sufficient for this purpose, your executive committee has purposely restricted the papers to a smaller number than usual, and earnestly solicits your co-operation in giving them full audience and ample discussion.

As will be seen by the report which is to be submitted, the financial condition of your association is good and improving from year to year, for which happy condition we should not forget we are indebted to the efficient efforts of your officers in prior years when the bank balance was not so readily visible; nor should the generous support of our exhibitions by our friends, the supply men, escape our notice.

The devotion of one day of your convention to the especial purpose of visiting the exhibits, which has been arranged by your executive committee, will be availed of it is hoped, by every delegate, to the mutual profit of all.

Those gentlemen who met here in Chicago in 1883, many of whom are, I trust, present to-day, could have had little conception of the changes in their business which were to occur before the end of this century. At that time there were in Chicago street railways operating about 153 miles of single track. At the present time the mileage of the surface street railways of this city is about 736 miles, of the Chicago interurban street railways about 261 miles, and of the elevated street railroads about 100 miles, either operated or under construction, making an increase since your last meeting here of 944 miles of track.

This remarkable extension of street railways, their equipment with mechanical motive power, the unique union "loop" system, and the successful application of electric power in the elevated railway service, are not only a wonderful testimonial to the courage, energy and capacity of their projectors, but they have made Chicago a street railway Mecca to which we all may come to observe and learn. We are, therefore, to be greatly congratulated upon the advantages afforded us by the selection of this city for our convention.

The year which has passed since we met has presented some unusual features which are worthy of our attention. The tendency toward consolidation of small or competing roads into larger homogeneous systems has been manifested by many examples. With the introduction of electric motive power the old time horse railway company operating a few miles of track on two or three city streets has disappeared, and its larger successor has found necessary such changes in administration, such extensions of its system and service, that the advantages of combination with rivals have become more and more manifest. The street railway which formerly gave a short distance urban service, has found itself extended far into the country; the same car which disputes the passage of a busy city street with a truculent teamster, may an hour later be flushing partridges and grouse along the rural highway, stopping to leave the tired artisan at his country home, and bringing a healthful excursion within reach of the humblest family—thus the trolley car is rapidly filling a long felt want which was neither

within the power nor the disposition of the great steam roads to supply. All this means changed conditions with new responsibilities and emphasizes the need of consolidation.

To successfully amalgamate such properties and organize and operate them with due economy and a just regard for the needs of the communities to be served, require of the operating officials a high degree of experience and skill. The new problems to be met offer better positions to which those who are ambitous may aspire, and the wonderful rapidity with which this situation has been developed will be a lasting monument to the officials of our American street railways. The advantages of this larger growth are many, and perhaps not the least is a growing respect for the value and importance of the street railway industry, which we may all hope will ere long be recognized by just laws, which shall deal fairly and equitably with the relations of the street railways to the municipalities, and give to capital invested in urban and suburban transportation security and a fair return upon the investment.

Another of the notable events of the year has been the failure of a striking attempt at municipal ownership, with which we are all familiar.

It is greatly to be regretted that the year has been signalized by several very serious strikes and attempted boycotts. With the consolidation of systems the question of labor assumes a greater importance. The paralysis of all the transportation of a large city is a grave public calamity to be prevented by all reasonable means in the power of the officers and men of the transportation companies, and by the municipal authorities. The larger the system of any corporation is, the more necessary it is that its management shall firmly and wisely conduct its affairs, and the more impossible that the responsibilities imposed upon the management should be delegated to others. Does it not, therefore, devolve upon us who are charged with such responsibilities, to take the greatest care that our representatives before the public, the employees, shall always receive such liberal and just treatment at the hands of all our officials that they may feel their interests and ours to be identical, and may loyally work with us for the good service of the public and our corporations? Care in the selection and instruction of employees may, therefore, well engage our constant attention. We are all merchants in that we have transportation to sell and must present it in an attractive manner if we wish to retain our customers.

The good will of the community which it serves, seems to be an essential element of success with any public transportation company, and the best means to obtain that good will should receive our careful consideration. In this direction lies, I believe, a field of work for our association and for each and every one of its members, which may be far more fruitful for good than our technical papers or our exhibits of apparatus.

We are all aware of the wide difference of opinion which exists in the community as to the proper relation of street railways to the public, the service they should render and the burdens they should bear, and last, but not least, the returns they should expect upon capital. In the press and in educational and social reform institutions, much prejudiced opinion and misinformation is promulgated calculated to injure public service corporations, and in so injuring them, to deprive them of much of their ability to adequately serve the public. Is it not our duty, each and all, in our own communities and wherever else opportunity offers, to take steps to remedy this state of affairs? Let us seize every opportunity to refute these current fallacies, meet the self-styled "economist" on his own ground and show him that his "quasi-public octopus" is the greatest public benefactor and social reformer the world has ever seen!

Fair minded men will generally listen to both sides of any question, and the ignorance of even those who should be well informed as to our industry, is so great that mission work to disseminate truth is imperatively demanded.

I believe that work of this character has already been undertaken by one of our friends of the Chicago daily press, and that in so doing he has set a worthy example which we may beneficially follow.

One of the saddest events of the year was the sudden death, in April last, of our lamented friend M. K. Bowen, president of the Chicago City Railway Company. Beloved by all who knew him, ever ready to spare his valuable time for the aid and information of others who sought to learn from his experience, he was an honor not only to the corporation he served so well, but to the profession which will miss him so sadly. Ever faithfully interested in your association, his untimely death brings a feeling of deep loss to us all.

I venture to remind you of the work which our friends of the Accountants' Association have undertaken and are accomplishing. The importance of accurate and uniform accounts to the success of any railroad can hardly be overestimated. A thorough knowledge of accounts and of finance are essential qualifications for the administration of large properties. The work so far accomplished by their association, and their further deliberations, merit your earnest support, which will not only be beneficial to them but to each and all of the members of our association.

I wish here to express my appreciation of the cordial support and valuable work of your efficient secretary and executive committee. That our association may always be so fortunate is my earnest wish.

In conclusion, may I once more express my sincere appreciation of the honor which you conferred upon me by electing me to preside over this meeting, and bespeak your patience with my shortcomings. (Applause.)

The President: The next business in order is the report of the executive committee.

The Secretary: The report of the executive committee, as in past years, will consist of the reading of the minutes of the several meetings held during the year, which will show what has been done by your committee.

ABSTRACT OF MINUTES OF EXECUTIVE COMMITTEE MEETINGS

The first meeting of the executive committee was held at the Auditorium Annex, Feb. 6 and 7. There were present Messrs. Sergeant, Holmes, Lang, Yuille, Jones, Beggs, McCormack and Penington. The motion was made and carried that all members in arrears for dues for more than two years be served by the secretary with a written notice that if these back dues are not paid by Sept. 1, 1899, the executive committee will recommend to the association that such members be expelled in accordance with the provisions of Article XIX of the by-laws. The renewal of the treasurer's bond, issued by the American Surety Company, of New York, in the amount of $5,000, renewed to Feb. 1, 1900, was presented to the committee by that officer, and placed in the possession of the president. The original bond of said company, dated Feb. 1, 1898, which had been in the possession of President Lang was delivered to President Sergeant. The salary of the secretary-treasurer was continued at $1,500 per annum, as in the past years. The committee visited Tattersall's and approved the hall for exhibit and convention purposes.

The second meeting of the executive committee was held at the Auditorium Annex, Oct. 16 and 17. There were present Messrs. Sergeant, Moore, Woodruff, Lang, Jones, Beggs, McCormack and Penington. It was moved and seconded that the secretary write to all street railway companies eligible to membership which are not members of the association, inviting them to become members, in the belief that it will be to the mutual benefit of all concerned for them to belong to the association; also that in the sense of the executive committee any American elevated railway company is eligible for membership. The auditing committee, consisting of Messrs. Lang and Beggs, then rendered a report that they had examined the accounts of the treasurer and had found same correct. The report was accepted and the committee discharged.

Mr. Lang moved that inasmuch as the various technical papers, especially the street railway periodicals, devote considerable space each month to publishing legal decisions relating to street railways, that the publication of street railway decisions by the association be dispensed with. Motion carried.

President Sergeant read a letter from John T. Burnett, chairman of the special committee on the carrying of United States mail on street railways, in which he stated that the conditions during the year had not been opportune for effective work, and he believed that the committee should be continued for another year and given further time for action; or, if preferred, a new committee should be appointed. Mr. Lang moved that the executive committee recommend to the association that the committee on the carrying of United States mail on street railways be continued for another year. Motion carried.

Mr. Woodruff moved that the executive committee recommend to the convention the adoption of the following rules:

RULES OF THE CONVENTION

1. No member will be recognized by the president unless he shall announce distinctly his name and address.

2. Speeches will be limited to ten minutes unless the time shall be extended by the convention.

3. Members who desire to offer resolutions or other matters to be considered by the convention, are requested to submit them in writing, over their signatures, to the secretary.

Motion carried.

The minutes were approved and filed.

The President: We will now listen to the report of the secretary and treasurer.

REPORT OF THE SECRETARY AND TREASURER

Cash in bank, Aug. 25, 1898		$3,656.28
Receipts to Oct. 11, 1899		
Membership fees	$450.00	
Annual dues	3,930.67	
Space, Exhibit Hall, 1898	3,137.70	
Space, Exhibit Hall, 1899	132.50	7,650.87
		$11,307.15
Expenses to Oct. 11, 1899		
Printing and stationery	$1,649.33	
Postage	181.45	
Salaries	1,500.00	
Executive committee, 1899	383.12

DEATHS DURING THE YEAR

M. K. Bowen, president Chicago City Railway Company, Chicago, Ill., April 9, 1899.

William Penn Cooper, superintendent, Thirteenth & Fifteenth Street lines, Union Traction Company, Philadelphia, Pa., Feb. 23, 1899.

John H. Callahan, secretary, United Traction Company, Pittsburgh, Pa., Feb. 13, 1899.

DeWitt C. Cregier, ex-superintendent, Chicago, West Division Railway Company, Chicago, Ill., Nov. 9, 1898.

William E. Hale, treasurer, Toledo Traction Company, Toledo, Ohio, Nov. 16, 1898.

Joseph S. Lawrence, president, Charleston Consolidated Railway, Gas & Electric Company, Charleston, S. C., Aug. 5, 1899.

Charles F. Orthwein, vice-president Southern Electric Railroad Company, St. Louis, Mo., Dec. 28, 1898.

Austin Ely Smith, treasurer and general manager Springfield Street Railway Company, Springfield, Mass., Aug. 8, 1899.

Sylvanus M. Thomas, president and treasurer, Taunton Street Railway Company, Taunton, Mass., Nov. 20, 1898.

George Henry Wheeler, ex-president, Chicago City Railway Company, Chicago, Ill., Aug. 11, 1899.

Mr. Wyman, New Orleans: I move that the report be accepted. Carried.

The President: There is at least one committee report, which will be presented at a later session. We now have the pleasure before us of listening to a paper by the Hon. Chas. T. Yerkes, entitled "Investments in Street Railways: How Can They Be Made Secure and Remunerative?" [This paper appears elsewhere in this issue.]

Mr. McLean, Toledo: I move that the thanks of the association be extended to Mr. Yerkes for his able and interesting paper, and that it be entered in full on the minutes of this meeting.

The motion was unanimously carried.

The President: Personally I wish to thank Mr. Yerkes also for the very able paper he has given us and for explaining his methods of getting at the real essence of the whole financial situation of the operation of street railways, based upon his experience, as they have been developed in this paper. I am sure it will be a most valuable lesson to us all. The paper is now open for discussion. I will call upon C. D. Wyman, of New Orleans, to open the discussion.

Mr. Wyman, New Orleans: I think that by the vote you have passed, in which I most heartily join, we have expressed our sentiments touching this paper most sincerely; I felt when I saw such a topic had been assigned by the committee having that matter in charge for presentation at this time, that it was a topic which was of the greatest importance, and which we might congratulate ourselves would be presented at this meeting, but especially did I join with you in that pleasure which I know you all experienced when it was announced that Mr. Yerkes would read a paper upon that topic—a gentleman who has been so thorough a student of street railway enterprise, both from the financial and operating side. It seems to me also a work of supererogation on my part to attempt to add anything to what he has said upon this subject. But I will venture to say a word or two upon some lines which may possibly touch us as managers in our relation to our stockholders, our investors, that we have all duly considered, and yet which might be proper to suggest in connection with the lines of thought that Mr. Yerkes has presented.

Of the importance of sustaining and preserving the confidence and the faith of investors in the enterprises in which we are engaged there can be no question. When it is remembered that one-third of the invested wealth in civilized nations is to-day placed in steam and street railroads, and not an inconsiderable portion of that investment is in the street railroads, that we should secure and hold the confidence of our investors and that we should make their investments profitable is very evident. The great search which now is manifest on the part of capitalists to put their money into street railroad enterprises is one which should be met by a corresponding effort on our part to make everything plain, clear and distinct to them in regard to such

enterprise. In choosing a board of directors from among our stockholders it is always customary, of course, to select men not only of financial responsibility in a community, but we always regard it as necessary and proper to select men of high probity of reputation and of position. And if upon the officials of the company, the managers and the directorate, there is made emphatic in the eyes of the public this feeling of responsibility to the public and also the equal responsibility to their investors and the capitalists, the impression is wise and beneficial, and tends, moreover, to the extension and expansion of our business; for I take it in this respect, at least, we are all expansionists.

I remember reading in the paper that a distinguished orator here in Chicago, upon the occasion of a great gathering recently that was discussing trusts, said that in his opinion any danger on the part of aggregated capital might be warded off if there was a sufficient amount of publicity given. There is one thing that I respectfully submit to you in this matter, as my belief along this line, and that is that we should be frank, free and open with our investors; that we tell by means of circulars, of statements, of various methods of publication, of our operations and results, and state the truth, the exact truth as near as we can ascertain it, to all those interested in our respective companies, whether they be interested to a large or small extent.

While it is possibly true that complete disclosure at all times of the policy of the company might thwart it unjustly and unreasonably, I still do hold to this idea, and I am very glad to see, by publications made recently, much more so than a few years ago, that the results of our work are being set forth constantly and freely, and I believe that the more this is done in a proper and complete manner the more we shall secure and retain the confidence of our investors and secure likewise their further investment with us.

We often have what are known as "panics," a sort of neuralgia that pervades the financial market, and the usual reason given to us (we, perhaps, are not so thoroughly skilled in such matters) is that it springs from a want of confidence, that actual values are not disturbed, speculative values are, but that it results from a want of confidence, a fear, a distress, an uncertainty as to what is going on. Credits are withdrawn.

We may to some extent ward off any such feeling, any disquietude on the part of our investors, by letting them know the facts so far as we are able to do it, and give them frankly and freely our judgment as to our present condition, and our anticipations of the future with reference to the enterprises with which we are connected. I also believe we should adopt, so far as possible, a plain, simple and thoroughly understandable method of bookkeeping, and I am therefore most heartily in accord with the Accountants' Association now in session, who are endeavoring to do precisely that which I am endeavoring to describe. The average stockholder oftentimes becomes very much muddled when he attempts to study out the question of what shall be charged to operating expenses and what to permanent betterments, and, therefore, to invested capital. So far as it is possible, such a system of bookkeeping and recording of expenses should be adopted as will make everything clear and thoroughly comprehensible to his mind. I would also suggest in this connection the question of depreciation and the providing for same. I am exceedingly glad to see that some of the railroads, and notably the Milwaukee Street Railway Company—presided over by so able a manager as Mr. Beggs—have taken up this question of depreciation very carefully, very particularly, and have taken into account the depreciation of the different mechanical parts entering into the physical equipments of the roads. They are setting aside annually, as I understand it, a certain amount of money from their receipts to make good that depreciation.

Many electric railroads, or for that matter, cable railroads, recently converted from horse lines, are liable to lose sight of this fact for the first few years of their operation. Their receipts naturally increase and their expenses may be at a very low ebb, by virtue of the fact that everything they have is new and the era of repairs has not set in. It seems to me, therefore, that it is unsafe from the results of that particular year, or some other year, to predicate what the earning power of the company is going to be, or to tell stockholders that these results may be always expected. While it is always to be hoped, of course, that the increase of receipts will take care of the repairs and depreciations, it is, nevertheless, desirable if we can make certain and absolute that point by studying out what this depreciation is, what this life of the equipment is going to be, and we are at least on the safe side if we begin to provide for it, and tell our investors that that is what we are doing from the initial roll of the first wheel on our line. I think this subject is very important. The average net receipts for the years as they pass should be made up on such basis, and in that statement of average net receipts should come a careful estimate of the amount of money necessary to replace the rolling stock, power-house and miscellaneous equipment, after its life shall have been exhausted, and then a certain amount should be set aside; it may be very certainly fixed,

It is now some years since electricity, or that form of motive power which the major portions of the roads are now using, has been in our hands, and it is therefore by no means a difficult matter to come within a very fair average of the life of these different mechanical appliances and devices, and the material which we use in our different operations. Some time, possibly, we may be put under pressure to hasten matters, but I think a conscientious, firm, truthful, frank and honest management, while it may be criticised as being too conservative, had better err upon that side rather than the other. (Applause.)

Mr. Beggs, of Milwaukee: I feel very deeply interested in this subject that has been so ably presented here by a gentleman who has spent almost a lifetime in the ownership and direction of street railway affairs, and I feel so deeply interested in it because I am in a condition similar to that stated by Mr. Yerkes. I am charged with the responsibility of managing what is becoming one of the larger street railway systems of the country, but I am more than that, and have, therefore, given to this matter the most close and careful thought, because I can say, with Mr. Yerkes, that all I have in the world is in street railway property.

I think there is a side to this question that has not been touched upon in Mr. Yerkes' paper, even so thoroughly as he has discussed it, or in Mr. Wyman's analysis of it, and I desire to throw out that thought here. It is one which, as my friend, Mr. Wyman, has suggested, the Milwaukee company has taken hold of. I want to know that when I have been laid to rest, those to whom I may leave the results of a life of hard work will have some protection for the payment of these securities when these short-term franchises have ceased to exist. Taking the property of which I am now speaking, the franchises have a little over twenty years to run, and yet we are discussing the question now, as they are in some other sections of the country. We are trying in advance to make calculations as to how much we are justified in putting into that property and how long we have in which to get a return from it. I do not know that it is being done so methodically by other companies—it may be. We have calculated, and I believe you will recognize that this is a proper charge against earnings,

that you have a right to set aside a sum for this purpose before the public can demand that you shall give greater accommodation for the carrying of a passenger 12 miles to 15 miles, to which Mr. Yerkes has alluded, or that the fare shall be reduced. We are setting aside a certain amount for this purpose, to be paid to those who may succeed us in our investment in these properties, and so that, after the twenty years expire, they will not simply have turned over to them, out of which to recoup their investment, a pile of junk on the streets, that the city wants to return in order that it may make a better dicker with some one else. I feel that we have a good investment in the property if properly run. When a road is new and the equipment requires very few repairs it is not usual to look forward to the time when 45-lb. rails must be taken out and replaced with 80-lb. or 90-lb. rails, nor to the time when we shall be taking off the single-truck cars, the cost of which is $2,900 each, and replacing them with cars costing almost four times as much. The thought which I wish particularly to present here is that we must make some provision for the time that these bonds of ours will mature. In the case of the Milwaukee property, this does not occur until two years after the expiration of the franchise.

Now, as to the other point suggested, the security. Because I do not want to have anything to do with a thing that I cannot put my own means in, I want to know what provision has ben made to pay these bonds. Is there any sinking fund being set aside by your companies to take care of these various investments when they shall mature? Gentlemen, you must make proper provision for your properties by looking forward a very few years, when they will have to be thoroughly reconstructed from the ground up. I estimate that we replace 10 miles of track every year, and that is not at all conservative, because we have about 150 miles of track in the city limits, and I estimate that it will last fifteen years, which no track has done thus far. We must, therefore, put down 10 miles per annum to make it good. We estimate our rolling stock in the same way. It is a wonderful thing to tell, not only to the specialist, but to any business man or to any court, and it was very influential in the argument where the city tried to make us give 4-cent fares, that with proper maintenance of our system we could not do it. If we had taken the figures as they appeared on their face, our earnings would have seemed to be sufficient to warrant a reduction in fare, but they were fictitious, they did not represent our normal repair condition as it was. I desire, gentlemen, to impress upon you the necessity, in order to make these securities safe, of having the public take them as they do our waterworks and gas stocks, in nearly all of which the charters are perpetual. The longer our franchises have to run the more we can afford to spend upon the betterment of our systems and the greater the facilities we can give. We are merely merchants, as Mr. Yerkes stated, in selling transportation, and we must make a practice of "provoking the public to ride." It seems necessary in order to give security to these investments to make some provision for the bonds when our franchises have expired, and when we cannot earn the interest on them, to say nothing of paying the principal.

The President: We should like to hear from Mr. H. H. Vreeland, of New York, on this subject.

Mr. Vreeland: I had hoped that our president could have waited until a little later before calling upon me, because it is placing me in rather an embarrassing position, calling upon a boy to talk in the presence of a lot of men. I am but a child in street railroad work, and it seems that anything that I might say in the way of analysis of the very valuable paper of my friend, Mr. Yerkes, would be criticising the pioneer and the patriarch in street railroad work. I have learned since my connection with the industry that of the few men who started their life's work in connection with street railway interests, who have invested their money as they made it in the interests which they had created, who have followed it up as a life work until it reached a success far beyond what was considered possible for men to attain in any line or calling years ago, Mr. Yerkes is really the pioneer in that direction.

There is a thought in connection with Mr. Yerkes' paper that occurred to me when he suggested the question of management, the consideration not only of the average revenues, but the average of expenditures; that is one of the very strong points that appeals to the confidence of investors and the general public in properties. The great steam railroads of this country, with which the greater part of my life has been spent—you have only to mention the Pennsylvania, the New York Central, the New York, New Haven & Hartford and roads of that class to know what I mean—have created a confidence in the permanency of their managements. Secure the proper man to manage the property. This is really more important in street than in steam railroading, from the fact that in the steam road the directors do direct. There is not very much done in street railways in that direction. The manager is elected and put to work and allowed to run the property. He does not get much help, and he has to be a man who can meet the local municipal conditions, the State conditions and the general conditions as affecting the properties so far as legislative and municipal affairs are concerned. He has to be a man who can take care of the financial part of the operating side, and he has to do it with very little assistance.

The next thought that occurred to me was what my friend, Mr. Wyman, suggests, and it is a very important one—the question of publicity. Coming out of the school where we are taught—were taught for years—not to submit a report to your directors or president without analyzing it thoroughly, not simply showing that their train tonnage increased so much, mileage increased so much, revenue decreased so much, but went to work and analyzed it, and the same with reference to passengers—coming from that school then, I was surprised to find how very little of that there was connected with the street railroad system. In many cases, in the early days, there were good reasons for this, because usually two or three men ran the railroad and for years would act in the same manner as they would with a country store, and divided the money in the drawer among themselves. But the effect of consolidation and merging of the railroad interest in this country, both of steam and of street railroads, where 946 properties have been consolidated within the last ten years, irrespective of what may be termed trusts or monopolies, have changed this. The consolidations have reached a point where, by reason of recapitalization and reissuing of bonds necessary, our securities have come into the hands of the investing public, and the managers are the care-takers of the property, not of the few, but of the many. But it is necessary to let people know what they are buying and what values they are getting to determine whether it shall be made into a fund or be a different proposition. The number of the stockholders in the large corporations, I am glad to say, is increasing very rapidly in the different properties with which I am connected. The increase in the average number of stockholders has been very large. In the Metropolitan Street Railway Company the increase has been over 150 per cent in the last ten or fifteen years, both in the increase of capitalization and the bringing in of new investors. At the present dividend we had 130 more stockholders than we had at the last dividend three months ago; not one of them held over 100 shares of stock, and they are residents of New York City. That is one of the greatest

elements of strength in the handling of this property where we have to meet with the municipal and State question—a common interest with citizens in our properties—are located in the properties themselves. It assists and helps out with the question, gains friends for the property and assists very materially in the management.

With the question of twenty-year franchises and twenty-five-year franchises, I am glad to say that many years ago my predecessors were granted permanent franchises. Lately (though after we had secured such permanent franchises as are necessary for the handling of the business for the territory where we operate), the State Legislature decided to limit all future franchises to twenty-five years, so that it is not a question for me, as manager of the property, seriously to consider, but it is a very serious question for the other fellows.

There is one further point that Mr. Yerkes suggested, and that is the labor question. It is the life of the street railroad. All other matters connected with the property are insignificant. The financial side, the transportation side, except as represented by labor, are insignificant as compared with the great problem of handling labor. In the large consolidations there are, say fifteen or twenty different lines in which the employees have been handled under the theory and ideas of as many different managers, and you see how difficult it is to bring that body together, to try to get them responsible to one man and responsive to one method of management. It is a thing that requires a great deal of energy and ability, but it is a thing which, if once accomplished, gives the public to understand that the manager is managing the labor problem and not the agitator. And if you can get that confidence you must adopt the same policy as the agitator and take the platform as he does when he talks in his interests, and make up your mind that it is just as important for the manager to go on that platform and talk to them in his interests; that is one of the greatest elements of strength in the street railway question in my mind. I feel that it is one of the things to do in consolidating properties, and that the success that has come to our property is largely attributable to this. The success of the investment is in the confidence of the stockholders and the general public that no crisis is going to confront the property this year or next, that may not only wipe out the dividend, but mean the elimination of the entire earning capacity for that period and the disturbance of all the smooth working conditions that are necessary at all times.

Mr. McLean, Toledo: I feel amply repaid for attending this convention and listening to the discussion already had upon the very able paper of Mr. Yerkes, and without taking up the time of the convention, I think it proper to say that the paper itself and the discussion had upon it open up a train of thought which we can carry home with us, and which will inure to the benefit of the properties with which we are all identified. (Applause.)

Mr. Foster, Lynn: I feel entirely unequal to expressing to you my opinion upon this subject, although I have listened with a great deal of interest to the very able paper read before the members of the association by Mr. Yerkes, and I have also been interested in the very able discussion of the gentlemen who have preceded me. I agree with them that it is a subject of very great importance; but it appears to me to be a subject of far more importance to those operating street railways in the Western countries than it may be possibly in Massachusetts. In Massachusetts we have a Board of Railroad Commissioners, who have supervision of the movements of the street railways. Our tenure of franchise is entirely different, as I understand it, from what it is in this section of the country. There a franchise is granted to a corporation without limitation. To be sure, it is subject to revocation by the local boards, approved by the railroad commissioners. Of course, it would seem absurd on the part of the Board of Railroad Commissioners to revoke a charter on which they had approved the issuing of securities. Their approval is set upon the securities as a seal, and they have the power of limitation on the amount of securities which are issued, or may be issued. I understand that not to be the case in the Western States. It would seem that you are justified in seeking some better protection than what you now enjoy. I do not say, gentlemen, that the laws of the State of Massachusetts are superior for the operation of street railways than those of any other States, but I do feel that the investors are protected. It is frequently remarked by those offering securities of the home companies in Massachusetts that it is a dividend paying stock and it is free from taxation, making it a very desirable investment. A person holding street railway stock in any of the home companies, I believe to have a security which will justify any one in investing in it on account of its permanence. To be sure, we are subject to the caprice and whims of the local authorities to a certain extent, but that is limited by reason of our right of appeal to the Board of Railroad Commissioners.

Mr. Yerkes, Chicago: May I be permitted to ask the gentleman a question on one point he made? I understood from him that the grants of street railroads are liable to revocation at the instance of the local authorities, confirmed by the commissioner. Is it not a fact—and this I merely ask for information—that the courts have decided that these revocations cannot be put into effect unless it can be shown that the roads are not needed by the people? That was the point I wanted to make. According to your argument, Mr. Foster, it would seem as though at any time the municipal authorities and the commissioners could get their heads together, and could compel all the tracks in any town in Massachusetts to be taken up.

Mr. Foster: They would have to show that public necessity and convenience required the removal of the tracks; otherwise they could not do it.

Mr. Yerkes: It would be a pretty difficult thing to get the tracks up after the people once became accustomed to the use of the cars.

Mr. Foster: I do not know of its ever having taken place, except in one instance. I think there was a leased road where they undertook a revocation of the location; it was revoked and another was substituted for it. It was not a complete revocation.

The President: We do not want to hear from one section of the country alone. I may, perhaps, recognize the face of some gentleman because he lives in New England; I think we want to hear from all parts of the country. The South is represented here, and I believe we would be glad to hear from F. G. Jones, of Memphis, and other gentleman from the South.

Mr. Jones, Memphis: I think everything has been said that would be of any benefit, so far as my ideas go. We certainly have gathered very considerable information for us all in the line of making investments productive to people looking for that sort of securities. I do not believe it will be possible for me to add anything that would be interesting on the subject. We have certainly gathered some points and ideas that are new to us on the line of these short franchises, from our friend from New York, who gives us a pretty good idea that some of the larger companies there have gone in and succeeded in getting perpetual franchises. These arguments are going to help us in our territory when we come to ask for further extensions, and that, among other things, has been very gratifying to me. (Applause.)

The President: I see in the rear of the room a gentleman from whom we ought to hear, N. H. Heft, of Meriden, Conn. I am sure he has had a large experience in steam railroads, and possibly he can give us some idea on this question.

Mr. Heft, Meriden: While my time has been given to the building of electric railroads, I have not been required to direct any of my energies toward raising the money to pay for them. Our board of directors has done that. I have simply directed my energies to seeing how I could best spend the money to make the investment more desirable, and while I believe it is necessary to sustain harmonious relations with municipalities and with the State Legislatures, and with the public in general, I believe that the greatest benefits will come to the street railroad through mechanical and electrical engineers in improving the present equipment of the road. I believe that sufficient attention has not been paid to this matter, and in a great many instances we have run mad on the question of rails and the question of car equipments. In going over the questions of weights to-day I was horrified to find that for every paying passenger hauled with the modern street railway equipment we were drawing 721 lbs. of dead weight, exceeded by the steam railroads only to the extent of 137 lbs. with their standard steam railroad equipment. I think it behooves all street railroad managers to turn their attention to the question of equipment, to see if they cannot get rid of some of this weight. We expect to operate within the next two months a car whose weight, including the entire equipment, will not exceed 227 lbs. per passenger.

I have been very much gratified in listening to the paper of Mr. Yerkes, and also much interested in what our friend Mr. Wyman has said. He is always good, and I have also listened with a great deal of pleasure to our friend Vreeland, of New York.

The convention then adjourned until 10 o'clock Wednesday morning.

WEDNESDAY'S SESSION

President Sergeant called the meeting to order at 10:10 A. M.

Secretary Penington then read an invitation to the delegates from the Siemens & Halske Company to visit its plant. The secretary also announced that the excursion to the drainage canal would take place in the afternoon, and that the special train would leave the Dearborn Street station at 1:30 o'clock. The secretary also stated that as there was nothing on the programme for the evening, it had been arranged that the ladies should meet and go to the exhibition hall in a body to view the exhibits.

The President: The first paper upon our programme for to-day is a paper entitled "Maintenance of Car Equipment," by J. H. Vander Veer, superintendent of motive equipment, Brooklyn Heights Railroad Company, Brooklyn, N.Y. [This paper is published elsewhere in this issue.]

The President: The thanks of the association are due to Mr. Vander Veer for his able paper. I trust that it will be very fully discussed by all the practical and unpractical men who are here, but I do not think there are many unpractical ones. I desire to call on some one to open this discussion, and I will ask E. G. Connette, of Nashville, Tenn., to do so.

Mr. Connette, of Nashville: My primary education in the railway business, having been with steam railroad systems, has probably diverted my mind in a different direction from the opinions of some street railway people in regard to the inspection and maintenance of street car equipments. You all know that after a locomotive makes one trip, perhaps, of 100 miles or 150 miles, possibly 200 miles, it enters the round-house and is inspected, cleaned and all necessary repairs are made before it makes its next trip. So on the line with which I am connected. I adopted the method that when a car comes in from its work at night, having run perhaps 100 miles to 150 miles, it is first cleaned, then inspected. All the parts of the motor, including the wire connections, the brush contacts, and all the parts of the truck, are properly inspected, loose parts tightened up and all minor repairs made to the car, and it is prepared then for its journey on the following day. My experience with that method for perhaps ten years justifies me in saying that it has been entirely satisfactory. It is argued by some that daylight inspection is better, because the men have a better opportunity to see what they are doing, and feel more like working in the daylight than they do at night. That is true to a certain extent, but with a limited car equipment, and, perhaps, with the car-houses located in such a manner that it would be inconvenient to have the cars run in during the day from time to time to have the inspection, cleaning and repairs made, it becomes necessary with some companies to do the work at night. To a large extent this is the case with the system in Nashville, but, as I stated, the system of cleaning, inspecting and making minor repairs at night has been very satisfactory. If a car goes out in the morning and something occurs to disable it and it is brought into the shed, and it is found that the defect was caused by a lack of inspection, proper action, of course, is taken. That is an incentive to the night inspectors to do their work properly, because if they do not do it, results will tell. The general overhauling is done by the regular repair force by daylight, and we make it a rule to have the motors generally overhauled perhaps once in six months. About two years ago we had a very large exposition in Nashville, the Centennial Exposition, in commemoration of the one hundredth anniversary of the admission of Tennessee into the Union. During that period we hauled a very large number of people, using trail cars behind every motor car, with a headway of from one minute to 1½ minutes regularly, and during the six months of the Exposition there were but six motors disabled. I think that record will justify me in stating that the application of steam railway methods to street railway service has been entirely satisfactory to our company.

W. E. Harrington, of Camden, N. J.: I represent the Camden road, on which we operate at this time about forty-three cars, and do the bulk of our inspection and minor repairs at night. We do the general repairs, the carpenter work and painting work on the piece-work system, which has proven very satisfactory to us. One of the difficulties in adopting the piece-work system was in establishing prices for the work, not having any precedent, and we struck upon a method of covering possible mistakes in prices by limiting the amount of bonus that we would give in this way: If we set a contract price for a piece of work, say $5, and the work was actually done for $2, that would make a profit of $3, which would be entirely disproportionate; so we settled on a limitation of 20 per cent of the actual cost. If the work cost $2 and the contract price is $5, the actual bonus would be 40 cents; whereas. if the cost exceeded $5, the loss would not exceed 20 per cent of the actual cost price. That seemed to satisfy the shop-men, and enabled us to settle quickly this question, and it has been very satisfactory in its operation. We followed this same practice in our construction work, as well as the repair work, and in every respect it has been very satisfactory.

The matter of car cleaning and washing with us is a very serious matter, on account of the great amount of dirt and dust which we have in the territory through which our cars run. We do our car washing at night, and do that also on

the piece-work system. We are washing 18-ft. bodies for 15 cents a car, sweeping them out, dusting them and washing them thoroughly, and double-truck cars for 22 cents. The cost formerly was 40 cents to 60 cents for the same cars. We have got the cost down to these very low figures, and the work is being satisfactorily done. A point upon which I would like to get information is what is the general experience of the members in reference to the number of cars that are housed for repairs, taking the percentage of cars housed for repairs in proportion to the total number in operation. On our road the average is 10 per cent of the number of cars in operation, which are sent to the shops for repairs. I think this point should be brought out thoroughly, as it is a guide to know how many equipments to provide, and I think it is a point which should be generally discussed.

Mr. Vander Veer: In regard to the allowance of 10 per cent as the number of cars housed for repairs, we find on the system in Brooklyn that on some lines it will average 10 per cent, but on others it will go as low as 4 per cent, depending a great deal on the service and the equipment we have at the particular depot. I think 10 per cent of the total number of cars is an extreme limit.

Mr. Harrington: What effect would the question of having single-motor equipments and double-motor equipments on any ordinary road have on that percentage? We are running single-motor equipments, and I know that our depreciation is relatively high on our armatures and motor parts, and I ascribe a great deal of the percentage stated to be due to that fact. What is your experience in that matter?

Mr. Vander Veer: I have fortunately had nothing to do with single-motor equipments during the last few years, but my recollection is that it is much higher than the percentage stated. It will run higher than 10 per cent for single-motor equipments. Of course, the miles run per day and the style of motor will have a great deal to do with the question.

E. C. Foster, of Lynn: I would ask the gentleman if he considers there is any economy in operating a single-motor on an ordinary car? As I understand the situation now, this gentleman has been speaking of disabled cars which are lying in the car-house during a part of the day, and this disability, as I understand it, is due to defective apparatus. He says that 10 per cent of the cars are in the house all of the time. It seems to me if that is a fact we should go into the subject further, and ascertain if there is any profit in running single-motor cars. I would say for the benefit of the association that our experience on a suburban and interurban road is that we have not found it profitable to operate single-motor cars, probably on account of the increased expenses incurred in the maintenance of them as compared with the double-motor cars. This past season we have been operating one ten-bench open car with a pair of G. E.-57 motors, each having a capacity of 52 h.p., making the two motors 104 h.p. That, you will recognize, is an excessive amount of power to operate a ten-bench, single-truck car. But the results, so far as repairs have been concerned, have been very satisfactory, no repairs being required on that car during the entire summer. We have not even worn out one pair of brushes, although the car has made about 120 miles a day. I believe it has been customary in the past to operate a motor of small capacity, and by reason of that small capacity the expenses of maintenance have been increased very materially. There is only one other matter I would refer to, and that is if the gentleman has any figures as to the cost of painting or varnishing the cars, cleaning up and touching up the cars, I would like to get the figures for the labor.

Mr. Harrington: In reference to the first matter, the greater depreciation in using single-motor equipments, we have been using single-motor equipments practically up to date, with the exception of a few double-truck cars recently purchased. About one year ago we equipped one 18-ft. body with double equipments, and where we averaged a car in the house, say once in every ten days, with the single-motor equipment, that car has only been in the house three times in a year, and that for only petty repairs. On the strength of the record of that car, our board of directors has concluded to order double equipment for twelve of our cars as a starter. Our armature depreciation has been, in my judgment, tremendous and altogether out of reason. On a forty-car road we have one armature man busy all the time doing nothing else but looking after the armatures, and I think we will be able to put him on some other work in conjunction with the armature work as soon as we have more of these double equipments. Just the exact cost of depreciation on single equipments it is difficult to say, but we are sure we will cut it down with the double equipment.

In reference to the cost of painting, while I have not definite figures in my mind, I can give you a general run of the work. The contract price for taking the car into the house, burning the paint off, painting and varnishing the car on the outside throughout, and varnishing the inside, is $20. For ordinary touching up and varnishing outside, with paint already on, and one coat of varnish on the inside, the contract price for an 18-ft. car is $6. The cost of material is approximately the same as the labor.

Mr. Foster: Do you do the work by the week or by the hour?

Mr. Harrington: We pay the painters $2.50 and carpenters $2 a day for that class of work.

Mr. Reed, of Salt Lake City: How many coats of varnish do you contract to receive when the cars are revarnished?

Mr. Harrington: Our contract covers putting on the first coat and the rough stuff, rubbing down, putting on the second coat and rubbing that down, and putting on three coats of varnish afterward. There are really five distinct steps in the operation.

Mr. Connette: There is one element of saving in running single motors where they can be conveniently run, and that is in regard to the power used. In Nashville, Tenn., there is very little level ground; it is up hill and down hill everywhere. I tried an experiment in the running of a single motor, and found by test that it used about 35 per cent less power than with double equipments, but we could not use the single motor for lack of traction. Most of our roads have no loops at the end, and consequently the ends of the car are reversed, and when the motor was in front there were many places where it was quite difficult to get up with a single motor, on account of the lack of traction. When the motor was on the rear axle, of course that difficulty was not so great, but there is a saving in power by the use of a single motor. It strikes me that where single motors are used that fact would, to a large extent, limit the capacity of the car, or the size of the car, in proportion to the power of the motor used.

In Louisville, Ky., where they operate possibly 200 or 300 cars, it has been my observation that nearly all of them are run with one motor only. One S. R. G. motor is employed, but their cars are small, most of them having been old horse cars converted into electric cars, and the city being comparatively level, I understand they operate very satisfactorily.

Mr. Douglass, of Cleveland: It seems to me that this question of single and double-motor truck cars depends a good deal on the condition of the track. I represent the

"Big Consolidated" road of Cleveland, where we recently have had a little disturbance, and we have some bad track, as do most other cities. We have some old Johnson rail on chairs, and all that kind of thing, and have recently purchased 150 double-truck cars, modern cars in every respect. One motive in getting these cars was to keep up with the times and handle our people in the best way. Another reason was that we have some bad track, and by putting the double-truck cars on this track the cars would run smoothly over the track, which was almost impossible with the single-truck cars. The relative advantages of single and double-truck cars is a question of track to a great extent. I think single-truck cars of from 18 ft. to 24 ft. in length can be operated more easily and simply than double-truck cars, and I do not think we should discard the use of such cars if our track is in good condition. It strikes me that the question of the track is largely a factor in this matter.

When I went to the "Big Consolidated" Road on May 1, I found that contracts for the painting of the cars were in force there, and they were unsatisfactory. The company was paying 25 per cent more for painting, touching up, burning off and varnishing, as the different requirements called for, than it actually costs now by days' work, and we are getting fully as good work. Under the contract system, the men painted the window glass and daubed things generally. We get much more satisfactory work by the day, and I think we save 25 per cent. That will apply to painting and varnishing.

We have a contract for making armature coils and doing similar kinds of work, which is extremely satisfactorily. We have that contract still in force, and that is the only contract work we do. I have not seen fit to change that method of caring for this work.

Now, about trolley wheels. When I went to the Brooklyn Heights Road about five years ago, Mr. Vander Veer was there, but I did not have the pleasure of making his acquaintance. They were manufacturing their trolley wheels out of zinc, brass and copper. I have often wondered since why we did not put in a brass foundry to make the trolley wheels. We are buying castings in the rough, and turning them down half way and putting in the bushings. I wonder why we do not make these castings ourselves and scrap our old copper and brass at 15 cents a pound before paying such large prices for new wheels. I believe, however, that the Brooklyn Heights Company has discontinued that practice. I would be glad to hear Mr. Vander Veer's experience on that line.

Mr. Vander Veer: With regard to the brass foundry, while it commends itself to a large road, our experience was that our men made things out of brass that should have been made out of iron, and we shut down the foundry for a while. We started it up again a short time ago.

Mr. Douglass: Is it not economy to make your own wheels on a road of your size?

Mr. Vander Veer: Yes; it is profitable.

Mr. Douglass: A saving of 25 per cent to 30 per cent?

Mr. Vander Veer: Yes, fully that; but there is always a tendency to drift off into other things.

Mr. Douglass: I am surprised that more of us do not make our trolley wheels.

Mr. Beggs, of Milwaukee: The question of Mr. Douglass brings out many other points as to the cost of operating a road, and the question whether roads could profitably manufacture trolley wheels, like many other things in use on the road, would depend on what they are compelled to pay for them. I have a contract for trolley wheels at the present time, made according to a formula which on our lines seems to be the most advantageous, as to the proper degree of hardness of trolley wheels to give best results without wearing the wire, as we consider it preferable to wear the wheel, at 23 cents per pound; we have also a contract for converting the worn-out trolley wheels into new ones. I do not believe that any road can afford to put in a brass foundry and make its own trolley wheels if it can buy them at that price. We can get 16 cents for the old wheels.

Mr. Douglass: Is the price quoted the rough casting?

Mr. Beggs: That is the finished wheel; a wheel 5 ins. in diameter, which is somewhat larger than the wheels on many other lines. We believe in large wheels, because they run at less speed. Our trolley wheels weigh approximately nearly 3½ lbs. finished, and including the bushing, and I do not believe there is any road that can maintain a brass foundry profitably when it can buy wheels at that price. The argument so often made by municipalities that they can operate street railways and electric light plants and other public utilities at less than we, who are in the business, can, applies here. Many times the special foundries in connection with your road are not charged off where they should be charged; that has often been the case with the brass foundries and other appliances run in connection with a road, nothing is charged off for superintendence, for percentage of capital represented, and everything of that kind. When it touches that particular point I do not believe that any road which is in a position to make a proper contract for trolley wheels can begin to make them as advantageously as some manufacturer who has other things to make in connection with the trolley wheels. It depends very largely upon the contract price which the road is able to make for trolley wheels. In view of the increase in cost of material during the last twelve or fifteen months, I am paying now about 30 per cent more for trolley wheels than under a contract made eighteen months ago. In order to get a satisfactory price I made a contract for 5000 wheels to be delivered to us at the convenience of the shop turning them out, made according to our formula and pattern, and they can turn them out in between times in their shop. I know that I could not run a brass foundry and begin to turn these wheels out for what they cost us to-day under a 5000-wheel contract.

I would like to throw out a suggestion here, Mr. President, in connection with this matter of motors, particularly as my friend Douglass has just made a contract for a large number of double-truck cars. I would like to give him the benefit of our experience at Milwaukee in connection with the number of motors. I do not believe any road can judiciously run single motors. I have not believed so for the past ten years. The 35 per cent of power saved, which has been referred to here, I think is threefold paid for in greater cost of repairs to single motors and other portions of the car. I think the cheapest thing virtually that we put on an electric railroad is the power that moves the car; it costs less than almost anything else going into the car. Three and a half years ago we adopted a standard car on our lines—a double-truck car. We have steadily advanced upon that plan and improved that equipment, until we put on twenty-five cars this year, and we will put on about thirty-five new cars annually in order to keep up our equipment. They are double-truck cars and are standard. For three years we contented ourselves with two motors on these cars. We put on twenty-five cars this year, and have contracted now for thirty to be delivered in April next, on which we shall put four motors, a motor on each axle, as an element of economy and greater facility and to give the public good service. The traction is much better, and we can speed up a car more quickly, and when you take a city where you stop every block, every 200 ft. or 300 ft., it is an important item if you can

save a few seconds in making these stops, and in getting the cars in motion. You thereby advance the convenience of the public and reduce the number of cars necessary to make up a schedule on any given line. For that reason we have incurred considerable expense in the improvement of these cars. We put on ten cars eighteen months ago, each car having four motors, and we find that it costs less for the maintenance of a car with four motors than for the maintenance of a car with two motors. The actual cost of maintaining the equipment under the car is reduced, and the number of cars in the shop averages only 2 per cent—we seldom have to pull one of these cars into the shop. The motors are not overworked, we can get the car up to speed within a very few seconds, and if a car gets behind its time it has the reserve power to enable it to make speed, which is an important element in the economical running of a street railway. If you can take five minutes out in the length of a run it is a great saving. For instance, we run pretty long lines, few of them less than 7 miles or 8 miles from terminal to terminal. We make 200 stops possibly in that distance, and a second or two saved in each stop, in getting up speed on the car, means a considerable amount in the number of cars necessary to equip and maintain the schedule. We have experimented on this subject very carefully. We know, of course, on our four-motor equipment—speaking off-hand, without figures—it possibly requires 30 per cent more power than to run two-motor equipments to pull the same car, but we are moving at higher speeds, saving money in other matters, and giving much more satisfactory service to the public, and we are saving wear and tear on the equipment. The cheapest thing we have on the road is power.

Mr. Foster: What type of motor do you use?

Mr. Beggs: We adopted as standard the G. E.-1000 motor. We put one motor on each axle. We have several grades, none very severe, but we have no trouble from slippery rails or frost in winter, and with our four-motor equipment we never think whether the car is going to get over the line.

The number of flat wheels has been greatly reduced, and in every way the cost of maintenance on a four-motor equipment is 25 per cent less than on a two-motor equipment. One of the reasons for our adopting the four-motor equipment is that we can give better service to the public, make more regular time, and haul larger loads. Our cars are very heavy—almost as heavy as the cars on a steam railroad. Our cars have twenty-two double seats and seat forty-four passengers. We frequently have over 100 passengers on these cars on account of there being wide platforms, the car being 41 ft. over all. That is the car we have adopted as standard after experimenting for three years, both as to the amount of power consumed and the wear and tear on the cars and rails, and, while we are running more motors on our lines, I do not think the number of men in the armature department is one-half what it was three years ago.

Mr. Connette: I do not mean to advocate a single-motor equipment, but I do say this: that with small cars, where the streets are comparatively level and where the power of the motor is in proportion to the size of the car, single-motor equipments can be operated for less expense than double. I know by actual meter tests that an 18-ft. closed car body, with single truck and two motors, requires about 150 kw. hours per day, of 125 miles to 140 miles. The cost of power, of course, varies, but a fair average is one cent per kilowatt hour. Therefore, if you use 150 kw. hours per day for each car and save 33 1-3 per cent, the saving of power would be 50 cents per car per day, and where thirty cars are run it means $15 a day for power. From the experience I have had in maintenance I consider that it will not cost as much to maintain one motor, even with a little extra service, than it does to maintain two motors. We think that two motors, involving as they do, four fields and two armatures, with all the incidental connections, must cost more to maintain than one motor, even with extra service; but where in larger cities you have larger cars and higher speeds and heavier travel, then perhaps our judgment would change in favor of the double motors, because more effective and satisfactory service can be obtained with two motors on a car than with one, but so far as the element of expense is concerned, I believe it is more economical to operate one motor than two motors, where it can be done, and I believe that it is limited to the smaller places and to places where the streets are comparatively level.

Mr. Foster: I would ask Mr. Beggs one question, and that is the average speed made by the four-motor equipment cars, and also if he uses power brakes, and if so, what kind?

Mr. Beggs: We do not use power brakes on our city equipments. In fact, where we run local service with interurban cars equipped with air brakes we shut them off in the local service. We try to maintain a speed of 8½ miles over the whole system. Speed is certainly an important element to take into consideration, as stated by Mr. Connette. We maintain one of the longest headways of any city in the United States for a thickly populated city, and one of the elements is the large cars and the great regularity maintained in the time table, which in the city traffic is kept up as closely as on steam roads. Even on our lines where we stop every 300 ft. or 400 ft., we maintain an average of 8½ miles an hour, and on some lines 9 miles an hour and over. No car makes less than 160 miles to 170 miles daily, and on our interurban lines we make as high as 380 miles a day to a car, day in and day out.

Mr. Foster: What type of motor is used? Is it a different type?

Mr. Beggs: The same motor exactly. We have to take the conditions into consideration, as Mr. Connette says. We have a considerable number of interurban lines spreading out like the spokes of a wheel, and we are trying to standardize the equipment so that if we need to send cars out on any line they have the element of speed connected with them. These cars are equipped with the ratchet brake. On our high-speed interurban lines we make a day nineteen trips of 20 miles each with two cars, and have done it for eighteen months. On these lines we have air brakes and arc lights, which are absolutely indispensable to a high-speed interurban line.

Mr. Foster: What is the maximum rate of speed on the interurban line?

Mr. Beggs: I should say that on certain portions we reach a speed of nearly 50 miles an hour. The line runs between the city of Milwaukee and the city of Waukesha, and for 6 miles or seven miles within the city limits we provide local service. On our city lines we have high-ratio gear.

Mr. Foster: Is the road on a public highway or private right-of-way?

Mr. Beggs: The particular line to which I referred is on private right-of-way. We have one interurban line 35 miles in length on a public highway. We do not get that speed on that line, but hope to reconstruct it so as to be able to do so.

Mr. Lang, of Toledo: I want to touch upon two subjects that seem to be most directly before the convention this morning, and the first is with reference to the maintenance of a brass foundry. In Toledo we are operating a street railway and an electric light plant combined, and we maintain a brass foundry, and I take it that that is an in-

dorsement, at least from our point of view, of the wisdom of maintaining a brass foundry, that is, assuming that we are giving proper attention to the item of expense. We pay our brass foundry man $1.75 a day, and he is a good man. He spends his entire time in the brass foundry, and he takes every scrap of brass that we have and works it into every available place on the car, in the lighting plant and about the power-house where brass is used, and we are satisfied beyond any doubt that it is a most economical way to operate this part of a railroad. We cast our own trolley wheels. As I say, every brass fixture appertaining to the car is manufactured from our own furnace.

With respect to the double-car equipment, it depends, I think, very largely upon local grade conditions. We are operating two motors on each car, our standard being the No. 3 Westinghouse motor. We have a few G. E.-800 motors. A suggestion that I desire to make that may be of value to some of you is the fact that we have just entered upon a method of splicing two 16-ft. car bodies together. It has been a serious question with us what to do with four-wheel cars that have been in operation from eight to ten years, and following the same line of procedure that was adopted at Columbus about three years ago, we have just taken two 16-ft. car bodies and spliced them together and put them on double trucks. We have placed these cars upon one of our longest lines, where we have been maintaining a nine-minute headway for some two or three years, and found a necessity for increasing the accommodation. To avoid the necessity of running more cars we concluded to put these double truck cars upon that line, and have had them in service about sixty or ninety days. They look exactly like new cars. An expert could tell the difference, but the people who ride in them say: "What a magnificent car this is." They are pleased beyond measure with the new cars, and we think by that means that we are still going to maintain our nine-minute headway without complaint, because the cars seat more passengers and their speed is just as high as a 16-ft. car. It was argued that we would not be able to maintain our speed using two 25-h.p. motors, but in our city, where we have few grades, we find that we can maintain our speed just the same with our double-truck car as we did with our single 16-ft. car. As you can see, the former can earn a great deal more money. I think that where the situation of roads is similar to our own it will be found of great advantage to take some of these short cars that are nearly ready for retirement, and by putting in new sills and bracing them up properly, to utilize them for a long time.

Mr. Foster: Can you give us an idea of what it costs to reconstruct the two cars into one?

Mr. Lang: It costs in the neighborhood of $300 for labor and material entering into the reconstruction of the car body. The car has longitudinal seats.

Mr. Dimmock, of Council Bluffs: Our company took some 16-ft. car bodies that had been in service for between six and seven years, spliced them together and made a number of cars measuring 42 ft. over all, including vestibules. We have run them for five years, and, outside of painting, they have required no repairs to speak of since the day they were rebuilt. I think the splicing of these cars cost us in the neighborhood of $300 or $400; I have forgotten the exact amount. We find that the double-truck car is better for the service. It was claimed that we could not keep up our schedule on the same headway, after splicing these cars, and especially so after putting gates on them. We equipped these cars with gates, which are operated with a lever controlled by the motorman, and we find that the power consumed is somewhat greater than it was before the gates were put on, on account of the additional number of complete stops required to be made. Nevertheless, the car is giving better service and running on the same time-card as that of the 16-ft. car. The speed of the car in many places is as high as 30 miles an hour, and the repairs are not more than they are on another line, where 16-ft. cars only are used.

Mr. Beggs: I would like to ask whether the cost of splicing the two 16-ft. car bodies referred to includes the trucks?

Mr. Lang: No, sir.

Mr. Beggs: What kind of trucks do you put under them?

Mr. Dimmock: Double trucks.

Mr. Beggs: That is an important question, because we have canvassed that matter thoroughly, and finally determined that it is not economical to splice our old car bodies, for the reason that by the time the trucks are under the car, the cost of the car is fully half the cost of the best car that can be built, and after spending this money you still have an old car. As Mr. Lang has said local conditions have a great deal to do with the question. For instance, this summer, in our city on the lake, we had very little warm weather to require people to take pleasure rides in open cars. We ultimately intend to dispense with the open cars and get the equipment down to standard equipment to be run twelve months in the year. To-day we put cross-seats in our cars, and this requires greater width than with the longitudinal seats. Our cars are 8 ft. 6 ins. wide, giving two cross-seats with a good aisle, and about 33-in. cushions on the seat. We made a careful estimate of the cost of reconstructing the old car bodies, and we found that it would be one-half the cost of the most modern car, with 7-in. sills, and we did not consider it a matter of economy. We do not want any longitudinal seats on our line. Our patrons prefer our standard car, and with the window sash down it is virtually an open car for all intents and purposes. Our cars are ready to run any day during the year. The amount of money spent in splicing these car bodies does not begin to include all the expenses involved, and then you have nothing but second-hand equipment. I think you will all admit that when you take an old car body built for the lighter traffic of ten years ago, and endeavor to reconstruct that car, that it will only be a short time before the car begins to creak again at the joints.

Mr. Dimmock: We have run our cars five years without repairs, but in order to make our car as good as we thought it ought to be, we had a steel frame put around the bottom of it, with truss rods, which caused the car to stand all the racket of bad track, etc. I will admit one point, however, that if we were buying new cars we would prefer them lighter and with cross-seats. We have also spliced our 16-ft. open cars, and the difference in the two cars is that the closed car seats forty-four persons, while the open car seats seventy-five. Another feature was the track centers. Our track centers will not permit of a wide car, and this fact aided us in making a decision to splice the old cars. If the track centers had been wider we might have considered the purchase of new cars. We feel we are money in pocket by the splicing of the old cars, under the circumstances which exist in our city.

Mr. Foster: What is the depth of the flange on your wheels, Mr. Beggs?

Mr. Beggs: I think 1⅛ ins.

Mr. Foster: Do you run them over a girder rail or a T rail?

Mr. Beggs: Our standard road-bed construction is a T rail with granite headers and stretchers. We form a groove out of the granite, and if you came to the city of Milwaukee you would see the same effect as with a grooved rail without the gnawing. In the city limits every

foot of track is put down so as to admit paving in any way that the city wishes to do it. We use 6-in. T rail weighing 70 lbs. to the yard.

The President: Gentlemen, this is straying a little from the matter immediately before us, and encroaching on the subject of a future paper. This paper is on the subject of car equipment. I think we should be glad to continue the discussion of the subject directly in hand.

Mr. Dimmock: Before we get entirely away from the question of trolley wheels, I would ask if any of the gentlemen present has kept the mileage on the trolley wheels?

Mr. Beggs: We get about 8000 miles or 9000 miles from our trolley wheels. I know of roads that get as high as 17,000 miles. Our policy is to prefer to wear the wheel. Our wheel is made up of a composition of 86 per cent of copper, 8 per cent or 9 per cent of tin and 4 per cent or 5 per cent of zinc, and we get a composition which wears the wheel rather than the trolley wire. Our trolley wire is No. 0000 over our entire system. We get about 9000 miles from our trolley wheels, and do not want any more. It costs less to wear a trolley wheel than it does to wear a trolley wire. The cost of putting up the wire is as great as the wire itself. I know there are some certain roads that make a boast of the number of miles they get out of a trolley wheel. They used a steel wheel in Milwaukee three years ago and were grinding the trolley wire constantly.

The President: Is there any further discussion upon this subject? If not, I think we should proceed to the subject of "The Modern Street Railway Shop: Its Design, Machinery and Shop Practice." It is a subject that I am sure everyone here is anxious to talk about, and, in the unavoidable absence of Mr. Kilgour, who, we expected, would speak on this subject, I am in hopes that it may be started by Mr. Knox.

Mr. Knox, Chicago: I was only notified a couple of days ago that I was expected to participate in this discussion, and I have not given the matter any special thought. I was hoping a paper would be presented to the convention. I consider it one of the most important problems we have, where there are perhaps greater leaks than in the other things we talk more about. I have not been able to give the subject proper consideration, however, and must beg you to excuse me from going into it with greater detail.

The President: I hope we shall hear from some other gentlemen on this subject. If there is to be no discussion on this subject the Chair will announce the committee of five to make nominations for officers for the ensuing year and determine upon a location for the next meeting. I appoint for this committee H. C. Moore, Trenton, N. J.; E. C. Foster, Lynn, Mass.; E. G. Connette, Nashville, Tenn.; Robert McCulloch, Chicago, Ill., and A. E. Lang, of Toledo, Ohio. Invitations to the association to hold its next convention in any city should be presented to this committee, and any argument or inducement held out by any city should be laid before them. This does not, of course, in any way preclude the presentation of any argument at the time of the committee's report.

Secretary Penington then announced that luncheon would be served on the special train taking the delegates to the drainage canal. The meeting then adjourned.

THURSDAY'S SESSION

The president called the meeting to order at 10:35 A. M.

The secretary read a telegram from H. M Watson, of Buffalo, N. Y., regretting his inability to be in attendance at the meeting, owing to business engagements. The secretary also read an invitation from the Westinghouse Electric & Manufacturing Company to visit the power-house of the South Side Elevated Railroad, the privilege to do so having been granted by the railway company. A special train was arranged for to leave the office of the South Side Elevated Railroad Company at 2:30 P. M. on Friday. The secretary also announced that the delegates were requested to be in readiness at the Auditorium Annex at 1:45 P. M., to start on a tally-ho ride.

The President: The first paper to be read this morning has been prepared by Edward Butts, of the Metropolitan Street Railway Company, of Kansas City, Mo., and the title of the paper is: "The Construction and Maintenance of Street Railway Track."

Mr. Butts: The paper I am to read has been prepared on the basis of our investigations in Kansas City for the past five years. It is our conclusion that the track construction described in the paper is that best fitted for the conditions presented. [Mr. Butts then read the paper, which is published elsewhere.]

Mr. Foster, of Lynn: I have listened with a great deal of interest to the paper on the "Construction and Maintenance of Street Railway Tracks," so ably presented by Mr. Butts. It seems to me that he has covered the ground pretty well for drawing up specifications for the building of a first-class girder-rail track. I did not notice that he touched upon the construction of T-rail track. It is necessary to construct the tracks of our roads differently, according to the different localities. The city roads in all of the cities with which I am familiar require a much superior track than the roads located in suburban towns. I notice a reference in the paper to the girder rail being laid on blocks, the rail spiked to blocks and then surrounding that with concrete. I should say from my observation that there might possibly be a better method than that. I trust the gentleman will pardon me for so expressing myself, but it seems to me that it would be better policy, in laying girder rail on concrete, to omit the introduction of any wood, because with the passage of time this wood must decay, and when it does decay it will weaken the structure.

Mr. Holmes, of Kansas City: Mr. Butts should have explained that these blocks are used only for the purpose of alignment, and not to support the rail.

Mr. Foster: I did not so understand it; I understood the blocks were put in there for the purpose of maintaining the track. As I understand it now, they are put in there temporarily, simply to surface the track, and there is no use of going further on that line. I should think, however, that the concrete base under the rail was superior to any other method.

The subject of cross-ties is one which we meet in almost every section of the Eastern country, as over 90 per cent of the roads there are using cross-ties. The kind of a tie and the dimensions of the tie are two points in which I am interested. Some roads use a 5-in. x 7-in. tie, 6 ft. 6 ins. in length, placing them from 24 ins. to 30 ins. on centers. On a T rail, where you are going to operate at a high rate of speed, as many of the electric roads now anticipate doing, and many, in fact, are doing at the present time, it seems to me that we should use a tie of about the same dimensions as the ties used on steam railroads. We are at present constructing 5 miles of double track with the T rail. The ties are 6 ins. deep, 8 ft. long, and run up to 10 ins. in width, being practically a steam railroad tie. We are laying on this tie a 70-lb. American civil engineers' section of T rail, and are using one of the improved joints. In the construction of this track, which will be used by cars running 25 miles or more an hour, we believe we should adopt as near as possible the steam railroad construction. On some of the smaller and less important lines I do not think it is necessary to have so heavy a rail, although I am thoroughly of the opinion that money invested in a heavy rail and a very heavy cross-tie and a

track of the best construction possible is money wisely invested.

All our girder rails are laid on cross-ties 5 ins. x 6 ins. x 7 ft. in length. Some roads are using a tie 7 ft. long, and others use a tie 6½ ft. long. I think that in some cases a tie 6½ ft. in length is not sufficient. Where the street is concreted you get but a small bearing on the outside of the rail, and it seems to me that an additional 3 ins. on the outside of the rail, if you use a tie 7 ft. long, is very important. It adds very materially to the strength of the track and keeps it in surface and alignment. This subject is one that we might talk about for a long time, relating our experiences and giving our opinions. It is possible for a man to get up and tell theoretically what kind of a track should be built, but he must take into consideration the financial condition of the road to be operated. All of these things enter into the construction of the track—the question of how much money can be put into it. We all agree, I believe, that the first construction should be of the best, provided the finances admit of it.

The question of maintenance is also important, as important, perhaps, as construction, and with many it is a problem as to how best to repair an old track. We all remember very well that in the old horse-car days we used to operate over a rail weighing only 20 lbs. to the yard, spiked to a stringer and underneath that stringer was a little tie about 4 ins. x 5 ins. We then went from that rail up to the 25-lb. rail, the 40-lb., 45-lb. and 50-lb. rail, and then to the 60-lb. rail; all of these weights were made in a tram rail and about as many in the T rail. Then we commenced with the girder rail of 40 lbs., then 45 lbs., 50 lbs., 70 lbs., and now on most roads, where it is necessary to lay the girder rail, a 9-in. 90-lb. rail is being used. It is with these lighter rails to which I have referred that the problem comes in. We have some 45-lb. girder rail made in 1890, mounted in steel chairs on small ties, 4 ins. x 5 ins. x 6½ ft. in length, 3 ft. on centers, and that was thought to be a modern construction at that time. The road to which I refer is 6 miles in length, and was acquired by our company by purchase. The people who built it made a pretty thorough investigation at the time it was constructed, and thought they had secured the ideal construction for a road for electric operation. Time has shown that they were in error. Now the problem with us is how to utilize that rail to the best advantage. The lips of the steel chairs have become worn to such an extent that they do not hold the rail securely. We do not believe it wise to purchase new steel chairs, so we have been substituting the old-fashioned stringer for the chairs, knowing that we can obtain from six to seven years' life in the stringer, and thereby get six or seven years out of the rail. The head of the rail is worn but very little. I believe this plan to be economical under some conditions where the traffic is light. Of course, where the traffic requires a fifteen-minute service, and from that down to ten, twenty or thirty cars a minute, or as many as can be run on the track, of course the latest and most modern type of track construction is necessary.

Caring for the T rail is another subject for consideration. While a 35-lb. T rail may answer the purpose—some steam railroads are operating over a 35-lb. T rail—I believe it will not do so successfully on a cross-tie. It is very difficult to hold the joints even with any of the improved joint-plates, and there are some very excellent plates on the market.

The method of cast welding is another solution. I suppose this might be applied to some of the old track, and, in fact, it has been, but I have questioned the wisdom of applying it to the 26-lb. rail. Many of the rails laid on the roads in 1890, 1891 and 1892 were very soft and wore out very quickly. The trouble seemed to be due to a defect in the formula for mixing the metal and rolling the rails at that time. That, of course we realize, has been very materially improved, so that to-day we have a very high carbon rail. I believe that on many of these smaller roads this light rail can be used, perhaps, successfully and profitably, until the finances of the road will permit it to introduce a more modern and better construction. To my mind, the local conditions and the ability of the company to make the outlay are important factors in determining what is best for the property.

Mr. Hawken, of Camden, Maine: In New England the question of the railroad tie is a very important one. We have used what we call a hackmatack tie. We also use the cedar tie, the oak tie and the chestnut tie, and I would ask Mr. Foster what kind of a tie he has found to last longest and to give the best results?

Mr. Foster: In reply to the gentleman I would say that our experience has been that the chestnut tie gives the best results. We use many of the soft woods, such as cedar and hackmatack, but think that the best results have been obtained from the use of a chestnut tie.

Mr. Keegan, of Toronto: It seems to me this discussion raises a very important question as to the advisability of rigid construction on lines where there is heavy traffic. I have had occasion to construct some lines upon a concrete foundation where the traffic has not been excessively heavy. The results so far have been very favorable indeed, but it would be very interesting to learn from some cities, where they have adopted this rigid method of construction, whether any observations have been taken to determine if there is any yielding in the rail. I have had observations taken on other lines, and find that the give in the rail is very considerable. Of course, where there is a heavy travel this method of rigid construction has been adopted, but it is a question if it does not affect the rolling stock; and I should like to ask Mr. Butts if he has made any observations to determine whether there has been any give in the rail when heavy loads pass over it; also the style of cast-welded joint he has adopted? I take it that it is what is generally known as the Falk joint. I should also like to ask if any provision was made for contraction and expansion of the rails. I know that some companies do not make any such provision, but I understand that in some places a great many broken joints have been the result. I would also inquire what provision is made for contraction and expansion while the construction is proceeding on long lines. The action of the sun in hot weather upon these rails, if the rail is exposed, naturally would be rather disastrous.

Mr. Butts: We have operated a road for the past four years, as outlined in the paper, and there is no perceptible tremor, deflection or yielding of the rail. We have been constructing track on this system continuously every year from that time up to the present day, and we are still doing so. Any tremor would probably be caused only by the use of poor material or employing soft material too close to the rails. In regard to the cast-welded joint and the expansion and contraction of the rails, I would say that our method has been to put the concrete around the rails before the welded joint is put on. That holds the rail in place perfectly, and there is no displacement on straight lines, although we have had to do some little extra work on curves on account of cast-welded joints on the curves. This was because the joints were put in before the concrete had settled thoroughly in these places. In concreting the track we leave an aperture where the welded joint is to be placed. After the concrete has set a sufficient time we go along with the welding machine and cast-weld the joints. In that way we have not had any bad results.

Mr. Jones, of Memphis: I would like to hear from Mr. Butts or some other gentleman who has had experience with this rigid foundation for the track, as to how he arranges to put in that construction and operate his road on the regular service.

Mr. Holmes, of Kansas City: We use portable cross-overs, and cut out so many feet of the track, say 1000 ft., depending on the traffic on the line. The cars going in both directions use that one track for that distance. If the weather is warm the concrete will set in four or five days, but, of course, it is very slow work. It is sometimes possible to divert the travel from the track which is being rebuilt, and to put the cars on some parallel street.

Mr. Wason, of Cleveland: There are one or two points which have developed in the use of cast-welded joints that we have laid in Cleveland, which hardly encourages us to repeat the experience. We have had some experience with electrically welded joints of this character, but we have been unable to keep perfect alignment, both as to gage and surface. The track which we have put together with the twelve-bolt angle-plate has proven much more satisfactory than the cast-welded joint track. We have not used the foundation which Mr. Butts has described, but we have a very liberal supply of ties with very careful tamping. We are now using broken stone cement around and underneath the ties, allowing it to set and afterwards filling up underneath the rail. I do not think we shall use the cast-welded joint any longer, but depend entirely on the angle-plate with the twelve bolts to hold the track in line. It does not seem to me that it is possible to ignore the contraction and expansion of that amount of material, no matter if it is seven-eights covered in the ground and held in place in a measure by concrete or block pavement. The suburban work, it seems to me, cannot be made too well, and if you follow the lines laid down by steam railroad practice you surely will not lose money. If you cannot afford that construction, do not build the road.

Mr. MacGreggor, of Houston: Mr. Butts does not say anything of cast-welded construction in unpaved streets. I presume he has had some experience (I have had a little), but I do not know whether he has had any unfavorable results in using cast-welded tracks in streets not paved. The question of bonding is not mentioned in his paper, and I would like to know whether the tests for carrying the large currents without any bonding through the cast-welded rail have been satisfactory. Then there is another question, which perhaps hardly belongs to that paper, and that is the matter of the head of the rail, on which I would like some information. I have taken a fancy to what is known as the Trilby head of rail. I have not used any, because I have always ben able to use a T rail, but it is coming to that position with us that we will have to use something else to satisfy the municipal demand, and I would like to know from somebody who has used it if the Trilby rail is satisfactory for a girder rail. Another trouble we have had is that the large roads are setting the pace and the small roads are expected to come up to their standard. Yesterday the difference between the small roads and the large roads was exemplified in the use of four motors on a car. I can readily understand that a company having a large business can feel it to be a matter of small expense to use four motors, instead of one or two; but to a road with small business and fixed expenses it would be a disadvantage, and I think that if we could draw a distinction here between those roads which have all the business they can handle, and more, too, and those roads which have not the business, we will get a standard for each, and I think that is what we need.

Speaking of this rail question, the large roads have set a pace requiring a 9-in. rail. I have been using a 6-in. T rail. I wanted to get a girder rail to correspond with that 6-in. T rail, but the supply people cannot furnish it, except with a 4-in. base. I do not think anyone running an electric railroad desires to put down a 4-in. base-rail, but that is all I could buy—a 4-in. base with the old-style head. I want a wide base and a modern head to the rail, but they say that everything in this style is 9 ins. high. We have not any ballast down our way, and we try to get up near the top. Every mile of concrete that we lay costs us $1200 a mile, and we skim along because our pocketbook is thin and we want a standard to carry the light traffic we have. We earn from $10 to $25 a car day, and many of these large roads earn from $50 to $100 a car day. We want to get into the small road class, and have some discussion here which will apply to that class of roads.

As to the experience with ties, being close to the cypress swamps, we use cypress ties, which are creosoted. My experience has been that the lengthening out of the tie to from 7 ft. to 8 ft. does not benefit us. With the question of bonding is brought up another question of the experience, outside of the paved streets, with the cast-welded joints. I am putting in cast joints, but I have not yet the experience to enable me to express an opinion on the results. I would like to hear from those who have had experience along this line.

Mr. Heidelberg, of Chicago: I did not intend to say anything when I came here, but hearing the cast-welded joint discussed so much, I must say that our company was the second to employ this joint after it was introduced. St. Louis was the first city to try it, and we were the second, and in 1895 we started to put the cast-welded joint on our road. There has been some discussion here about the alignment and the level of the track. I will call your attention to some track that was laid only last week on Eighteenth Street, from Wabash Avenue to Indiana Avenue, and on Indiana Avenue, from Eighteenth Street to Thirty-ninth Street. We have 10 miles of this track on Halstead Street, from Archer Avenue to Sixty-ninth Street, done this summer, and I do not think that you will find one joint out of alignment or out of level. I can only tell you the experience of our road, as I never worked for any other railroad, and have been with this company for fifteen years. In the matter of ties, I believe that local conditions have a great deal to do with the life of a tie. I have made experiments, and find that the creosoted cedar or hemlock tie is the only tie to use in sand, whereas in a clay soil we have found white oak the only tie to use. We use a 5-in. x 8-in. x 7-ft. tie, chisel-point spike and side brace-plate, which we use extensively on our own road, and a great many other people have now adopted the brace-plate that we use.

As to the rails, we have tried all kinds. First we had the old flat rail, and from that we came to the first girder rail made, 42-lb. Johnson, and then 63-lb. Johnson. Then we went to the 70-lb. 6-in.; to the 77-lb. 7-in.; to the 85-lb. 7 3-16-in., and then we took up the improved 9-in. girder rail at 90 lbs to the yard. We laid a great deal of this latter rail, but it did not give satisfaction. The reason is that we have various kinds of pavements, such as macadam, cedar blocks, etc., and the rail was too high, it rocked too much on us. Another fault that we found with the 9-in. 90-lb. rail was that the web was too thin for the height. The extreme changes of weather here, in winter we sometimes get a warm rain in the morning and a hard, cold snow storm in the afternoon, were too much for these rails, and they would pull and break, because the metal was rolled out too thin. We would like to construct our roads as we wish, but the municipal conditions will not allow us to do so.

Some one spoke here of putting the concrete under the rails. We have none of this form of construction, but our cable lines are all laid in concrete, and we find that in from eleven to fifteen years the concrete rots out and crumbles. Our yokes and rails go down into it, and it becomes a trench, and every time a car goes over it it oscillates and goes down. When it does so you know what it means—the car is being pulled up hill all the time, and that means power.

Mr. Butts, in his paper, stated that he poured the metal for the cast-welded joints at a bright yellow heat. My instructions to my men are to pour no metal into a mould unless it is at a white heat. If it is not at a white heat they are to make a pig of it. The reason is that after sand blasting the joint and getting all the pits of the rail perfectly clean the metal must be very hot in order to flux and amalgamate to the rail. If you do not do that you are not sure of a bond. When you do that, and have a man watch and see that the metal is at a perfect heat, then your bond is sure, for we have made a great many tests, and have not found any defective electrical connection when this method is carried out. In the early part of the history of welded joints we were a little skeptical about the process, but on making test after test and becoming more thoroughly acquainted with this work we found that the extra bonds were useless and a waste of money.

As to the matter of maintenance, no one seems to have spoken of organization in maintenance. In the maintenance of railroad tracks it is very essential to have a thorough organization of all the men under you, so that you can get them together at any time. I can get all of the force in our track department together at one point inside of an hour. That is a point which everyone should study. Track work has been my study for years, and I believe in giving the men good tools and having them thoroughly organized. We have a track master and a section foreman. We have six sections on our road and nearly 40 miles of road in each section. The sections are not divided strictly according to length, but according to the attention that they require; that is, if there are many railroad crossings in one section we take some straight line off that section and put it on some other section. The employees for each section are summoned by one man, whom we term a caller. The telephone operator at the main office calls simply this one man in each section, a man who lives near to the barn, and that caller calls all the rest of the men and tells them where to go. These things are very essential, especially in the North, where a hard drifting snow with very cold weather may come upon one in thirty minutes.

In conclusion, I wish only to say that I have been trying for eight years to cure a certain thing, and that is a wavy rail. We have some rail here which is what we call a wavy rail—there is a depression in the rail about every 3 ins. I have taken that rail out and sent pieces to the best experts in America, but I have never got any satisfaction from them. I want to know if anyone can tell me what is the cause of the wavy rail.

Mr. Butts: In answering some of the questions I would say that I have not advocated in my paper anything less than a 6-in. rail. We have not experienced any breakage of welded joints, and we have welded not less than 3000. They do not break, because the heat is refracted off into the earth as fast as it enters the rail, so that there is an equilibrium throughout. I would like to inquire what depth of rail the gentleman has on his cable construction?

Mr. Heidelburg: We now have a rail 7 3-16 ins. in depth. Previously we had a 6-in. rail, with a foot and a round base.

Mr. Butts: The rails in cable construction are laid on yokes, spaced every 4½ ft. to 5½ ft., and are not imbedded in concrete, but are supported entirely by the yokes, and therefore the experience with concrete in cable railroads does not apply to the concrete trench construction, as we understand it. For instance, there is a vibration between these yokes that will wear out almost anything. It is not a rigid construction. We do not bond the rails where they are cast-welded. The welded joint has the full electrical capacity of the rail. Where we do not put on the welded joint we bond with a No. 0 bond. We have had no experience with cast-welded joints in unpaved streets, but I believe that the success of that problem depends entirely upon the amount of metal that is embedded in the earth, as compared with the amount of metal exposed to the sun. I do not see why, if it could be maintained imbedded in the earth, it would not be as successful as if it were imbedded in other material.

The President: We shall now call for the report of the nominating committee, of which Henry C. Moore is chairman.

Mr. Moore presented the following report:

CHICAGO, Oct. 19, 1899.

To the President and Members of the American Street Railway Association:

Gentlemen—The nominating committee respectfully reports that it recommends Kansas City, Mo., as the next place of meeting, and the following gentlemen for officers of the association for the ensuing year:

For President—John M. Roach, general manager, Chicago Union Traction Company, Chicago, Ill.

For First Vice-President—John A. Rigg, president, Union Traction Company, Reading, Pa.

For Second Vice-President—H. H. Vreeland, president, Metropolitan Street Railway Company, New York City.

For Third Vice-President—F. G. Jones, vice-president, Memphis Street Railway Company, Memphis, Tenn.

For Secretary and Treasurer—T. C. Penington, treasurer, Chicago City Railway Company, Chicago, Ill.

For Executive Committee—President, vice-presidents and C. S. Sergeant, second vice-president, Boston Elevated Railroad Company, Boston, Mass.

C. K. Durbin, general superintendent, Denver Consolidated Tramway Company, Denver, Col.

Nicholas S. Hill, Jr., general manager, Charleston Consolidated Street Railway & Electric Company, Charleston, S. C.

Charles W. Wason, president, Cleveland, Painesville & Eastern Railroad Company, Cleveland, Ohio.

John R. Graham, president, Quincy & Boston Street Railway Company, Quincy, Mass.

Respectfully submitted,
HENRY C. MOORE, Chairman.
E. C. CONNETTE,
ALBION E. LANG,
E. C. FOSTER.

Mr. Moore: The committee received invitations from three places—Cleveland, Kansas City and Charleston. We found ourselves in a very difficult position. We love you all equally well, but we had to make a decision. We have also received an invitation from the city of Milwaukee for the year 1901, and from the city of Toledo for the year 1902.

Mr. Harrington, of Camden: I move that the report of the committee be accepted and the secretary authorized to cast the vote of the association for the gentlemen nominated, and for the place of meeting next year. Carried.

President Sergeant appointed Mr. Dimmock and Mr. Connette as tellers to receive the vote.

The secretary duly cast the ballot for Kansas City as the place of meeting and for the election of officers as nominated by the committee.

The President: I am pleased to declare that the gentlemen nominated have been elected, and that Kansas City has been selected as the place for the next meeting. (Applause.)

Mr. Holmes: Gentlemen, I desire on behalf of Kansas City and the Metropolitan Street Railway Company, which I represent, to thank you all most sincerely, and especially

the committee, for this compliment. I will say that while you are with us in our city we will do everything we can to make your visit a pleasant and profitable one. (Applause.)

The President: We will now have the pleasure of listening to a paper by Ira A. McCormack, of Syracuse, N. Y., on "Train Service and Its Practical Application." This paper is published elsewhere in this issue.

The President: Gentlemen, we are to be congratulated on having so interesting a paper on a subject which I think has never been presented to us before. We are indebted to W. H. Holmes, of Kansas City, for the suggestion of this subject, and I think it is only fair to ask him to say a few words upon it.

Mr. Holmes: I do not know that I can add very much to what has been said already on this subject by Mr. McCormack, but I will touch on a few things here before we adjourn. This is hardly a time to grow reminiscent, but my connection with the street railroad business dates back twenty-two years. I well remember when Kansas City was visited by the grasshoppers, which swept everything before them. It was not then a question of how much it cost us per car mile or per kilowatt hour, but the questions which concerned us were what would be the average life of the street car mule, and whether corn would sell at $1.50 per bushel. I am glad to say that we have grown from a little city whose street car needs could be filled with five cars to a large city carrying 50,000,000 people each year on the street cars, and with every indication of a continued growth. In this connection it seems to me that the employment of men is one of the important things to be considered, and I think it is pertinent. We have adopted a plan of setting aside a portion of one day in each week, which is Monday morning from 9 o'clock to 12 o'clock, to receive applications for employment, and at that time we generally call in some of the division superintendents to look the men over as they pass through the office. After selecting what men we need, they are required to make out an application, stating where they have worked and giving us such references as they are able to give. We have found that to be the best way of handling the matter, and we have been able to get very good men. I think this is a very essential thing in the street railway business, as Mr. Vreeland very happily said. The treatment and handling of the men is a very vital thing in the management of street railroads. I think it is possible to have your men like you and respect you at the same time. I have arranged this winter to give my men, the motormen, especially, a course of lectures, and have arranged with Professor Black, one of the best lecturers in the West, to come to Kansas City and deliver to our men a lecture on the practical application of electricity, at least every two weeks during the winter months. Our company will carry the matter as far as the men want to go. If they want to take a course in electricity, we shall be glad to see them do it. My opinion about the train service is that we are merchants, and we are selling rides, and we should use great care in the selection of the men, as the company is judged almost entirely by its employees. The public seldom comes in contact with the president or manager, and I think it is of more importance than anything else to use great care in the selection of men. We have followed the policy of promoting men from the ranks. We think that it is best to select married men, if we can find them. Many young married men come to our city to study the professions. They become dentists and doctors and lawyers, and often take up street car work for three or four years, until they complete their education.

The President: There is one street railroad in the United States that has the most difficult problems to deal with of any road in the country. That company, fortunately, is represented here, and I think that we ought to have a few words from Mr. Vreeland, of New York City, on this subject.

Mr. Vreeland: Any information that I could give the association with reference to this important subject presented by Mr. McCormack would hardly be available with the work on most street railroads. The work that we have in New York City, the greater part of the twenty-four hours, is to see how many cars we can run on the lineal feet of track which we have, consistent with the right-angle crossings at various points. Right-angle crossings and terminals govern our headway more than anything else on the greater part of the system. No doubt some of you gentlemen noticed some remarks I made, which I think were copied from the railroad papers, to show the magnitude of our proposition. The steam railroads of the United States last year handling 560,000,000 passengers, approximately, within the borders of the United States. We moved last year 265,000,000 cash passengers and 90,000,000 of transfer passengers, or a total movement of nearly the total of the whole of the steam railroads of the United States. (Great applause.) By these figures of comparison you will see, as Mr. McGregor said some time ago, you will have to make a separation of this proposition, and we will have to put our worthy president, Mr. McCormack, Mr. Holmes and a few of us in one class, and talk on these matters among ourselves, because these conditions do not obtain very largely in other systems.

I might say, by the way of following the lines as suggested by Mr. McCormack, that our system is handled with reference to time tables and the method of regulating time tables and making time tables, on the same general plan, as Mr. McCormack has suggested, and on the lines which we have frequently talked over together. The essential thing in arranging traffic, irrespective of its volume, is a study of conditions. The division superintendent and the general foreman, with the amount of detailed business that they have devolving upon them, are not the men who can make a time table. I made all the time tables for one of the largest steam railways in this country for five years, and I would not attempt to make a time table for one of our lines in New York. A man must give his time and attention to the local question surrounding the problem. An expert comes to lay out a prospective railroad, and his ideas of what the volume of business, of what that property is to get, are based upon a complete and thorough study of the characteristics of the particular section of the country and its people. The same study must be made with reference to the daily requirements of the street car lines in car mileage and the distribution of the same. To show how essential this is, I will say that I had a conversation some time ago with a superintendent who had operated a very large line for twenty years. I said to him one day: "What are the heavy hours of traffic on your line? How are you distributing the car service?" He said: "During the commission hours we run a large service, and then we reduce the service, and put it on again in the commission hours in the afternoon." I said to him: "Do you know that during the middle of the day you have the heaviest hours of traffic on your line?" He claimed that it was not so, and I told him that I would prove it to him by figures. I had a man take it up, and I actually showed that superintendent, who made a time table to regulate this running time, and took off cars during the middle of the day, that more people were moved per mile of track between 12 and 2 o'clock than during any other two hours of the day, and that during this time his cars were stored in the house. He used his best judgment, predicated upon some years of experience, by giving

the fullest service in the early morning and in the evening, but did not give it at the time it was actually most required.

We do not allow a division superintendent, a general foreman nor a chief inspector to make time tables for our system. A study of the situation is made thoroughly, as indicated by Mr. McCormack, and then the time table is laid out by a man who is employed for that purpose and followed up in that way. I shall take your time a little longer, and give you an illustration to show how pertinent these questions are. East and west of Central Park, in New York—of course, I can only bring illustrations from the line with which I am actively engaged—there are three lines on each side of the town. The arrangement of the car service on these lines was almost equal during the early hours of the day, but a close study of the people and their habits brought us to the conclusion that on the east side of the town the large car service should be started at 6 o'clock in the morning, and the large car service on the west side of the town should be started at 8:30 o'clock in the morning. We were previously running very nearly the same service on both sides of the town, and the change meant, of course, the saving of a great deal of money.

On the question of the average of speed, etc., we have to study these factors very closely to keep these things moving. We found it was impossible, even on short distances, to keep up the voltage of our lines during the hours of heavy loads, and we had to put in 4000-h.p. capacity storage battery plants, which are automatic in their action, to keep the voltage up, so we could do our business. For a long time there was a question of what affected the time tables. We sent out men to take measurements, and it was determined that it was not the fault of the motormen, althought at first they were blamed for it. They would have a car full of passengers, and the voltage was down to 400 or 450. By the increase of power obtained through the use of the storage battery plants we keep a uniform voltage of approximately 550 volts and meet the condition in that way.

The question of efficiency of employees, questions of that character are all pertinent to be discussed in this connection.

I think that traffic diagrams are the most important things for a man to have in connection with the operation of a street railroad. We have traffic diagrams taken at least once in every two weeks of every division of our system for the twenty-four hours—passengers against hours, similar to the one furnished by Mr. McCormack, and a copy of that is furnished to the general foreman or inspectors on the line, as well as the man who makes the time tables. Our diagrams go into the volume of business, showing the number of passengers carried per hour in each direction on every line of the system, in the twenty-four hours; thus, between 9 and 10 o'clock 4000 passengers went south, and from 9 to 10 o'clock 3000 passengers went north over the system. It is impossible to get any system of accurate inspection that will show where these people get on and off, without supplementing this work by the system which Mr. McCormack indicated, of special inspectors at certain points. I can say, heartily agreeing with the paper of Mr. McCormack, that it is very valuable for all of us to consider in connection with our work and that it would be utterly impossible for us to do the business we do in New York City, running the number of cars and handling the number of people we do every twenty-four hours, without making this one of the very important studies of our transportation department.

Mr. McCormack: I will ask Mr. Vreeland whether, in making a diagram of this kind, he shows the up and down trips in parallel, as I have? In my diagram the upper line shows the down trip and the lower line shows the up trip. You can see the traffic is uniform there from 5 to 8, and then on Sunday we show the traffic curve up and down by different lines.

Mr. Vreeland: It is our practice to sub-divide the blueprint sheets, using the upper half for the twenty-four hours south bound and the lower half for the twenty-four hours north bound. We worked on the system that Mr. McCormack has laid out there, but I do not consider it as valuable for the regular operation as it might be for this purpose here, and the fact that you put these charts of traffic in the hands of men who must take them in at a glance. They are not time table men, but practical operating men, who are going to criticise the time table, and you must have it so that it is a graphic illustration of the idea you want to convey. By interlacing your lines you throw it out. We show a clean sheet of south-bound and north-bound business on the same sheet, the two peaks coming together towards one another and practically making it the same, although they are distinct in their location on the chart.

The President: We want to get both sides of this subject covered, the small roads as well as the large ones.

Mr. Heidelburg: I am interested in the question of train service, and there is one question I would like to ask: The greatest trouble to-day in our train service in Chicago is something we do not seem to be able to cope with, although we have tried in very way, and that is the trading of transfer tickets at transfer points. I understand that in New York City they have had this matter before the State courts, and I would like to hear what they did with it from Mr. Vreeland. The situation here is that anyone riding over a line in Chicago will find at a transfer point a boy who will transfer you. The boys get the transfer tickets and sell them, and another passenger will ride on the original nickel paid the company.

Mr. Vreeland: I fully appreciate the difficulty under which the transfer business is done in Chicago, because in walking up-town the other day I stepped into a drug store to buy a cigar, and when I was going out the clerk said: "Are you going to take the cars, if so, here is a transfer." The transfer went with the cigar. The history of this thing in New York is a long matter of detail, too long to bring before the association at the present time, and I would suggest for the information of the gentleman that this subject was very thoroughly discussed, not only by our attorney, but by the men who are the head of our transfer business, together with the gentlemen who handle the transfer system of the Brooklyn Heights Railroad, which is as intricate as ours, at the convention of the New York State Street Railway Association held last month at Ithaca. It is fully given in the report published in the Weekly News Edition of the STREET RAILWAY JOURNAL for Sept. 16, and while I would be glad to give the information now, I appreciate the fact that it would be altogether too long to take up the time of the convention to do it. The answer of our attorney to a similar question propounded by some one with reference to the effect of that law was very full.

Mr. Dimmock: I would ask Mr. Vreeland what laws in the State of New York, if any, govern the crowding of the platform, and what the rules of the company are pertaining to the passengers crowding the rear platform of the car?

Mr. Vreeland: There are no regulations on this matter, except the regulation of the Board of Railroad Commissioners that passengers shall not be allowed on the front platform with the motorman of either open or closed cars. We did not follow it and a law was introduced to compel us to close the front gate and also keep passengers off the front platform. I went to Albany, and made an argument

against the proposed law, stating that the railroad company had absolutely no interest in it; that the law would not regulate the railroad company, but would regulate the public, and that if it was put into effect the practical effect would be that the public would be told that so many thousand of them must not go home until 9 o'clock at night, and they would at any rate have to delay their dinner. I suggested an amendment to the law which would cover the situation thoroughly, and that was a law compelling half of the passengers who desired to go north to turn around and go south, so that the carrying capacity of the cars would be adequate.

Mr. Dimmock: Have you not some law in regard to the crowding of the rear platform, so as to make it inconvenient for other passengers to get into the car.

Mr. Vreeland: There is no regulation, either municipal or State, on that question. We have, as you probably all know, the double door in New York City, which opens practically the full width of the rear platform, and we insist that our conductor shall not allow passengers to stand on the platform between the door and the side on which passengers are getting on, but that is not followed out very carefully. It is more a question of inches of capacity per foot on the car. I want to say, to show you how peculiarly we are situated in that respect, that the Board of Railroad Commissioners, with their inspector, came down last winter and looked that situation over thoroughly with reference to our Fourth and Madison Avenue line, and they said after their inspection: "We have nothing to recommend, and we do not see what you can do unless we say the people shall not ride. You are running as many cars as you can, and running them to the fullest limit during rush hours. You are running with regularity and dispatch, and doing everything you can to handle the people, and we must place ourselves in the position, not of saying to you what you shall do, but saying to the public what they shall do;" and, of course, in their own interest, they do not care to tell the public what it shall do.

Secretary Penington then read a resolution of thanks passed by the supply men to Ira A. McCormack for recommending to the executive committee resolutions for setting aside one day for the express purpose of inspecting the exhibits.

The secretary then read a telegram from D. B. Dyer, regretting his inability to attend the meeting.

Mr. Lang: Mr. President, I desire to offer this resolution:

Resolved, That the thanks of the American Street Railway Association be, and they are hereby tendered, to the several passenger associations, for having so kindly granted reduced rates to the members of this association and their friends who are in attendance at this meeting. Carried.

The President: It has been customary heretofore, as you know, to install the new officers on the forenoon of the last day of the convention, the banquet being held the night before. In consequence, the new officers have been installed in the presence of only a few members. The committee decided this year that it would be an interesting feature of the banquet to have the newly-elected officers installed at that time, and this will be done. When we now adjourn, therefore, we shall not adjourn until next year, but to be called to order at the banquet to-morrow night.

Mr. Vreeland: Before we adjourn I wish to be permitted to say a word. I regret that my engagements will compel me to return to New York this afternoon, and I desire to say that this is the first opportunity I have had since I have been connected with the street railroad business of attending a convention of this association. It has been exceedingly enjoyable to me, and I have made a good many friends here, I think, by the expressions they have given me since I have been here. I have certainly been very much benefited by these proceedings, and, although Kansas City is a long way from New York, if I should happen to be in this country next fall—which I do not expect to be—I shall certainly call on Mr. Holmes, as a result of my visit here.

The meeting then adjourned.

The Banquet

It is well within bounds to say that the banquet on Friday night was one of the two or three within the remembrance of the oldest convention habitué which was without a flaw from beginning to end. It was held in the banquet hall of the Auditorium, which was beautifully decorated for the occasion, and the scene was a picture of light and color which has rarely been equaled at any previous banquet. The menu was good in itself, was served *hot* by skillful waiters, and was not too long drawn out to be tiresome. The menu cards were beautifully engraved with appropriate designs. The speeches were short, crisp and well handled, and the entire function was over at 11 o'clock, giving another hour for social chat in the parlors thereafter. Altogether, the banquet committee, the Auditorium management and the speakers, are to be heartily congratulated on the skill with which this more or less difficult gastronomical and oratorical combination was this year carried out.

A much appreciated courtesy at the banquet was the presentation to each lady present of a beautiful little basket of flowers, "with the compliments of the Christensen Engineering Company."

At the table of honor sat the retiring president, C. S. Sergeant, of Boston; the president-elect, John M. Roach and Mrs. Roach; Past President Albion E. Lang, of Toledo, and Mrs. Lang; President J. F. Calderwood, of the Street Railway Accountants' Association, and Mrs. Calderwood; Past President Robert McCulloch, now of Chicago, and Mrs. McCulloch; Mr. and Mrs. George A. Yuille; President-elect C. N. Duffy, of the Accountants' Association, and Mrs. Duffy; Hon. W. J. Hynes and Hon. W. E. Mason.

President Sergeant acted as toast-master, introducing the principal speakers in a very happy manner, without committing the grave mistake so often found at similar functions of "taking the wind out of the sails" of those who were to respond to the toasts. Mr. Sergeant's odd conceit of the American Street Railway Association banquet of the future as one in which, instead of the brilliant company now annually assembled, would appear but two jaded, careworn men meeting together, one representing all the street railways of the country in combination, the other, a trust of all the manufacturers, excited great laughter, and he further summarized the present situation by saying: "No longer does the representative of the supply company sit in the ante-room of the railway manager waiting for an audience, meanwhile, perhaps, casting his eyes upon some such notice as this: 'The purchasing agent will see persons having articles to sell on alternate Tuesdays, from 2 to 3 A. M. On the contrary, the offices of the rolling mills and car factories are filled with dignified directors of the street railway companies, soliciting the high privilege of placing orders for delivery (not guaranteed) in 1910."

Senator William E. Mason was the first speaker at the banquet, and his subject was "Chicago." It was full of wit and humor, with a serious undertone, however, which gave for dignity. Senator Mason was followed by James W. Duncan, who responded to the toast "Illinois," a name

which, he said, represented a territorial area so nearly the same as that described by the previous toast of "Chicago," as to leave little ground to stand on for one who followed "Chicago" with "Illinois." The pride of the State of Illinois in its distinguished citizens—Abraham Lincoln, U. S. Grant and John A. Logan—was eloquently voiced by Mr. Duncan, as were also the physical and commercial features which have given her so prominent a place in the American sisterhood of States.

The toastmaster next introduced J. H. Stedman, of Rochester, as the man who had the temerity to undertake to designate and identify the lady passenger by punching her picture upon the margin of a transfer—an undertaking which signally failed, because of the gallantry of the conductors in punching all ladies as "young." Retiring President Calderwood, of the Accountants' Association, was next called upon, and he read an original poem on the subject of "Grease." The final speech was made by W. J. Hynes.

At the conclusion of the regular speeches, President Sergeant, with a few graceful words, delivered his gavel, the emblem of presidential authority, to President-elect Roach, who accepted it, together with the duties and responsibilities of the presidency, in a little speech, in which he expressed the hope that in his term of office he might be able to serve the association and street railway interests as well as Mr. Sergeant had done.

Following Mr. Roach's installation as president *de facto*, in charge of the festivities, Third Vice-President-elect F. E. Jones, of the Memphis Street Railway Company, and Secretary Penington were called upon for speeches, after which adjournment was taken to the parlors for a final hour of social enjoyment.

The Entertainments

On Wednesday afternoon a special train arranged for by the entertainment committee conveyed nearly 500 of the convention attendants to Lockport, Ill., the terminus of the main drainage canal of the sanitary district of Chicago, and at several points on the outward journey the train was stopped to permit inspection of this, Chicago's largest and most magnificent engineering work. It is probable that the immensity of this achievement could be realized by but few, if any, of the party, partly through lack of knowledge of the conditions which make such a work necessary, and partly because there is little in the neighborhood of the canal by which to gage its really enormous size. Figures also are of little value at such a time, but when it is stated that the necessary excavations involved in the entire work will be about equivalent to the removal of a layer about 3 ft. deep from the entire surface of Manhattan Island south of 125th Street, and that the entire cost of the work is estimated to be between $40,000,000 and $50,000,000, it will be seen how courageous is Chicago's spirit in grappling with so tremendous an undertaking. While the present plans do not involve, as some suppose, the construction of a ship canal from the lakes to the Mississippi River, it is true that there will be a continuous waterway which may eventually be developed into a ship canal.

Perhaps the greatest of the industrial enterprises of Chicago is the slaughtering of animals and the preparation of food products. This is one of the most highly organized industries to be found in the world, the division of labor and the introduction of labor-saving machinery being carried to their highest development. It was natural, therefore, that a visit to the famous Union Stock Yards of Chicago should be on the programme prepared by the committee on entertainment, and this excursion took place on Thursday afternoon. It had been intended to allow the attendants a liberty of choice between the stock yards and a tally-ho excursion through Jackson Park, but the weather was so raw and unpleasant that a change in programme was made, by which those who chose to do so rode to the stock yards in the tally-hos and returned through Jackson Park, the others going by trolley cars. The stock yards made a great impression upon the delegates, because of the wonderful system of handling the business seen there and the perfect cleanliness of all the processes.

On Friday, carriage parties to the principal stores, the Art Institute and Lincoln Park, were made up for the ladies in attendance, and the merchants of Chicago, particularly such concerns as Marshall, Field & Company, who own the greatest dry-goods establishment in the world, were doubtless the richer by many thousand dollars for this feature of the programme.

On Friday afternoon also a special excursion to the power station of the South Side Elevated Railway Company was made, upon invitation, and under the charge of the Westinghouse Electric & Manufacturing Company. A special train, kindly furnished by the South Side Company, left its office at 2:30 P. M., and about 100 were in the party. The station is equipped with four 800-kw. Westinghouse generators and two new 1500 Westinghouse generators are being erected at the south end of the station. Other apparatus represented in the station were the boilers of the Babcock & Wilcox Company, the economizers of the Green Fuel Economizer Company, the engines of the Edward P. Allis Company, the auxiliary steam apparatus of the Wheeler Condenser & Engineering Company, and S. J. McLeod.

The reception given in the Auditorium parlors on Tuesday evening by the entertainment committee and many ladies of Chicago was a *conversazione*, enlivened by music and refreshments, but with little dancing. Its object was to place the delegates and their Chicago friends on an immediate social footing, as well as to renew old convention friendships of many years' standing. Chicago's hospitality proved very warm and cordial, indeed. The reception was wound up by an impromptu concert, in which the Auditorium piano and several score of voices—soprano, alto, tenor and bass—took part, the soprano and alto gradually dropping out as evening passed into morning, until at length was left only the hoarse croakings of an occasional *basso profundo* reverberating from the marble walls of the Auditorium subway, and finally losing itself in the Turkish room or in long-neglected chambers.

Several private dinner parties at the Chicago clubs and in the hotels formed enjoyable features of the convention, and the absence of an iron-bound, rock-ribbed programme of entertainment made these special gatherings possible and most enjoyable. Right here, the action of the local entertainment committee in laying out its programme of social functions ought to be especially commended, in that so large latitude of choice was left to those in attendance at the conventions in the matter of entertainment features, particularly in the evenings. Wednesday evening, for example, was entirely free, while on Thursday evening those who cared to do so were privileged to make up theater parties to see "His Excellency the Governor," for which nearly the entire house had been secured by the entertainment committee for delegates and their friends. Many of those who attend the conventions have friends in the convention cities, for seeing whom they wish to reserve time, and where the entertainment is practically a "continuous performance" it is difficult to break away, unless, as in this case, optional features are introduced on one or more evenings.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

The two street railway conventions just held in Chicago cannot fail to materially strengthen both organizations, the American Street Railway Association and the Street Railway Accountants' Association of America. The business of both conventions was admirably managed by their officers and executive committees, so that there was not a dull moment from the time of arriving in Chicago till that of leaving. The sessions commenced promptly at the hour specified in the programme, and the meeting rooms were at all times crowded with delegates, instead of being neglected in favor of the exhibits or other attractive features, as has frequently been the case in times past. The greater interest on the part of delegates to the larger convention (the meetings of the Accountants' Association have always been well attended) was due to two reasons. The first paper on the programme to be read on Tuesday was one in which all were interested, both because of the prominence of its author, Mr. Yerkes, and the importance of his subject. The hall was crowded, therefore, during the reading of this paper and in the following discussion thereof by some of the ablest men in the industry, and this first meeting "set the pace" for the entire convention. The second reason was the wise determination by the executive committee, at the instance of Mr. McCormack, to leave one day, Friday, free for the inspection of exhibits, and at the same time to make certain that all or nearly all the delegates remained in town by placing the annual banquet on the evening of that day, instad of on Thursday, as has usually been done in the past. The results of this change of plan were most happy, and quite surely mean its adoption as a regular feature of future conventions, for it not only secured for the convention meetings themselves a larger attendance, as has just been stated, but opinion is practically unanimous that more actual business has been done at this convention than at any previous one in the history of the association. The delegates and "supply men" were able to get together without difficulty to close contracts, and a number of very large orders were placed for all kinds of material and supplies. This is decidedly as it should be, for such a meeting place as is afforded by these conventions ought to be a great convenience to both purchaser and seller.

* * * * *

Although the exhibit hall in Chicago was much smaller than that in Boston last year, and many of those who wished to make exhibits had to be denied space at the last, while the applications of all, or nearly all, were cut down almost 50 per cent, yet the exhibit seemed practically as complete as in previous years, and was well arranged for business purposes. All in all, the number of exhibitors was but little smaller than last year, while the amount of space taken was slightly less than 25,000 sq. ft., as against 33,000 sq. ft. last year. The committee on exhibits, of which James R. Chapman was chairman, certainly deserved credit for the remarkable success which it achieved in transforming Tattersall's, which is, in reality, an ugly and unpleasant building, into one which was almost a "bower of beauty," with its flag and streamer decorations, its complete arc and incandescent lighting service and its variety of exhibits. There is nothing but praise also for the care given by this committee to the interests of exhibitors. Everything worked smoothly and well, the transportation facilities were good, and on Tuesday morning all the exhibits were practically in place, ready for inspection, something which is not always, by any means, accomplished at conventions. At a meeting of supply men, held in Convention Hall, Oct. 19, with Elmer P. Morris chairman, and H. C. Evans secretary, resolutions were passed commending the action of Ira A. McCormack, of the executive committee, for recommending and having adopted the resolution, setting aside one day for the express purpose of inspecting the exhibits. At this meeting a vote of thanks was also extended to the association for its courteous treatment of the supply men.

* * * * *

The meetings of the Accountants' Association were, as has always been the case, businesslike and valuable to a

degree. This association has, in its two years of life, accomplished more than could possibly have been expected of it, and the high tribute to its work in standardizing street railway accounts recently paid by the committee on standardization of the National Association of Railway Commissioners, is most surely well deserved.

* * * * *

It is perfectly true, however, as Mr. Kittredge remarks in another column, that the Street Railway Accountants' Association is only on the threshold of its work. What has been accomplished so far, while most important and valuable, is still little more than the standardizing of a form of statement, not the development of a complete economical accounting system. We believe firmly that nine-tenths of our street railway companies are employing far too large a force in their accounting departments—that they are multiplying work—and that they are not in touch with modern commercial methods and labor-saving devices. When the largest street railway company in this country (gaged by gross earnings) is able to handle from $12,000,000 to $15,000,000 of money per annum in receipts and expenditures, and $5,000,000 to $10,000,000 more on construction account with but seven men in its auditor's department and two or three in its treasurer's, there would seem to be little reason for much smaller companies having the force of men which they now employ. We shall have more to say about the organization of accounting departments in the coming year, but meanwhile we urge our street railway friends to most carefully investigate accounting practice in the best models, and particularly to study the mechanical labor-saving appliances of modern accounting as exhibited, for example, in the great department stores or in some few of the street railways which have so far adopted them.

* * * * *

The new officers of both associations are worthy of their posts and of the traditions of the associations. President-elect John M. Roach has been connected with street railways for more than twenty-seven years in important positions of responsibility, and has always been a warm friend of the association. As he was chiefly responsible for bringing the convention to Chicago this year, and as he has done more than any other one man to make the visit the complete success which it certainly has been, he was the logical candidate, and had no competitor. First Vice-President John A. Rigg, of Reading, is at the head of several important Eastern properties recently brought together for the purpose of effecting operating economies, and is a man of the highest personal character and reputation. Second Vice-President H. H. Vreeland, although but six years in the street railway field, is generally recognized as one of the wisest and most successful managers in the country, possessing as he does in a high degree financial acumen, organizing ability and a knowledge of the influences that move men's minds, together with a broad, kindly and entirely genuine sympathy with the labor which he controls, and which is, to a man, enthusiastically devoted to him. Third Vice-President F. G. Jones, of the Memphis Street Railway Company, is one of the most prominent men in his section of the country, and C. K. Durbin, of Denver, Charles W. Wason, of Cleveland, John R. Graham, of Quincy, and Nicholas S. Hill, Jr., of Charleston, will add strength to the executive committee. Mr. Hill won a host of friends in this convention by his brilliant, aggressive and persistent campaign in behalf of Charleston as a meeting place for the convention next year, and while, for various reasons, he failed in this, his first effort to extend the hospitalities of Charleston to the association, the general feeling is that another year he will be more successful, if he still desires to entertain the convention. Finally, the association is fortunate in retaining for the new executive committee the services and experience of the retiring president, Mr. Sergeant—one of the best presidents who have ever occupied the chair.

* * * * *

The election of C. N. Duffy as president and W. F. Ham as first vice-president of the Accountants' Association is a natural and fitting result of the magnificent work which they have done as members of the committee on standardization, and of their devotion to the interests of the association. They have been always generous of both time and money in furthering the interests of the association, and, both being men of indefatigable energy and acute and intelligent thinkers, it is not surprising that the work of this important committee should have called forth the almost enthusiastic expressions of approval from the committee of the Association of Railroad Commissioners, quoted in the last report. W. G. Ross, of Montreal, the second vice-president, has always been prominent in the councils of the association. It would be impossible to name a man who could and would fulfil the duties of secretary and treasurer with greater care, patience and courteous attention to every inquiry than Mr. Brockway, and the amount of work which he has accomplished during the past two years is little short of marvelous. The department of blanks and forms, which he has created, is admirably conceived, and will be of such benefit to those who are desirous of improving their system of accounting that a trip to Toledo from any part of the United States is fully worth while, though by the system of correspondence which Mr. Brockway has instituted, such a trip is not always necessary. The Street Railway Accountants' Association of America has every reason to be proud of the fine lists of officers and executive committees who have been in charge of its affairs since the beginning.

* * * * *

In deciding upon Kansas City as the meeting place for the convention of 1900, the association has departed somewhat from precedent, in that two Western cities have been chosen in consecutive years, but this action has not been taken without good reason. While it is true that over 80 per cent of the street railway mileage of the country lies east of the Mississippi River, there should be at least an occasional meeting held in the further West, and we believe that Denver, or even San Francisco, would be popular, on many accounts, as convention meeting places, and that so many vacations would be arranged to take in the necessary transcontinental trip at convention time that the attendance would be little smaller than in the Eastern cities. Kansas City is certainly not too far west to attract practically all the Eastern delegates, while it is sufficiently far to perhaps bring into the association and to the convention many of the extreme Western companies, and the city itself, under the leadership of Mr. Holmes and the Metropolitan Street Railway Company, will certainly ex-

tend a hearty welcome to the 1900 convention, and will take good care of it in every way.

* * * * *

The buttons this year were very handsome. The head of the famous Chicago girl was the *motif*, above which were the initials " A. S. R. A.," and below the word "Chicago," while "1899" was in the central disk. The delegates' buttons were in a rich blue, the accountants', in yellow, the ladies', in white, and those given to "others in attendance" were in red. As usual, the buttons acted as "free passes" upon the local surface and elevated railways.

* * * * *

Secretary Penington was, as usual, one of the most popular men of the convention, and his uniform courtesy toward all, and his disposition to do everything in his power to promote the comfort and pleasure of every delegate and supply man, were highly appreciated. His management of the finances of the association has been, as always, excellent, and the surplus is constantly increasing.

* * * * *

Among those usually seen at the conventions, but who did not, for various reasons, attend this year, were John A. Brill, vice-president of the J. G. Brill Company, who is absent in Europe; C. W. Price, proprietor of the "Electrical Review;" Edgar Peckham, president of the Peckham Motor Truck & Wheel Company; John W. McNamara, general manager of the Albany Railway; James H. McGraw, president, Street Railway Journal; Clinton L. Rossiter, president of the Brooklyn Rapid Transit Company; William F. Ham, auditor Brooklyn Rapid Transit Company; Bert L. Kilgour, electrician, Cincinnati Street Railway Company; W. F. Kelly, recently of Columbus, now of Oakland, Cal.; J. B. Cahoon, formerly of Elmira, but now connected with electric lighting enterprise in Syracuse; W. B. Ferguson and E. P. Shaw, owners of many street railway properties in Massachusetts; C. M. Wickar, formerly of the North Shore Traction Company, now of the Chicago Union Traction Company; P. F. Sullivan, general manager of the Massachusetts Electric Companies; Henry C. Payne, of Milwaukee; Richard McCulloch, formerly of St. Louis, now of Geneva, Switzerland; Harry Scullin, of St. Louis, who is not now connected with street railway enterprises; O. T. Crosby, of the Washington Traction Company, now traveling in Africa; John Graham, of Wilkesbarre, and W. J. Johnston, formerly of the "Electrical World," now traveling in the Orient.

* * * * *

The "Street Railway Review" deserved much credit for its enterprise in publishing during the convention a daily edition containing lists of attendants, proceedings of the day before, and descriptions of the exhibits, etc., together with illustrated articles on the Chicago drainage canal, the Union Stock Yards, and other Chicago enterprises. Only those who have been through a work of this kind can understand the immense amount of labor which it involves, the editorial force having to spend practically the entire twenty-four hours preparing matter, correcting proofs, etc. Although many errors will inevitably creep into any work of this kind, so hastily done, they are always excusable and nearly always excused, while the convenience of such a daily resume is considerable. In these daily bulletins and in its special issue of October fifteenth, devoted almost entirely to a description of Chicago as a business, artistic and street railway center, the "Review" has well upheld the traditions of a city noted for its generous hospitality to visitors, and for the care which it takes to make certain that they appreciate its many attractions.

* * * * *

We cordially commend to street railway managers Mr. McCormack's paper on "Train Service and Its Practical Application." It is an able discussion of a problem which is, next to the management of labor, the most important which a company has to solve, i. e., that of running a sufficient number of cars to accommodate the public without eating up all the receipts in operating expenses. It is not too much to say that the net revenue of a road depends upon the management of its car service. More than once has a property been saved from bankruptcy and set firmly upon its feet by a change of management and a better balancing of car service and traffic. It is impossible to generalize upon this subject, as the conditions are so wholly local in every city. All that can be done is to suggest, as Mr. McCormack has done, convenient ways of finding out what service the public really needs and is prepared to pay for. The "car-service engineer" of a street railway is to put these and other methods into practice, and should be a man of the highest intelligence, acumen and energy.

* * * * *

The paper by Mr. Vanderveer on the "Care of Car Equipment" was an interesting one, and upon a branch of street railroading which is of great importance. The old proverb of "a stitch in time saves nine" applies nowhere more forcibly than in the care of railway apparatus, and it is the best kind of economy to keep both the rolling stock and its equipment in good condition by frequent inspection. The speaker limited the advisable night inspection to that only which is absolutely necessary, and preferred to make all repairs by daylight. This opinion was indorsed by all the speakers who discussed this subject, and it will receive general acquiescence. The paper was the prelude to a general discussion on the advisability of running single motor equipments. The experience with single motors, elicited by these expressions of opinion, seems to have been that they require more repairs than double or four-motor equipments, but to us this fact seems attributable not to the number of motors per car, but to a lack of power capacity on the car. Considering the proper equipment of a car from the standpoint of repairs only, the motor repairs per car should vary approximately, though not exactly, with the number of motors on the car, provided, of course, that the single motor equipments have double the capacity of each motor in the double-motor equipment, or four times the capacity of each of the motors in the four-motor equipment. There ought not either to be any great difference in motor efficiency under the same conditions, and any difference which would exist would naturally be in favor of the motor of larger capacity. Both of these points can be readily seen by considering the parallel case of stationary motors. From both a repair and efficiency standpoint, one 80-h.p. motor would give better results, say, than two 40-h.p. motors or four 20-h.p. motors. In railroad operation, however, these two are not the only points to consider. Traction is a very important question, and one to which is intimately connected that of quick ac-

celeration, on which in turn depends the third important question of current economy. On roads where these are desiderata, and among such roads should be classed those desiring quick service and high speed and having grades, the disadvantages of the multiple-motor system will be more than outweighed by its merits.

Treatment of Labor After the New York Strike

We recur briefly to the so-called strike in New York city, in order to bring to light certain incidents of the strike and the after treatment of the employees who so loyally stood behind the administration of the Metropolitan Street Railway Company, when urged to desert it by spurious and self-seeking labor leaders. It is a well-known fact that President Parsons, of the Knights of Labor, was extremely anxious to avoid throwing down the gage of battle, knowing the inevitable result, but was forced into it by a few discharged employees on some of the more recently acquired lines, who desired to make mischief for their own ends. Mr. Parsons was wiser than his associates. On the day the strike was declared many of the men on the different divisions refused to go home after completing their regular hours of service, but voluntarily stayed in the barns all night in order that they might take the place of any of the men who might desert the company. Some of the motormen bitterly resented the presence of policemen on their cars, saying that they had been able to take care of their cars hitherto, and needed no help now. Others fought for the privilege of taking the first car out on the morning of the strike. In general, the utmost contempt for the malcontents, and loyalty to the administration was the rule and not the exception. Such loyalty as this deserved its reward, or so the management felt, though reward was apparently the last thing the men on the system thought of. The question of how recognition could best be given came up for discussion, and some of the employees longest on the system were called in consultation by President Vreeland. Three plans were submitted to them for consideration, one, a large donation to the Employees' Mutual Benefit Association; the second, the granting of a cash present to all men, and the third, the granting of a three days' vacation with pay. After considerable discussion, it was unanimously agreed that the last plan offered something which the men would appreciate more than the others, and for the first time in the history of any great street railway system, so far as we know, the men were enabled to take an outing without feeling that the children must lose a pair of shoes or the wife a bonnet in consequence. The surprise and pleasure of the men at this unexpected act of the company are almost touching, as showing how highly this opportunity to take a little pleasure has been appreciated. One further result of the strike should be mentioned. The men who left the company's service at the beginning of the strike, many of whom did so much against their will by reason of threats or appeals by the strikers, were given twenty-four hours in which to return to service. After the expiration of this time, not a man remaining out was, or ever will be, accepted as an employee by the company. The strongest influences have been brought to bear in some cases to secure the reinstatement of certain men, but in every case such reinstatement has been absolutely and finally refused, it being felt by the management that disloyalty should not be placed on a par with loyalty even in a single instance.

Recent Practice in Track Construction

Among the many changes which the last ten years have made in street railroading none, with the exception of motive power, has been more radical than in the department of track construction for paved streets. Eight years ago the most approved form of street railway track could easily have been defined, but looking back at that period now we can hardly find a single feature of the former construction, with the exception of the form of rail-heads, which is generally accepted as standard practice for paved streets. Changes have been made in the height of rail, weight of rail, length of rail, percentage of carbon, joints and character of sub-construction. To be sure, all of these innovations have not been accepted as desirable by all track engineers, but it is undeniable that many of them, including the increase in weight and length of rail, have been accepted by all, height by most, and joint construction and concrete sub-base by a slightly less number The latest developments in this "modern" construction, as it may be termed, are described quite fully in the papers in this issue by Mr. Butts, of Kansas City, and Mr. Silliman, of Scranton; and while in details the constructions differ in many particulars, both employ the concrete sub-base as a continuous support for the rail. The discussion on Mr. Butts' paper by the American Street Railway Association was, on the whole, favorable for its use for heavy city construction, although there were some dissenters, and it must by no means be assumed that track engineers are universally in its favor. In some respects, Mr. Silliman's construction seems more substantial than that employed in Kansas City. We think the use of steel ties or cross-girders (Mr. Silliman employs for this purpose 52-lb. girder rails every 10 ft.) would be an essential factor in keeping the track in alignment and superior to the exclusive use of tie-rods for this purpose, as the rail is better maintained in an exactly vertical position. With the imbedding of the steel ties in the concrete, however, difficulty will be encountered in making the track connections when the rail is renewed, unless the old tie is torn up. The joint connections, of course, are also different, in one case being riveted, and in the other cast-welded. There is also a variation in the form of concrete sub-base used; in Scranton the concrete is laid entirely across the track, while in Kansas City it is laid in trenches under the rails. We presume the latter construction would have been employed in the former city if the pavement had already been laid on concrete, and will be employed when it comes to renew the rails. Neither of the speakers referred to the subject of track renewals, which is, of course, an important question where a concrete sub-base is employed, as where the rail is imbedded in concrete the entire old base must be renewed when the rails wear out and new rails are substituted.

While the use of concrete sub-base is increasing, the use of wooden ties for city work has also many advocates. The latest and best track construction in Chicago is on wooden ties, mounted on a broken stone ballast, and it is interesting to note that in the most recent work in New York City, that of the Third Avenue Railway Company, the use of

wood in sub-construction was considered so desirable that it is being employed in the form of stringers under the rails, even in electric conduit construction. Undoubtedly, the use of wood in track construction conduces to easy riding, a very important feature, as shown by the fact that in the work of the Third Avenue Railway Company, already cited, steel springs are being used under the rails in the old construction, where the shape of the existing yokes did not permit the introduction of wooden stringers under the rails. Independent of the question of durability, the result sought for in this construction has certainly been accomplished, and the elasticity given the track is very noticeable.

We are unwilling to state that either the concrete sub-construction or the wooden tie construction is the most desirable under all conditions of track construction in paved streets. As a matter of fact, we believe that the special circumstances which warrant the introduction of each will be determined by experience. At present the concrete sub-base seems to have the advantage of durability. As it would have to be renewed when the rail wears out, however, there is no advantage in making it longer lived than the rail, which is the really limiting factor. On the other hand, if the life of the rail varies inversely with the number of tons passing over it, while in that of the sub-construction, time is the principal factor, the durability of the sub-construction is a more important question on roads of comparatively light traffic than on those of heavy traffic. It is not impossible, therefore, that we shall find practice in paved streets following the somewhat anomalous line of using the more substantial concrete construction on the smaller roads, and the lighter and more elastic wood construction on the roads of heavy traffic.

A Question of Units

Mr. Mackay, in his paper on "Car Mileage," makes a strong plea for the use of the "motor-car hour" as a unit in place of the "car-mile run," now in quite general service. The motor-car hour, as he defines it, is the car mileage divided by the average speed in miles per hour. If, for example, a railway runs its cars at an average schedule speed of 8 miles per hour, and they aggregate 2000 miles per day, there would be 250 car hours run, and the cost per car hour would in that case be eight times the cost per car mile. The advantage of this unit is found chiefly in comparing roads, or divisions on a large system, where schedule speeds vary greatly. There is no question that the principal part of the great variation in cost per car mile shown by different roads is due to the differences of schedule speeds. In a road running at 20 miles per hour, for example, and paying its conductors and motormen 20 cents per hour each, the transportation wages amount to only 2 cents per car mile, whereas in a city road running at, say 6 2/3 miles per hour, the equivalent cost is 6 cents per car mile, with the same rates of wages paid. On the motor-car hour basis the transportation wages would be the same, viz.: 40 cents per car hour; the two roads will, to that extent, at least, be placed on an equal basis, and the effect of mismanagement or poor economy in departmental work will be more clearly brought out. This is Mr. Mackay's argument, and it is undoubtedly a strong one from some points of view.

The attempt to find a single unit of measurement which shall gage the respective efficiencies of management of two street railway properties is, however, as futile as was the search for the philosopher's stone in the middle ages. The difficulties are inherent and insurmountable. Street railway operation is made up of so many processes wholly different in their nature that they cannot possibly be brought down to expression in any one form, even on a single property—much less in comparing two properties having widely different conditions. How true this is may be seen by inspecting some of the detailed operating expenses which go to make up a total. In the department of transportation we can, to be sure, pro rate nearly everything in car service upon a car-mileage or motor-car hour unit. If we pro rate operation of power plant also upon this unit, it will give us some results of value, from a transportation standpoint, although we cannot by this means gage the relative economy of different power stations, but must for that purpose use the kilowatt-hour unit. In the maintenance accounts, however, we run across trouble at once. Maintenance of cars and their electric equipment can be gaged by the motor-car hour or car-mile unit, but directors would get a much clearer understanding of the relative economies in different comparative reports of operation if the accountant should pro rate maintenance of track and roadway upon miles of track; maintenance of electric line upon miles of road; maintenance of steam and electric power station plant on kilowatt output, as a part of total cost of power; or should express all these costs, together with maintenance of buildings and fixtures, in the form of percentages on original cost. So, too, in the department of general expenses, what a board of directors would look for from their accountant is a statement as to what percentage of their gross receipts is being used for general expenses of administration in detail and in toto, and whether this percentage is increasing or decreasing. We do not mean to say that all these items in operating expenses are not to be expressed in the car mile or motor car-hour unit, for the manager and the directors often wish to get an idea of the relative proportions of each item of expense to the total, and this can well be shown in either of these units, but it is certain that, in comparing many of these items outside the transportation department, from year to year, in order to see where economies are possible, they will find the motor-car hour or car-mile unit absolutely useless. If these things are true of an individual road, how much more must they be true when comparing, as Mr. Vreeland said, a mountain road with a plain.

The truth is that we must have a large stock of units in order that the directors and managers of a property may be able to effect the economies which it is the object of all accounting to facilitate. The motor-car hour is a valuable addition to this stock, and Mr. Mackay is to be given due credit for bringing it so prominently before the accounting world and explaining its merits. While it is not, and never can be made to be, the touchstone which will measure efficiency of management of two different properties, it will help the manager of a large corporation to learn more about the work of his respective division superintendents, because they cannot plead differences of speed as being responsible for differences in result. We believe, however, that the car-mile unit is firmly entrenched in the practice of so many companies and is, on the whole, so satisfactory in making comparisons from year to year on the same systems, that it is not likely to be displaced.

In the final analysis the presentation of operating results by the accountant in any or all units is not the *end*, but only the *beginning*. It is the manager's duty to explain these results to his directors and stockholders, to show why the cost per car mile of car service, for example, was greater this year than last, or to state with due satisfaction that by such and such means he was able to bring the cost of power down this year to 1½ cents per car mile, while it cost 2 cents last year. It is the business of the accountants to make this work of explanation as easy for the manager as possible, and for this purpose a table of detailed comparisons in appropriate units separate from the main presentation of results should accompany every profit and loss account.

How Can Street Railway Investments be Made Secure and Remunerative

The paper on this subject just delivered before the American Street Railway Association by Charles T. Yerkes, one of the most successful investors in street railway properties in America, is certainly worthy of careful attention, and is full of suggestions and ideas, upon which, however, public opinion is by no means unanimous. Mr. Yerkes first describes the tremendous physical and financial differences between the horse railways of twenty years ago and the cable and electric railways of to-day, referring especially to the great investments now required as compared with those necessary for horse railroading, and he considers that the investment risks now are such that if twenty-year franchises were fair under the old regime, two hundred-year franchises would be equally fair at present. A long charter or franchise tends more, he thinks, to the greater security of street railway investments than any other one element. Mr. Yerkes believes that street railway companies should pay for their privileges by turning over to the public treasury a fair percentage of the earnings of the company, but that it should be borne in mind that a company serving a large city must always carry a large amount of unproductive mileage, which the future only is to make valuable, and therefore cities should not make extortionate demands upon the companies. He advocates the appointment of State commissions to carefully and intelligently supervise the operation of street railways in much the same way as is now being done in several of our States. Finally, to the end of making street railway securities more secure, Mr. Yerkes advocates straightforward dealing with the public, and a broad and liberal policy in introducing improvements.

All these suggestions are good and valuable, but they do not reach the heart of the problem. The more we examine into the reasons for the increasing number of controversies between municipalities and private capital engaged in public service industries, the more certainly is the conviction forced upon us that *the only way in which most of the grave problems which confront street railways to-day can be solved, and street railway investments can be made both secure and remunerative, is by making friends with the public and taking it into a bona fide partnership of profits.* At the root of all our troubles of to-day—excessive taxation, labor strikes, "cruel and unusual" punishments of various kinds inflicted or attempted by politicians—lies a grossly exaggerated idea of street railway profits, and this idea is fostered by *secrecy*. All of us in the business know that street railway profits are not excessive, but are, on the contrary, small, while the business itself may be classed as "extra hazardous." The comparatively few men who have apparently, or actually, grown rich from their street railway security holdings, have done so, as a rule, through the capitalization of expected profits, not the actual receipt of real ones. In nine cases out of ten where the annual profit and loss accounts have seemed to show a large return on investment, it is because depreciation of plant and equipment has not been properly taken care of, as is universally done abroad, or else because an open "construction account" has been charged with what are really operating expenses, in order to serve the purpose of those who are trying to unload their stocks upon the public.

It is hard—probably impossible—to bring these facts home to the public, particularly because the truth is kept from them by both politicians and street railway managers themselves, though for differing reasons. The manager is the agent of his company's security holders, and cannot take any radical action which would depreciate the value of their securities among investors. The politician, even if he knows the truth, which he rarely does, perhaps, would not ordinarily hesitate to climb to power on a purely demagogic appeal to public ignorance and prejudice. Meanwhile, secrecy is maintained, and the burdens of taxation are piled on heavier, until, from one cause and another, the final crash comes and the property is bankrupt.

A partial remedy for this state of things is the non-partisan State commission, which Mr. Yerkes advocates. Such a commission is found in Massachusetts and New York, and in Massachusetts, particularly, its functions have been so fixed by law and interpreted by the courts, as to really protect the public against overcapitalization and "wild-cat securities." It is impossible to-day to overcapitalize street railways in Massachusetts. The Railroad Commissioners will permit issues of stock and bonds together only to an extent warranted by the actual cost of duplication of all the tangible assets, and the bond issue must not exceed one-half the stock issue. Organization expenses even cannot be capitalized, and if there be at any time an impairment of capital account, as shown by inventories dividends must be reduced or suspended until the impairment is made up. The commission even fixes the price at which stock shall be offered to the public, never putting it below par, and frequently providing that a heavy premium shall be paid into the company's treasury—not into private hands. Such protection as this is genuine, permanent and desirable from every point of view except that of the man who wishes to make money too rapidly, and street railway investments are highly regarded in Massachusetts as being secure and reasonably, though not largely, remunerative.

In spite of these carefully made provisions, however, there is a growing agitation even in Massachusetts for public ownership of street railways, and unless a better and more logical plan than this semi-socialistic one is found, there is grave danger that the immense advantage to the public of private ownership or trusteeship of this industry may eventually be lost. We need not here repeat the arguments against municipal ownership of street railways, except to epitomize them by saying that never in the his-

tory of the world will a municipality, with its 50,000, 100,000 or 1,000,000 inhabitants as "stockholders," represented by fifty or one hundred councilmen, as "directors," handle any public service enterprise with the same promptness, decision, breadth of view and outlook for the future, as will be done by properly encouraged private capital, managed by a half dozen responsible trustees. In a thousand ways, more or less indirect and unrealized, the people will be the poorer for a municipal ownership experiment, even should their treasury be slightly the gainer.

What then is the true remedy if it is not found in the Massachusetts plan? In what way can municipal ownership agitation be stopped and the immense benefits of private ownership be retained for the public good? Is there any one plan which can be put in universal application with justice to all concerned?

Possibly not, but if such a plan be found it will surely involve the profit-sharing principle in some form, together with absolute publicity in every department of the business. In a plan of this kind the expenditure of gross receipts might be made on some such basis as the following, the charges on receipts taking precedence in the order given:

1. *Operating expenses,* including a proper allowance for depreciation.

2. *State and local taxes* paid on real estate and personal property—the ordinary burden of citizenship.

3. *A reserve fund* for accidents, uninsured losses of various kinds, and other contingencies.

4. *An amortization fund,* to insure a return of invested capital at end of franchise life.

5. *An employees' benefit fund* to provide against sickness, accidents and old age.

6. *A minimum* (e. g. 4 per cent) *annual return* on the private capital invested.

7. Equal division between the municipality and the private capital invested of the remaining profits.

With such a plan as this, embodied in contract form, between municipality and company; with regular monthly, quarterly and annual reports of operations, duly audited by city officials; with arbitration of disputed points by a State railroad commission; and, above all, with absolute good faith on the part of both city and company, is it possible to doubt that demagogues and political "strikers" would be driven out of business so far as street railway matters are concerned, while, the interests of the municipalities and the companies being substantially identical, the present distressing conflicts would almost entirely disappear, and street railway investments would become both secure and remunerative?

Finally, the policy of distributing street railway securities locally—a matter not referred to by Mr. Yerkes in his paper, but touched upon by Mr. Vreeland in his discussion—is one which should be adopted by every company, even at some sacrifice of time, convenience and money. In disposing of bonds to banking houses, as large a proportion as possible should be reserved for sale to local capitalists, either by the companies direct or by the bankers as financial agents, and as much stock as can be spared should also be placed at home. In cases of this kind it is dangerous to be *isolated* in a community, for a company is thereby subject to the attacks of "strikers" or demagogues, without friends to help it fight its battles. Fifteen or twenty prominent local men as stockholders can bring immense influence to bear at times in preventing trouble, and if the number can be made 100 or 1000 or more, thereby making an even larger portion of the public sharers in the enterprise, so much the safer is the invested capital.

Franchise Valuations

A franchise may be defined as a special privilege granted by public authority to an individual or a body of individuals. The value of a franchise may be large, small, nothing or worse than nothing—the latter if it involves losses or obligations which cannot be escaped. The true value of a franchise, when it has a value, is an amount equal to *the capitalization of excessive—not of total*—profits. Every investor has a right to expect a reasonable rate of return upon his investment in tangible assets, organization expenses, etc., this rate varying with the current rates for money in the particular locality where the investment is made and upon the general estimate placed on the safety of his enterprise in comparison with that of others, into which he could put his money. If, because of the possession of a franchise conveying special privileges, he gets a rate of return larger than the average, the capitalization of the excess, at the ruling interest rate, is the value of the franchise.

Suppose, for example, that a company obtains a thirty-year street railway franchise, that it pays $1,000,000 for plant and equipment, and earns $50,000 per annum for thirty years, in a community where the ruling rate for an equally safe investment is 5 per cent. The value of its franchise is nothing, since the same return can be obtained from an investment involving no franchise. If it makes $100,000 a year for thirty years, the value of its franchise is $1,000,000, since, because of the franchise, 5 per cent can be earned upon $2,000,000.

This is a fair and reasonable method of arriving at a franchise valuation, and where the true investment account can be ascertained, distinct from overcapitalization, the value of a franchise can readily be obtained at the end of its life. If, however, the attempt to do this is made earlier, estimates, based on more or less fallible judgment, must necessarily be employed. It may be expected, for example, that general market interest rates will fall during a long time franchise, thus increasing the franchise value by increasing the capitalization factor. The value of real estate may also go up, thereby increasing the selling value of that portion of the investment and increasing the total net profits for the period. On the other hand, equipment may deteriorate and earnings, gross and net, may be greatly reduced through accidents, competition or "improvements in the art" necessary to obtain at whatever cost.

At a time when municipalities seem to be combining to drive street railway companies out of business by excessive taxation, it is necessary to occasionally clear the atmosphere by defining first principles, and we trust that the time will come when there will be less loose and indefinite talk about franchise valuations than is now so generally heard.

A Word of Appreciation—and Explanation

It is with much pleasure—tempered, however, with some surprise—that we have received the congratulations of a thousand or more (so it seems to us) friends and well-

wishers at the convention and elsewhere, on what they are pleased to term "that magnificent 'World's Practice Number' of yours." Pleasure in such congratulations is always natural, for it indicates appreciation of good intentions, if not of good work. The surprise comes in finding that the achievement in this particular case should be considered so remarkable. It is true that our "World's Practice Number" was a large issue, containing no less than 163 pages of reading matter and 276 pages of advertising, but this result compares with our regular fall convention numbers of previous years only in about the same way that the general prosperity of 1899 compares with that of 1898. Possibly an issue of this kind, dealing as it does with electric railway practice all over the world, and bearing within it so many evidences of the close engineering and commercial inter-dependence of the different countries, in these days of enterprise, competition and intelligent study of results, is needed to demonstrate the broad international character and world-wide connections of a periodical which is universally recognized, we believe, as the leading exponent of the street railway industry. The very fact that British, French and German manufacturers used between forty and fifty pages of our October issue to advertise their material and supplies among tramway purchasers, not here, but in Europe, Asia, Australasia and South America, and that no other foreign or American paper is used to anything like the same extent, is certainly significant, but it did not occur to us, until hearing the many expressions of surprise at this large foreign patronage, that the position of the STREET RAILWAY JOURNAL abroad may not be fully understood in America. We may be pardoned then, perhaps, if we state here, for the benefit of those who have not closely followed our work in foreign fields, that for some years past we have been publishing two regular monthly editions of the STREET RAILWAY JOURNAL, one, the American edition, intended for circulation in the United States and Canada, and the other, the International Edition, for circulation in all other parts of the world. Each edition contains considerable matter not found in the other, though it is intended that nothing shall be omitted from either edition of interest to its special clientele. In each issue of the International Edition appears a digest of contents in German, Spanish and French, and for the benefit of the combined service we have a staff of regular editorial representatives and occasional correspondents in the principal capitals of the world, composed of leading engineers and managers, of the several countries.

Partly as a result of this more recent work, but largely through the inheritances of earlier years, our foreign subscription lists contain not only the names of practically all the principal European engineers, tramway managers and manufacturers interested in improved tramway and railway motive powers, but cover such distant countries as Persia, New Zealand, Java, Turkey, Trinidad, Siam, Japan, Hawaii and all parts of Africa and South America. The little unpleasantness now going on in South Africa, for example, directly affects us, inasmuch as we cannot be sure that our current issues will reach our numerous subscribers in and near the seat of war, in Kruegersdorf and Pietermaritzburg, Natal, Johannesburg and Pretoria, South African Republic.

The STREET RAILWAY JOURNAL is not a *local* paper.

"A better convention has never come to Chicago in the course of my experience." So spoke the genial chief clerk of the Auditorium on Friday night, and he followed it up in explanation by saying that it was a convention which "took care of itself," did not overstep bounds, made no complaints, understanding the difficulties of the situation.

Proposed Resolution for Bringing About a Standard Determination of Cost of Public Service

The following resolutions, prepared by Allen Ripley Foote, have been presented for action to a number of economic, municipal and private industrial associations, with a view to bringing about a scientific determination of the cost of public service, and of thereby furthering the comparisons between the cost of public and private ownership to the advantage of all concerned. Among others, the executive committee of the American Street Railway Association has these resolutions under consideration:

Whereas, The American Street Railroad Association has discussed certain features of municipal public policy relating to the ownership and operation of public service industries, and whereas, such industries must necessarily be owned and operated by public or private capital, and, in either case, the application of a definite system of regulation identical in all of its details for both public and private ownership is fundamentally essential to promote and protect the welfare of users, taxpayers, employees and investors,

Be it Resolved:

First—That practical civil service regulations, strictly and continuously enforced in the case of public ownership, and a just system of profit-sharing in the case of private ownership, are necessary provisions to safeguard the interests of employees, and to insure efficient economic management for the service of users and taxpayers.

Second—That a system of accounting, uniform throughout the State, prescribed and audited by authority of a general State law, designed to show the true and entire cost of every public service industry, identical in every particular for public and private ownership and operation, is an indispensible condition to secure intelligent and just regulation.

Third—That a general State law should specify that there should be included in all statements of costs, used as a basis for determining prices to users and taxpayers, interests on the investment at the rate paid on its bonded debt by the municipality in which the industry is located, a sufficient provision for insurance against loss by accidents of every kind; the amount of taxes relinquished if a publicly owned industry, and paid, if a privately owned industry; an ample provision for insurance against the impairment of investment; the true and entire costs of all materials used and salaries and wages paid, and an accurate statement of all miscellaneous expenses.

Fourth—That prices to users and taxpayers should be based on cost, plus a provision for the payment of all capital secured by taxpayer or the sale of bonds in case of all publicly owned, and cost plus a legally limited profit in case of all privately owned industries.

Fifth—That prices should be determined for periods of five years.

Sixth—That all service rendered to private and public users should be valued and paid for at prices determined, as specified in number four. All free service should be prohibited.

Seventh—That no service should be sold for less than its cost, and no discrimination in price shall be allowed between users taking service under like conditions.

Eighth—That the divisible profits of private ownership and operation should be determined and limited by a rate upon the investment, which shall be equal to twice the rate per cent paid on its bonded debt by the municipality in which the industry is located, in all cases where costs are calculated and allowed, as specified in number three.

Ninth—That all profits in excess of the legal profit should be divided equally between the municipality and the private owners.

Tenth—That in making contracts with private corporations for the purpose of carrying the foregoing regulations into effect, the initial investment used as the basis of calculations should be determined by process under the law of eminent domain, or by arbitration, as may be mutally agreed upon between the municipality and the corporation.

Eleventh—That this contract should provide that at the expiration of every period of five years the municipality shall have the option of paying to the corporation the full amount of its investment and thereupon taking possession of the property, and thereafter operating it as a municipal industry, and in case this is not done, that the prices shall be determined for another period of five years, and the contract continued in force without further change.

Twelfth—That this system of public regulation is preferable to public ownership and operation.

NOTES AND COMMENTS ON THE ACCOUNTANTS' CONVENTION

BY A. O. KITTREDGE, C. P. A.

"Well, what did you do there, anyhow?" or some similar question, is likely to be the greeting of all of those who were in attendance upon the convention of the Street Railway Accountants' Association of America, as often as they are met by those who are interested in the general proposition of perfected accounts, and who were unable to be present. The subjects announced by the programme for discussion were such as are of interest to all street railway men. They are of special importance to those companies who have taken membership in the organization. But, at best, the attendance at the several sessions was only about one-third the membership. It would seem, therefore, that the question would have to be very widely answered if the general desire for information is to be satisfied. Right here becomes apparent the usefulness of the silent member, who takes notes while others talk, and the utility of the press, that makes known to all the results of his observations. What, then, was done by the accountants' convention? A verbatim report would fail to reflect the lights and shadows of the occasion, even though it recorded all the stated motions and faithfully reproduced the speeches. It is an effort to supply what the verbatim report cannot convey that these notes and comments are penned. First, let it be stated that what was done included a part of what was suggested by the programme, and much more that was spontaneous to the occasion. As I look back to the days devoted to the meetings I am inclined to the opinion that the less importance attaches to those matters which were in the original programme, including those that were covered by formal motion made and seconded, and the far greater importance to those matters which were unexpected, and which by the manner of their presentation amounted to little else than apropos suggestions and genuine thought provokers.

* * *

There was more of the practical in the welcoming address of L. E. McGann, Commissioner of Public Works, who, as the representative of the city of Chicago, welcomed the accountants, than is usually found in such efforts. He invited the accountants, as well as members of the American Street Railway Association, to visit the City Hall to examine into the methods of doing business there in vogue, and particularly to inquire into the methods of granting railway franchises. He very appropriately remarked in connection with this invitation that the question of granting franchises is as great as that of accounts. He declared that much of the popular prejudice that exists with respect to such matters could be designated in a very few moments if only the methods were inspected. Only two or three of the accountants were able to find the time to accept this invitation, but those that called at the office of the commissioner reported both a profitable and highly enjoyable hour. President Calderwood's acknowledgment of Mr. McGann's welcome and invitation was in his happiest vein. In characterizing Minneapolis as a suburb of Chicago he touched the heart of every Chicagoan present.

* * *

Several prominent thoughts were left in the minds of his hearers by the annual address of President Calderwood, among which were the following: The street railway business, notwithstanding the energy and capital invested in it to date, has not yet been developed, in the estimation of men competent to express an opinion, to exceed one-fifth part of its possibilities. Accounting is the vital element of all branches of business, street railways not excepted, and the economies of accounting, both as to the character of the results obtained and stated, and the cost of performing the work, are of the utmost importance every where. Keeping in mind the fundamental principle of comparison, President Calderwood, often complimenting the association on what has been accomplished in the classification of expense accounts, pointed out that before the association will have fulfilled its mission it must have a unit of comparison. Just what that unit should be he did not in the least intimate, leaving its determination to the association, to be developed, perhaps, by the discussion of Mr. Mackay's paper on "Car Mileage." The address also referred briefly to the action of the Association of Railroad Commissioners in indorsing the classification worked out by the street railway accountants, and also to the work of the secretary in the matter of blanks and forms. President Calderwood closed with a feeling appeal to the members of the association to avoid hobbies in accounting, and to be careful to give the managing officers of the several roads only such salient facts as are likely to be useful to them.

* * *

The report of the executive committee presented by Mr. Wilson was a model of brevity. A description of it would require more words than the report contained. The committee held three meetings during the year, and had five mail votes, admitting thirty-four new members (companies). A change in annual dues from $10 to $20 was recommended. The question of a change in time and place of meeting, so that the accountants would not assemble when and where the American Street Railway Association was holding its sessions, was recommended for consideration. The books of the treasurer were reported to be correct. The secretary and treasurer's report, on the other hand, went into details, and occupied much more time in reading. A detail list of the thirty-four companies admitted to membership was given. The fact that both the great companies of New York City were included, and that London, England, and Glasgow, Scotland, were also represented was received with special gratification. The association has had a total of 103 members since its organization. Three have dropped out, leaving the membership at the time the report was written at an even hundred. There were several additions during the days of the convention. The financial report showed a deficit of some $75, which means that, with the rigid economy which has characterized the management from the start, many expenses belonging legitimately to the association having been paid out of private funds, the income does not suffice for the work of the body. This deficit was more than made up by voluntary subscriptions before the convention adjourned, and the proposition to double the dues (commencing Jan. 1, 1900,) was carried. One motive that influenced this latter measure, and which was prominently brought out in the discussion, was the tendency to consolidation among street railway companies, resulting in a lessening of the number of possible members. With an assured income of $2,000 for the ensuing year, as against $1,000 for the year just closed, it would seem that the work might go on without serious financial embarrassment.

The paper by Mr. Mackay, to which all had looked forward with interested anticipation, was in a sense an attack upon the "car-mile" as a unit of comparison, and a defense of the "motor-car-hour," with incidental reference to the shortcomings of such units as the "passenger-mile" and others more or less in use. Not a little interest centered in Mr. Mackay's account of the questions he had addressed to a considerable number of street railways throughout the United States and Canada, and the answers thereto. From these it appeared that out of ninety-four roads answering as to the basis upon which mileage is computed, seventy-three depend upon conductors' or motormen's reports, fifteen on foremen's, dispatchers' or switchmen's reports, and four upon time tables. Of ninety-seven roads answering the question of keeping a record of the mileage of each car, fifty-one reported that such records are kept, while forty-six replied in the negative. Of ninety-three roads answering as to means of verifying mileage figures, forty-five reported none but care in computing, twenty-eight depended upon time tables, eight on dispatchers' reports, four each on foremen's reports and pay rolls, three on motormen's reports, and one upon trip receipt returns. It further appeared that of ninety-seven roads answering the question of including "dead mileage" in their computations, fifty said that it was not included, thirty-six said they did include it, and eleven declared they have no dead mileage. In the matter of trailer mileage forty-six companies reported no trailers used, thirty-seven who use trailers more or less of the time, include trailer mileage in their figures, while eleven declared that trailer mileage was omitted, and one road reported that trailer mileage was taken at one-half. On trips lost, fifty-seven roads reported allowances, and thirty-seven said no allowances were made in this regard. The question as to what constitutes a car-day produced some peculiar figures. Forty-eight companies reported that "cars operated per day" is not used by them as a basis for comparison of earnings. Forty-four companies do use this unit, but give it different values. Thirty-one of these companies call the car-day eighteen hours, four put it at fifteen hours, and three have it at seventeen hours, while four others, being a single instance, each gave the figures sixteen, seventeen and one-half, nineteen and twenty hours. Two companies reported on the basis of miles in place of hours, giving the figures eighty and 115 miles respectively. These statistics are interesting, if for no other reason, because they show wide diversity in point of view, as well as the differences that exist in current practice.

* * *

Mr. Mackay's conclusion from his investigation and study of the subject was that such mileage carefully computed, all dead miles included, and with the trailer eliminated, there would be available a unit uniformly applicable to all electric systems and available as soon as the question of speed is adjusted. In his remarks he had dwelt upon the question of speed as between city service and interurban cars, showing that increase of speed does not materially increase the cost of operation, and demonstrating that in the case of interurban cars running from two to four times the speed of city lines, the cost per car-mile would be less, while the showing on the basis of passengers carried would be more, by reason of the longer haul. The new unit, Mr. Mackay called the "motor-car hour," meaning car-miles divided by the average rate of speed. This unit he advocated using for both earnings and expenses, and in closing his address pointed out how various suggested difficulties could be met and overcome. That the convention did not agree with the speaker in his conclusions in all respects became apparent as soon as discussion was commenced. It also became very evident that there were almost as many views as there were speakers, thus demonstrating over again just what Mr. Mackay's carefully gathered statistics had proven.

* * *

Mr. Vreeland, of the Metropolitan Street Railway Company, New York, who opened the discussion of Mr. Mackay's paper, took a somewhat peculiar, but extremely interesting, course to show why and wherein he could not indorse the unit named for use upon the lines within his control. His opening remarks were slightly biographical. He briefly traced his own railway history, by way of explaining how and why he was tinctured with some of the views which prevail among the managers of the steam roads of the country, in the matter of records and units of comparison. He described the peculiar conditions under which street railways in New York are operated. He pointed out that as many as 5000 horses are yet at work in the street car systems of the metropolis, and that both cable and electric lines are in use. Congested traffic is the rule on all the down-town lines at certain hours of the day. When a car starts out it is uncertain whether it will make the entire trip or part of the trip, because of being turned back by an inspector at some point en route. Speeds differ not only as between different lines, but as between different sections of the same line, and as between different hours in the day on a given section of any of several lines. In view of all these perplexing conditions the speaker declared that he had found the "car-mile" the only satisfactory unit of comparison, or basis of statement of results. He mentioned that the unit in use in New York is also in use in Philadelphia and some other of the large Eastern cities. No trailers are used in New York. Mr. Vreeland said that at present cars of various lengths are in service, ranging from 18-ft. horse cars up to the long double-truck electric cars on some of the more recently equipped lines. He said, in answer to a question, that no attempt was made to take the element of speed into consideration in the statistical statements of his company, and pointed out that it would be impossible to do so for reasons already mentioned.

* * *

The one remark dropped by Mr. Vreeland that attracted most attention, and that was referred to most frequently in the discussion in the convention, and also in the talk of the accountants as they rode together on the excursions, was that in which the operating expenses of a steam road in a mountainous section were compared with those of a road in a prairie country. The first, he said, might show operating expenses of 80 per cent, while the other was as low as 50 per cent. This demonstrated not that the first was poorly and inadequately managed, but that the cost of hauling freight and passengers up heavy grades was more than that of hauling them over a level road. Computations by percentages, he pointed out, were never satisfactory, because in percentage statements it is impossible to indicate the conditions under which the traffic is conducted and the physical condition of the road and its equipment. The comparison of mountain and plain was very quickly grasped, and the illustration was frequently employed in enforcing what many members contended is a fact, that no single unit is possible, taking all the street railways of the country into account. Differences in roadway and equipment are indisputable. Weather conditions, as between the extremes of North and South, are facts to be considered, and numerous other matters that will occur to the mind of every practical railway man are to be reckoned with.

* * *

Mr. Wyman, of the New Orleans Traction Company, thought possibly the motor-car hour might overcome some

of the difficulties encountered with the car-mile unit. Mr. Duffy declared that the motor-car hour would help out a comparison between the road in the Rocky Mountains and one on the prairies of Illinois. Col. Heft, of the New York, New Haven & Hartford Road, declared that the question is one that is governed entirely by the conditions which exist upon the road that is being operated. He said the motor-car hour on the New York, New Haven & Hartford Road would be very misleading, because during certain portions of the day two trailers are used, while during other portions, three, four, or even five, are employed, while in still other cases the motor-car alone is enough for the traffic. The car-mile unit has been adopted by his company. He remarked further that all such questions as the unit of comparison or basis of statement of results must be settled in the light of the conditions that exist on each of the several lines, and that no fixed or stereotyped rule is possible. He would cordially welcome a rule universally applicable, to be used alike by all companies, but from present light such a consummation seems well nigh impossible.

* * *

Mr. Wilson, referring to the Boston roads, said that over 300 routes per day were run, all of them being different lengths, and such cars running at different speeds. The conditions are such that no other unit than the car-mile would answer. He did not think it fair to compare city routes with interurban routes. Each class ought to have comparisons of its own. The same unit was not equally applicable to both. Mr. Ross remarked that the question of the car-mile and the motor-hour is entirely a local one. He believed the ratio of expense to earnings to be the only proper basis of comparison. He did not think it feasible to compare a large road with a small one, nor yet a road where there is no snow to one that is obliged to spend a large sum in removing snow every winter. When Mr. Mackay introduced his second diagram, in which were compared results of different months having different incomes or earnings, but with practically unvarying operating expenses, the discussion waxed warmer. The diagram showed earnings of $100,000, $120,000 and $150,000 for January, May and July, respectively, and $60,000 operating expenses for each. The percentage of the latter to earnings was shown to be 60, 50 and 40 for the three months respectively. The earnings per car-hour figured $1.67, $2 and $2.50 respectively, the motor-hours throughout being 60,000. In explaining this diagram, Mr. Mackay pointed out the evident unfairness of comparing different roads upon the basis of percentage of expenses to earnings. To say that the month of May showed operations 10 per cent cheaper than January, as above, when the operation expenses were the same for both months, the amount of traffic or earnings representing the sole difference, would be absurd. Mr. Ross then asked why not make it on a per mile basis, instead of a per hour basis. Continuing, he enforced the point already made that there are different conditions distinguishing every road that is examined. He declared he could not see how the car-hour basis would bring the correct result. Mr. Mackay then alluded to efficiency of service, saying that in winter, when less cars are required, less are run. Mr. Hibbs, with, perhaps, a suggestion of impatience in his tone, here inquired if, as a matter of fact, there is any satisfactory basis of comparing roads that operate under different conditions?

* * *

J. K. Newman, president of the New Orleans & Carrollton Street Railway Company, after explaining that a president must necessarily interest himself in the accounts of the property in his charge, said: "You may establish any basis you please, whether it be car-hour or car-mile, but you cannot compare different roads operating under unlike conditions with each other." He declared himself in favor of the car-mile basis, and then explained how in his own office the car-mile, the car-hour and the percentage method were all used, each showing some fact not revealed by the others, and, taken collectively, giving the whole situation in a form to be available to the management. Mr. Mackay here interrupted to the extent of declaring that in the light of the speakers who had so far discussed the question it was apparent that nothing had been accomplished. Mr. Wilson, by way of pacification, said that he did not think that the work of the association would be thrown away, even though no basis was arrived at. Mr. Dimmock then inquired as to the comparison of mileage to be made between a long haul and a short haul, and whether with a long double-truck car the mileage would be counted the same as with a single-truck car, if both went only 1 mile? Mr. Mackay answered in effect that the small car would cost less than the large car, but that there would be less efficiency, and accordingly that the showing would be more particularly in the earnings. The expenses would not show in the large car as they should. Mr. Dimmock next inquired if both cars, long and short, run one hour or any other period of time, would be regarded as running the same. He said he knew of some roads where the short car was counted double the long car. Mr. Mackay replied that the comparison should be on the actual time the car was out, without regard to the length of the car.

* * *

It was left to Mr. Ford, of New Orleans, to close the debate, and this he did by pertinent references to what is the rule with his company in these matters. He believed it impossible to find a rule that can be considered as applying to all street railways in the country as a basis of comparison. While using the car-mile, it is his rule also to submit an analysis of the monthly results upon a percentage basis. His statement also shows the earnings per car-day of eighteen hours, and likewise the expenses per car-day of eighteen hours. Both earnings and expenses are shown per car-mile. Continuing, after mentioning that trailers are used on one line, he said: "I can see that on almost any basis it would be hard for us to compare with another road that is not operating under the same conditions." His advice to the association was to show the managers what the figures really mean. Let them have the comparison of one month with another on the basis of motor-car hours, of car-miles, of car-days, the earning percentages, the expense percentages, and whatever else is possible and appropriate.

* * *

In an account of this nature, written largely from memory after the final adjournment, it is sometimes difficult to discriminate between what was said in the meetings and what transpired relating to the same subjects as they were talked over in the hotel lobbies. Perhaps it is not necessary to try to do so. All that Mr. Ford had said was cordially indorsed by Mr. Duffy immediately after adjournment and before all the members had got their overcoats and hats on ready for departure. He said he had been in the habit of displaying results for the benefit of his managers in just as many different ways as possible, in the knowledge that what was not clearly indicated in one way would be brought out by another. Mr. Harder, of Kansas City, offered remarks of like import, as did also Mr. Simpson, of Augusta, Ga.

* * *

In the hotel a president and two accountants continued

the discussion of a unit of comparison to be universally applicable. The street railway president, who is also an accountant, did most of the talking. "Why," said he, "the proposition of a single unit is preposterous. There must be taken into account a lot of things, among which are the weight of the car, the length of the car, the horse power of the motor, the efficiency of the motor, the grade of road, the character and physical condition of the track, and ever so many more. A comparison, to be of any real value, ought also to include in some way a reference to earning capacity. I can readily see how a conference might result in fixing a unit for the car, and one for the track, another for the power, and one for receipts, and still another for time and wages of the operation, and no doubt as many more as are necessary, but to get an expression that shall include all these in one, and be fair in all cases, seems to me not only impossible, but an absurdity on its face. The variations in the underlying conditions, impossible of expression, would render comparisons on such a basis of no value whatever. It is barely possible, if the railway accountant had all the receipts of the road and the contents of the National Treasury, in addition, to defray the expenses of his department, and a span of life ten or twenty times the usual average, a plan might be worked out for grading or judging street cars and their operation, after the general method that obtains with horsemen, bird fanciers, dog breeders, and others. The perfect car would have a hundred points. So many of them would apply to length, so many to weight, so many to the motor, and so on. Then any given car could be justly classed, and all the cars on the road could be graded collectively as being equal to 50 per cent, 75 per cent, or 90 per cent of the ideal, as the case might be. The physical condition of the track and the grade of track might be similarly indicated. The element of speed could come in on some similar basis. The earning capacity could be likewise shown, and so on to the end of the list of all the elements the street railway man has to deal with. In short, if we had money enough and time enough a plan might be worked out by which any two roads to be compared might be measured up, just as contesting yachts are measured, with the result declared that the boom of one is 2 ins. too long, and must be reduced; that the water-line of the other is 6 ins. short, and accordingly more ballast must be carried, and that when these adjustments are made, still, to be fair, it is necessary for one to allow the other ten seconds' advantage in the race. Everything is possible, if only the time and money necessary to the undertaking are conceded. President Calderwood cautioned the members of the association not to ride hobbies, but the question that has been trotted out for exhibition on this occasion may prove a hobby that will run away with all who venture to test the saddle which it carries. The fact is that each railway manager is up against special problems of his own. No two lines present the same conditions. Each man, therefore, must work out his own solutions, by which I mean very largely, establish units of his own. Everyone can learn something of his neighbor, but the universal unit, by which Montreal can be fairly compared with New Orleans, and New York with Chicago, is a will-o'-the-wisp that it will not pay to run after."

* * *

The report of the committee on a standard system of street railway accounting was in the form of a pamphlet eighty pages in extent, supplemented by a special sheet devoted to a classification of materials and supplies. The pamphlet showed on every page the evidence of the careful and conscientious work which has been given by this committee from the beginning. The report first recounted the conference of representatives of the committee with committees of the Association of Railroad Commissioners, and of the Association of American Railway Accounting Officials, held in New York in July last, the particulars of which were published in these columns some time since. It then set forth the action of the eleventh annual convention of Railroad Commissioners, held in Denver, Aug. 10, last. This amounted to an indorsement and acceptance of the classification worked out by the Street Railway Accountants' Association, after being modified in minor particulars, as agreed by the committees in conference. These changes are essentially three in number. First, substituting the term "operation of cars" for "car service" in expense accounts Nos. 16 to 24. Second, transferring "stable expenses" from account No. 30 to account No. 8, namely, "maintenance of miscellaneous equipment," and, third, putting taxes back into the list of subtractions, that is, among "deductions from income." The report proper was supplemented by a revised classification of construction and equipment accounts, being the classification adopted at Boston by the association and recommended for use, with the changes above noted properly embodied therein.

* * *

The reasons set forth in the report which induced the committee to agree to the treatment of taxes above named, and which it appeared had been a virtual concession to the preconceived idea of the committees of the other organizations which it met in conference, deserve special attention. The Inter-State Commerce Commission established this form of statement a long time since. The steam roads adhere to this rule. The various boards of railroad commissioners have followed the precedent of the Inter-State Commerce Commission, and, while in principle, from the accounting point of view it is not correct, still it is better to conform to established usage. The convention approved of the report of the committee, and therefore for the time being, at least, the mooted question of the place to put taxes is settled. All this brings to mind a little matter in connection with office work, an allusion to which will serve to make clear a thought that is pertinent. The first typewriter that gained a position of favor in the public mind has a key-board that in economy of use is perhaps as much as 30 per cent or 35 per cent below ideal conditions. By the time that a competing machine having a key-board that was ideal in arrangement of letters, and which was scientifically correct, had got on the market the typewriter operators of the country had become so accustomed to the pioneer machine that they measured every new-comer by it. A little detail like 30 per cent or 35 per cent saving in motion of fingers, hands and wrists in operating was not to be considered along side of their blind prejudices. They were wedded to what they knew, and were too narrow-pated to even investigate something else, no matter what its asserted merits might be. The new key-board accordingly was unconditionally condemned. It was doomed to failure from the outset. The facts are that it was ultimately replaced on the new machine by something equivalent to that with which the public had been made acquainted by the pioneer machine. Meanwhile the makers of the latter, in a masterful piece of enterprise, shouted, "standard," and so well have they continued to shout "standard" from that day to this that all the typewriters before the public use a key-board, not ideal in arrangement, but conforming to what was established by the mechanical limitations of the first machine. Unborn generations of typewriter operators, it would seem, therefore, are destined to waste 30 per cent to 35 per cent of the energy expended in their work simply because their predecessors did not know a good thing when they saw it.

The parallel is apparent. It has become "standard" to deduct taxes from income, and therefore it goes.

* * *

The election to honorary membership in the association of H. A. Davies, of Cleveland, was one of the pleasing incidents of the convention, as well also as a deserving tribute to the good work which an able man has performed in the interest of standardized methods. Mr. Davies has recently severed his connection with the street railway industry to become secretary of the National Carbon Company. For two years he served on the committee on standard accounts, and, in a letter, which he recently wrote and which Mr. Duffy read before the convention, he expressed continued interest in the purposes and work of the organization. Mr. Duffy made the motion to include Mr. Davies in the select class, heretofore composed of H. H. Windsor and Edward E. Higgins exclusively, and the vote in support of the same was unanimous.

* * *

Mr. Brockway's report as committee on blanks and forms was a model piece of painstaking work. No less a monument to his indefatigable industry and energy was the collection of blanks which he displayed. These were presented in some twelve or thirteen huge volumes of the scrap-book variety, while a cabinet of the general shape of a safe, shelved off to contain them, represented their resting place when not in use. The safe-cabinet, of wood, was mounted on heavy casters and provided with handles for convenience in moving. The door, hinged in place, was fitted with a good lock. The blanks and forms displayed were casually examined by almost everyone present, and several attempted to go through the collection in a systematic way. Mr. Brockway's comments and criticisms presented at the conclusion of his report were received in good part, and in several instances were applauded. The usefulness of this collection would seem to depend upon the circulating library feature, far more than upon the display at the stated conventions. How the duplicate set of blanks can be obtained for examination by the members was carefully set forth in the report.

* * *

Not a few expressed serious disappointment that the promised paper by Mr. Barnaby was not forthcoming. It was evident that it had been a drawing card in the programme. Several members declared that to hear it and the discussion likely to follow was what brought them to the convention. There was manifested the disposition to discuss the question of "Store-Room Accounts," paper or no paper, but time did not permit. A number of questions were put and answered, among the most important of which was that by Mr. Newman. He inquired how many present kept store-room accounts, and how many did not. The show of hands in response to the president's suggestion of how the question should be answered indicated a nearly even division. This seemed to show that progress is being made in one direction, at least, for, as I recall it, a similar vote taken at Niagara Falls showed Mr. Ross, of Montreal, as almost the sole representative of store-room accounts at that time. It is true that the association is much larger now than at that date, and it is also true that the composition of the convention on the present occasion was more representative than on the former one.

The report of the nominating committee, to which had been entrusted the selection of a ticket to be balloted for, was accepted by a unanimous vote, and the secretary was instructed to cast a single ballot for the officers thus nominated. This vote placed C. N. Duffy in the presidential chair, thereby putting at the head of the organization the man whose capacity, industry and unselfish devotion to the cause he has had so sincerely at heart, have done much to bring the association to its present position of vantage and success. In the dual position of president of the organization and chairman of the committee on standardization of accounts, Mr. Duffy for the ensuing year is likely to find abundant opportunity for continuing the work for which he is so well qualified. The secretary-treasurership remains with Mr. Brockway, who has learned the ropes, and knows just how to discharge the duties of his office to the satisfaction of all concerned.

* * *

The convention finally adjourned without, however, anything having been said about accounting applied to street railway operations. It is true, "accounting" as a term had been frequently employed in connection with various bookkeeping details. No one, however, had seemed to see the opportunity that exists for using what has been done by the association to date as the foundation of an accounting system, which by its analytical completeness shall give the management all those results which it wants, expressed in the simplest possible form, and which by the logical arrangement of its parts, established upon a correct scientific foundation, shall operate with the minimum of clerical labor. Ideas or methods that are in direct sequence to single entry principles predominated for the most part. The relation of the profit and loss statement to the balance sheet of a company was not once alluded to, although several questions that were broached, and which were left open, could have been easily and finally settled in the light of this fundamental principle. No one seemed to think of the importance of modern mechanical expedients and aids in the office—that is, labor-saving devices—and the possibility—much less, the necessity,—of adapting them to use in connection with a scientific accounting system for street railways, in order that the multitude of details existing in this work, evidenced by the classified list of expense accounts, may be handled at the smallest possible cost.

* * *

Those mercantile and manufacturing establishments which have given attention to these problems, although, perhaps some of them are weak in the matters of co-ordinating their expense items, are, as a fact, in possession of far better and and more complete statements of the progress of affairs than are the average street railways of the land. They have the further advantage of accomplishing their results with relatively a very much smaller expenditure than the railways. Like results and like economies, however, are in the reach of the street railways if only they will seek them along the paths which accountants in other divisions of industry have discovered and have blazed for the guidance of their fellows.

* * *

However, comparisons in general are odious, and criticisms of any sort at this time and in this place may seem unkind. Suffice it, therefore, to say, in conclusion, that it is evident, from the work done at Chicago, that the association is making progress. Its members, individually and collectively, entertain broader views at the present time of the work in which they are engaged than it was possible for them to have three years ago or before the association was formed. Altogether, there is hope for the future. The time will surely come when the association will be able to put aside the swaddling clothes of mere bookkeeping classifications, with which it is at present encumbered, and undertake the higher work of investigating and promoting scientific accounting and its economical application to the industry in which they are engaged.

PAPERS READ AT THE CONVENTIONS

Investments in Street Railways, How They Can Be Made Secure and Remunerative

BY CHARLES T. YERKES

The subject you have given me for consideration, namely: "Investments in Street Railways: How They Can Be Made Secure and Remunerative," is one in which I take great interest, and for a very good reason—about all the investments I have are in street railway securities. You can therefore see that my faith is great, for it is from our actions that we are judged.

My experience with street railway securities dates back to a period almost forty years ago, at which time street railways were in their infancy—in fact, you may say, in their swaddling clothes. It was in the early sixties, when the scientific operating of street railways was unknown, and, in fact, not dreamed of. In those days the men were worked from sixteen to seventeen hours out of the twenty-four, and they, as well as the officers of the companies, did not seem to be aware of the fact that this condition could be bettered. The roads themselves were of a cheap character, and, while intended to be permanent, they were far from it, but were equal to the demands of the public and requirements of street railway transportation. In those days even a car register was unknown. The street railways in each city were owned by a few influential persons, generally men of large means, and the stocks and securities of the companies were but little distributed. Few people knew of their value or cared to have much to do with them. To hypothecate street railway stock as collateral with banks was unknown, and it was not until ten years after, in the early seventies, that the banks would look at them. The dividends in the meantime were generally fair, particularly with companies doing a large business in the thickly populated part of the cities in which they were located. To my mind, the chief reason of their unpopularity was that the building of street railways in those days was always opposed by the people in the vicinity of the location, and particularly on the streets where the rails were to be laid. I remember very well the first track laid in the city of Philadelphia, where I then lived. It was the Fifth & Sixth Street line. The people tore up the track at night which the company had laid during the day, and it was not until after there had been several riots and the authorities had awakened to the fact that the law must be sustained, that the company was able to finish its road. The Chestnut & Walnut Street line in that same city was bitterly opposed by the citizens, and everything was done in the Legislature and in the courts to prevent the charter from being granted and the tracks from being laid; and this has been the experience in most all large cities. Consequently, the people who were promoting the laying of street railway tracks were looked on as a sort of "free booters," and their securities with much distrust. To some slight extent this feeling still exists, notwithstanding that there is scarcely a road which was laid years ago that could be taken up to-day without great objection being made on the part of the people.

It was not until the early eighties that street railway securities were seriously considered as popular investments, and since that time their popularity has continued to increase as time developed the great resources which lie within them. The quality of the street railway plants of those days consisted in the kind of track, the condition of the cars and the class of horses which were used. These differed most materially. On some roads it looked as though the cars were never repaired or painted, and the broken-down horses were very much in the majority. Added to that was the uneven rail, spiked to a string-piece, which almost made the rider seasick during a passage over it. Then again, there were other companies where the track was well laid and kept in good order, the cars in good state of repair and well painted, and the horses of the highest class for their work. These two conditions were almost invariably the result of the adversity or prosperity of the different companies, and while the latter class—that is, those that were prosperous—came to be sought as an investment sooner than the other, the anxiety of the public to so invest was never active. But about 1880, when consolidation of different roads came to be more in fashion and the economies produced thereby and also the studious consideration which was given as to how to operate roads, it was more a matter of reality. The attention of capitalists and the people generally was drawn to the stocks and securities of street railway companies, and this condition has been on the increase ever since that time. The fact that great improvements have been made after the horse was relegated to a past era has had much to do with this, and naturally so. The mechanical propulsion of street cars has attracted the attention of the whole civilized world, and the question naturally arose in the minds of those who witnessed these changes, and who had money to invest—"Isn't this a good place to invest our money, and isn't there profit in it?"

The change in the mode of propelling the cars and, in fact, the whole outfit of street railways, has created what might be safely termed a "revolution." To look into the history of all the street railways of twenty years ago and see the changes which have taken place is certainly wonderful. I can see before me a plant that was run with one-horse cars, a driver, no conductor and a pay-box in the front of the car, where the passenger was required to advance and deposit his fare. I see that line changed to two horses and obtaining the dignity of a conductor to collect fares from passengers. That was a great improvement, and then we had straw in the bottom of the cars in winter—not over clean, because we could not afford to put fresh straw in every day, but still this was a luxury,—an oil lamp at each end of the car, which supplied the double purpose of lighting the car and showing the signal on the outside. We went at the rapid rate of 6 miles an hour when we could make it keep on the track. The motion of the car was most agreeable to a person who desired to ride on the billowy waves. We see this changed so that the track was smooth, the straw was taken out, floor always clean, and a stove, giving comfortable warmth placed therein in winter time. This was advanced luxury. We were pleased with all this, except when the snow would come, or the days were hot in summer, when the horses were not able to pull us to our destination.

We see another change—the great power of electricity was brought into use, the horses were gone, and instead of making our 6 miles an hour we would go twice that rate. The oil lamps were removed and electric lamps put in their places. As like begets like, the condition of the cars was improved; cleanliness—always an adjunct of electricity—was substituted for uncleanliness. The districts of the city were expanded, lines were made in the suburbs, creating new towns, improving the property of the people, increasing the amount of the assessment on real estate, until we seemed as though we were living in another world. Aladdin's lamp did not produce any more wonderful changes, and this could not have been done had it not been that the attention of investors, both great and small, had been attracted to the street railways.

And what of the great benefits to the people. Instead of the slow, uncomfortable manner of travel, rapid and easy means are given. Points that could not be reached with the old system are brought within easy access. Everything is better and cheaper. While in days gone by it cost 5 cents to travel 3 miles, with the new improvement four times that distance can be traveled for the same money. Then it cost a person to ride about 2 cents a mile; now it costs ½ cent per mile. Why then, I ask, should not a continuance of this condition be encouraged?

And I now come to the second and most important part of my subject: "How Can They Be Made Secure and Remunerative?" To my mind, security is most to be considered. The remuneration must be brought about by hard and close attention to the corporation. We cannot do much to increase our receipts. They come from natural causes, but we can control our expenditures, and that really, together with knowing where and what to do, is the science of street railway management.

But in regard to making them secure, we must depend very much upon the justice of the people, and the fact that we, as managers, are willing to do what is fair with the public. There seems to be an idea in the minds of many legislators that a street railway is a very simple affair and of very little account. This feeling has been engendered by their knowledge of long ago, and that knowledge has not advanced with the change in street railways. In fact, these changes have come and been accepted as such a matter of course that little attention is given to their worth.

The most important matter in regard to the security of street railway securities is the length of charter under which they are operating. This question is of as much importance to the people as it is to the street railways themselves. The longer time that is given to a charter to run, the greater improvements and the more expensive plant can be operated by the companies. That is to say, it can be made more permanent than if the charter was of short duration, and naturally it would be. If a company has a charter with but a few years to run the improvements will be of a cheap

character commensurate with the length of that charter, and the better the improvements the better it is for the people. Not only for those who own property, but for those who ride and have no property. We see this exemplified daily. Let us ask the question: How many bridges of iron or stone would the steam roads have if their charters ran for only a few years? There would certainly be none, and the speed of trains would be greatly reduced. Years ago 30 miles an hour was considered rapid traveling, with 20 as an average. Now the rate has been run up to more than 80 miles, with 45 miles as an average on fast trains. This latter condition would never have existed if the steam roads had not had charters long to run. Why should not the charters of street railways be equal to those of steam railways? In fact, considering them all in all, they should be longer. The cost of a steam railroad of to-day is not nearly equal to the cost per mile of a street railway, even counting all the appurtenances that go with each. One hundred years has been the time granted in this State for a charter to a street railway, and the municipality grants an ordinance for twenty years. That this was wise or unwise at the time that period was designated, I will not argue, but considering that it was a proper time for what we had in street railways then—rails weighing 40 lbs. to the yard, laid on a wooden string-piece; this string-piece laid on sleepers 5 ft. apart, cars of a cheap class, a lot of horses, good ones, if you please, and a 5-acre lot in the suburbs, where the car-barns were erected,—this practically constituted their outfit. At the end of twenty years, if there was to be no renewal of the ordinance and the charter was allowed to lapse, what would be the loss? The track, considering that it had been kept in good order, would sell for, say 20 per cent of its cost; the cars for about 30 per cent of their cost, the horses for about 25 per cent of their cost, and the real estate, which had been bought by the company twenty years ago, and where in all probability a settlement had since gathered, would sell by the front foot, realizing without doubt twenty times as much as it had cost. There, you see, there would not be much loss if this road had to be given up. But what are the conditions to-day? The street car tracks are laid with heavier material than that used by the steam roads, the power-houses cost hundreds of thousands of dollars, where the old structure cost but a few thousand; the electric plant on the cars and in the power-houses and the wires and poles cost immense sums. So that it can truly be said that the electric plant cost more than ten times as much as the horse-car plant. If, therefore, it was right to give a horse-car plant a charter for twenty years, the electric plant should receive a charter for 200 years and city ordinances should correspond.

It has been argued that if grants were made extending over a long period of time, other means of transportation might come into existence and these charters would interfere with the adoption of these improved methods.

Let us suppose fifty years ago perpetual privileges had been given to operate exclusive omnibus lines in this city, or privileges of the same character had been given to operate ferries across the Chicago River. What would they be worth to-day? Long ago the charters would have been forfeited, simply for the reason that improved methods had rendered them worthless.

But while I feel that the Legislatures should treat the street railways fairly, I also feel that the street railway companies should treat the municipalities and States in the same spirit. I believe that a fair amount of the earnings of the companies should be given to the municipalities in which they are located. There is no doubt but that the street railways are of great benefit to these municipalities and to the people generally and to the property owners, but at the same time it is my opinion that a spirit of liberality should be engendered by the street railways toward the municipalities, for the reason that it is through the municipality that they are permitted to transact their business. It is a mutual benefit, with the burden on the corporation. There is no doubt but that the extending of the lines in a large city is a great hardship to the railway company. There is little money to be made out of them for years, and while the company is waiting, the property owners and people are being benefited. The very mention of the fact that a line is to be extended in a certain district causes advances in the value of real estate, and these advances are emphasized when the extensions are really made. There is nothing that has added so much to the health of the inhabitants of a city as the extension of street railway lines. In this city the tenement house district, which would have been a perfect pest-hole, is scarcely to be found. The prairies have been covered with street car tracks, which forces the opening of streets. Cheap lots and cheap homes for the working people and the poorer classes, as well as the well-to-do, are everywhere in evidence. While there may be efforts to influence the people against street railways, they cannot but see these conditions, which are so plainly visible to them, and seeing them, fail to properly appreciate them.

I believe in educating the people, of whom the legislators are the representatives. Every State wherein there are large cities, which necessarily have important street railways, should have a commission appointed to ascertain the condition and requirements of this industry. The commission should be appointed by the Governor of the State, and should be composed of intelligent business men of first-class standing, who are not interested in street railways. Under no condition should a person holding office, or who is ambitious to do so, be named. A man of this character is never to be trusted in any affair where courageous opinions are expected. The reports of such committees should have great weight with the legislators.

I believe that all corporations which receive their life from the commonwealth should be subservient to that commonwealth, that there is nothing in their formation or general business which should not be reported to the proper authorities and be subject to investigation. I believe that the law should provide that an intelligent commission be appointed by the Governor of the State, in the same manner as is now done in this State in regard to the commissioners of the park system. The duties of this commission would be to see that the laws concerning street railways are carried out and that the companies have the protection to which they are by law entitled. The commissioners should have terms of fifteen years, so as to insure their becoming experts, and receive such salaries as would enable them to live well and take care of their families in a good manner. They should understand, when appointed, something of the street railway business, and as years pass by their knowledge would increase, as also their worth. They should have the power to dictate to the railway companies where new roads should be laid, if at all, and also the kind of new improvements to be used when a railroad contemplated making any change in motive power. They should have the power to regulate the devices to be used for saving life and preventing accidents. With an intelligent, honest commission of that kind, street railway managers would be made more comfortable, the people would be benefited and the securities of the corporation would be more solid. The advice of these commissioners would be sought, and the advice of such men with the experience and knowledge they would naturally have, would be most valuable to any railway manager. Their reports would be explanatory, and much of the ignorance regarding street railways, which is fostered by our enemies particularly in this part of the country, would be done away with.

To make securities more secure we must have these different matters fully understood. We must do our business in a straightforward manner, with due consideration to the public, who are our patrons, continuing to increase facilities as opportunities offer, and adopting the most improved kinds of transportation which experience teaches are proper. And last, but by no means least, holding with the kindest regard our employees, who are faithful to us to the end, that there may be perfect harmony between them and the management, and seeing to it that our corporations are able to earn honestly a fair remuneration for the money, time, experience and labor that have been spent upon them.

Train Service and its Practical Application

BY IRA A. MCCORMACK

It is an unquestioned fact that a well arranged train service is as essential to the commercial success of a street railway enterprise as is expert management of the power-house and equipments, the use of economical machinery or any other vital detail, and it is perhaps one of the hardest problems that street railway managers have been called upon to solve.

In presenting this paper the writer would not wish to be understood by the members as presenting a sovereign solution, but rather as submitting methods which he has found to be useful in cases that have come under his observation. The conceded fact that all discussions must have a nucleus and that the experiences of no two persons are alike, whereby the natural law obtains, that one is certain to learn something from another, must be the apology for what follows.

In mapping out the train service of street railway systems in a large city the problem will be found very intricate. Some lines have continuous traffic at almost uniform proportions at all hours of the day; some have rush hours at morning or night or both; some have hours of over-crowding at more frequent intervals, and with some the traffic is exceedingly irregular. There is the passenger who rides but a few blocks; there is the through passenger and transfer passenger. The problem is further complicated by the location of parks, places of amusement, shopping or residential districts, branch lines, and the summer and winter seasons, and it is perfectly evident that no general methods can be laid down.

The problem naturally divides itself into two parts; first, the ascertaining of the conditions of traffic which are to be met, and second, the means for meeting these conditions in the best possible manner.

No matter what the character of the service may be, suburban, excursion, or local, there is one ideal condition to be aimed at, and that is that each car be full of passengers. If there be less than a full car the equipment is not run to best advantage, and fewer car miles would render the same service, while if the car is crowded, the traffic of those who dislike a crowded car may be lost and the management is likely to be criticised unfavorably by the public and press. It is important, therefore, to determine with as much accuracy as possible the traffic conditions, that is to say, how many of the public want to ride, where they want to ride, where they wish to take the car and where they wish to leave it.

For convenience in making specific illustrations and also to enable the discussion of different conditions as far as possible,

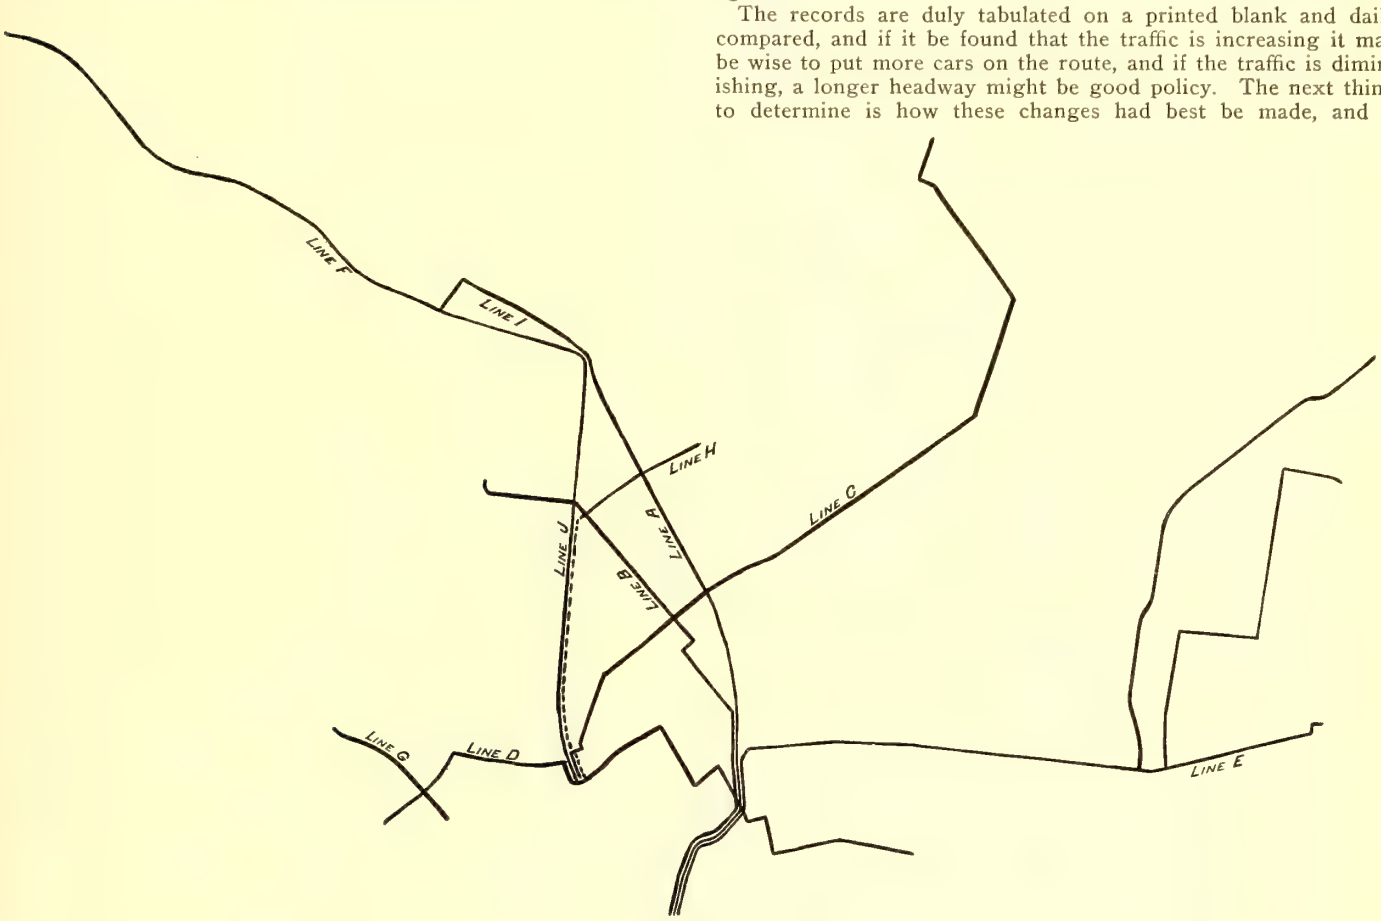

DIAGRAM OF LINES SERVED

the following different characters of service may be cited:

Line A.—A line of heavy traffic in shopping districts in close competition with elevated railroads.

Line B.—Doing a heavy traffic in residential districts without competition.

Line C.—A cross-town line serving as a transfer system to connect other lines together and add to their attractiveness.

Line D.—A cross-town line connecting with centers of transportation, such as railway stations, ferries and the like.

Line E.—An excursion line, half of which is residential, on which the excursion traffic varies with the season.

Line F.—A suburban line of considerable length and operated at moderately high speeds.

Line G.—A line not over remunerative and operated for such reasons as public or press opinion, or hope of its future value.

The conditions that will obtain on these various lines are obviously widely different. It will be first necessary to evolve a method of determining what these various conditions are.

At the start, the manager is as helpless as an outsider. He can merely generalize and deduce a time table which to his best knowledge of the system will fit the conditions, but having thus formed an existing time table the knowledge of how it operates and how it can be corrected is rapidly and easily acquired by the best of all methods, that of practical experience. In collecting the necessary data a method which the writer has found of value is to provide each car conductor with a blank which contains spaces on which the number of passengers carried on the car between the termini can be conveniently listed and totalized. This slip is conveniently arranged so that on it are registered the following data:

1. Name of operating line.
2. Run number as per time table.
3. The date.
4. The time due to leave terminal.
5. The actual time of leaving terminal.
6. Passengers carried on down trip.
7. Passengers carried on up trip.
8. Tôtals.

This slip, signed by the conductor, is turned into the proper office. This, of course, gives general information as to the traffic. It shows whether it is heavy or light, whether it is falling off or increasing, whether it is increasing on the down or up trip, and also gives a check on the register. This information is usually collected in one way or another by almost every street railway management.

The records are duly tabulated on a printed blank and daily compared, and if it be found that the traffic is increasing it may be wise to put more cars on the route, and if the traffic is diminishing, a longer headway might be good policy. The next thing to determine is how these changes had best be made, and if possible to ascertain the specific reason for the increase or loss in traffic. To do this the inspectors are provided with blanks and are sent out on the line. Various points are chosen, and at those points the passenger record is very carefully taken. This slip provides for the record of the following data:

1. The place of record.
2. The name of the line.
3. The date.
4. The observed headway.
5. The number of passengers on the cars at points of record.
6. The fares rung up on the register at record points.
7. The totals.
8. The general average of these quantities.

On the back of the slip the inspectors find the following instructions and queries to be answered:

Note. Inspectors will be careful to show correct count. Make report plain and clear, but use as few sheets as possible.

If record of but one line is being taken, show the name at top of page.

If record of several lines is being taken, indicate name of each line in blank space at head of column.

If conductors are found short, give conductor's badge number and state particulars.

Give any and all information of this report that will prove of value in permitting change of headway and condition of cars, etc., to improve the service.

Is the headway well maintained?.....

Is there enough or too much service at any hour?.....

Are cars running to proper terminals to accommodate the public?.....

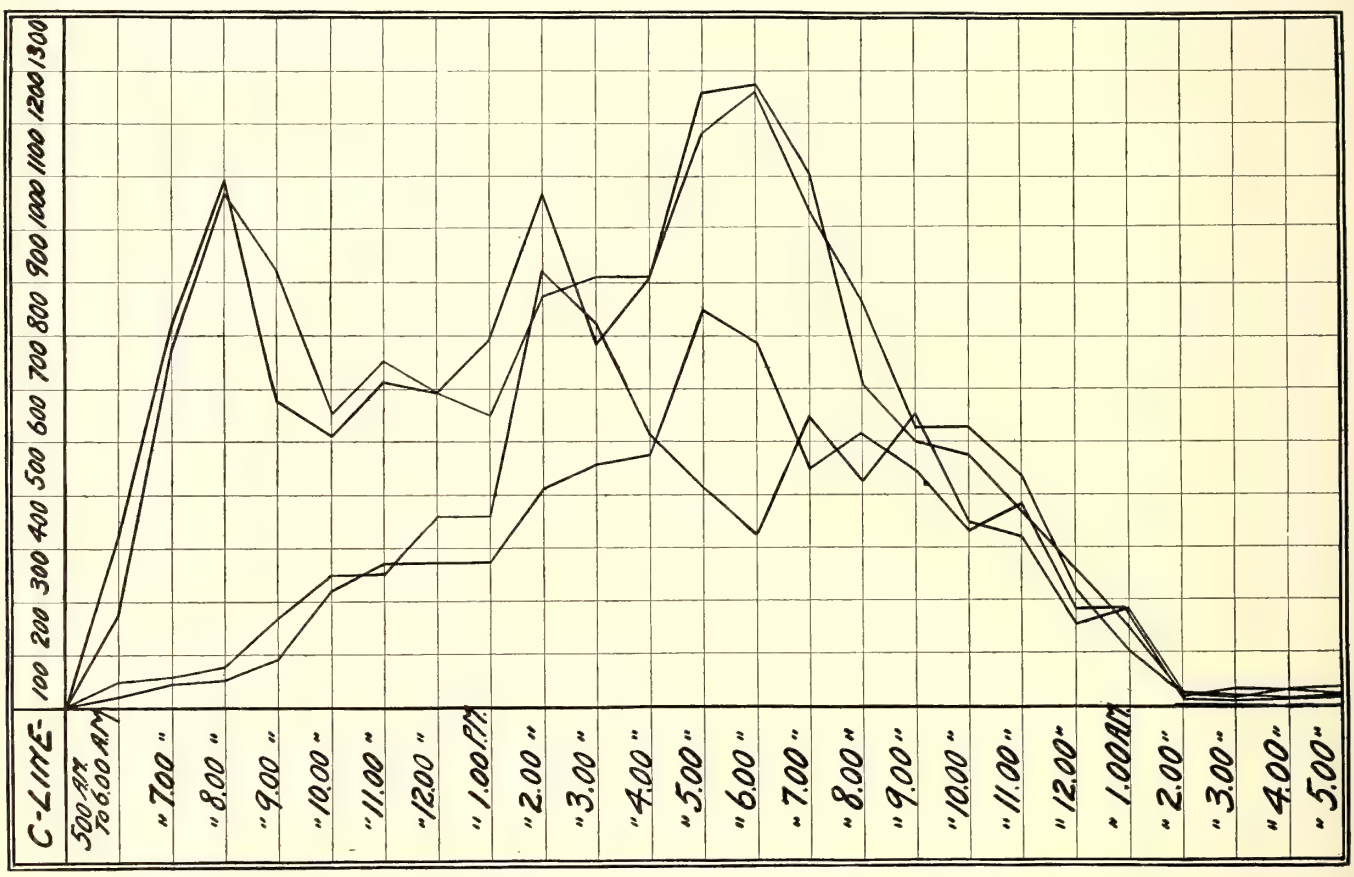
General condition of cars.....

Conductor found short

Car No. Conductor No. Particulars.

It is sometimes instructive to plot the results in the form of

curves. Suitable section paper is selected and the number of passengers per hour are plotted as abscissae, and the hour of the day as ordinates. This gives opportunity to examine a large number of figures at a glance, and is sometimes useful in drawing general conclusions.



These reports give much valuable information. They show the average number of passengers on the cars at the point of record, thereby determining whether the cars are overcrowded or not. It gives the total number of passengers carried up to the point of record and an approximate idea of where they left the car. If the traffic on the line is irregular it shows in a measure where it is heavy and where it is light, according to how near together the points of observation are selected, and it further shows the exact time at which these traffic conditions obtain.

In order to obtain trustworthy results it will be necessary to take these records for some time, possibly for a week, for a single record might be completely misleading, because of condition of weather or a yearly Sunday school picnic or smilar flush of traffic not likely to be repeated. It remains to be said, however, that as a rule weekly records check very closely. Having certain rules, which long experience has shown are almost imperative. There are certain traffic conditions which are temporary, and others which are permanent. There are competition conditions, and in many ways there is much else besides these records to consider.

For instance, I have classified those who travel on street cars as follows:

1. The workers, who travel from 5 to 7.
2. The clerkers, who travel from 7 to 8.
3. The bankers, brokers and proprietors, who have sometimes been facetiously termed the "shirkers," who travel from 9 to 10:30.
4. The shoppers, who travel from 10 to 12.

The greater part of these people remain in the city, coming back in one grand rush hour, which begins between 4 and 5, and reaches its culmination point a little after 6, and sometimes lasts until after 7. Then the theater and places of amusement begin to influence the traffic, which swells in the direction of the metropolis till a little after 8, and outward again, from 10 to 12. The regular night hawks, who take care of the traffic

METHOD OF TABULATING RESULTS

obtained a fair average of the number of passengers to be carried between two points, the proper headway between these points can be computed, and the next question that obtains is how to get this headway.

It may be advisable actually to put on more cars, or again it may be that the increased traffic occurs between such points on the line when it would be advisable if possible to loop down upon this section a few more cars from some adjacent line. This would be desirable especially if at the corresponding section on the adjacent line the headway was found to be too short.

So far, the method seems to be a simple mechanical process in which the steps for remedy are as obvious as in a station test. It is unfortunate for the sake of simplicity that this is not the case. In making a station test the diagrams and curves obtained invariably show the condition of the machinery or apparatus tested. The curve traffic above described would show the condition of traffic were it not for the fact that the public and many local conditions, which would seriously effect the traffic, must be considered. As an instance of this, when the information is being gathered to plot out the curve traffic, a fair, festival or entertainment of some nature may be in progress, which would cause traffic to go in the direction of the entertainment. Therefore, the curve traffic without considering the local, and all traffic conditions, might lead to an erroneous conclusion. The maker of a new time table must know the lines, root and branch. There are of the city between 12 and the early hours of the morning, it is usually wise never to disturb.

It is sometimes possible to meet the traffic conditions on a line without increasing the car mileage, by simply changing the character of the cars which are running upon the line. Long cars with double trucks are advisable on through traffic, and it should be the aim of the manager to run them at the times when they will collect through passengers. Short cars should be run for the convenience of short riders, and if it be found on any line that at a certain hour of the day a large percentage of short riders take the cars between certain points, a little ingenuity in adjusting the long and short-car service may frequently accomplish a great deal.

On Sundays and holidays the traffic conditions change radically. On some lines the traffic falls off a great deal, and on others it becomes exceedingly heavy. On lines running to places of outdoor amusement, such as parks, beaches, race tracks and the like, it is well to watch the weather, for it is obvious that if the day is pleasant the traffic will be much heavier than otherwise.

The best men are picked out to run on the lines of heaviest traffic, in order to have the benefit of their experience in handling the public, knowing that they will be more safely handled and more convenient service given them than if a poor class of motormen and conductors are operating the lines of heaviest traffic. A street railway manager would—were it in his power—locate

amusements and entertainments upon the best built and best equipped lines, for it is on these lines that the best service to the public is given.

Of the last statement it may well be said that the duty of a superintendent may be divided into two equally important portions. First, the arrangement of the system for the good of the company and public, and second, for the good of the men. These duties are not all incompatible, although by some this has been thought to be the case. It is very important for the company to have a force of competent, well satisfied and not overworked men. I contend that a man earning $40 a month and who is satisfied with his surroundings and conditions is a better employee for any company or corporation than a man who is earning $500 a month and who is discontented and dissatisfied with the surroundings, and, on the other hand, it is important for the men that the company shall be prosperous, for otherwise there will be less regulars and more trippers.

It frequently happens that the time table of a road can be corrected to meet the conditions of traffic by delaying the cars at certain points and increasing their speed at others; thus, for instance, it has often been found beneficial to instruct the motormen to stop their cars at junction points and wait for the car on the cross road, in order to exchange transfer passengers, or perhaps to wait a stated time, say two minutes, and then to proceed. It is plainly to the advantage of the road to exhaust all such devices as this before actually running more cars to meet the increased conditions of traffic. If more cars are actually to be run the question should then be considered as to what kind of cars, that is to say, long cars or short cars, and if the road be a main artery receiving the traffic of several branches or cross lines, whether these cars should be main line or branch cars, and if branch cars, which branch.

From a practical knowledge of the conditions, and from the data as has been outlined, a new time table can be made up, but it is not to be expected that it will prove of lasting value. The traffic must be carefully watched; the conductors' reports carefully compared, and whenever an increase or decrease of traffic is shown, the advisability of sending out inspectors with passenger record slips should be at once considered.

Traffic may be increased temporarily, particularly in manufacturing districts, when some large manufacturer will put at work a large number of men, or may be decreased temporarily by the closing down of an industry, the workers of which industry were mostly patrons of the road. By the use of conductors' slips the superintendent will be at once advised of these changes.

These conditions show the necessity of an intimate knowledge of the entire system. The management, however, should not deceive itself in case mere adjustment is not successful. If the cars are still crowded, in spite of all manipulation of length of car and variation of headway, more cars should be put on.

However instructive it may be to make general remarks on these matters, specific cases and their solution are always interesting, and to provide this the writer has selected from his records a number of cases illustrative of different conditions which may be of interest to the members.

A practical condition that obtained recently was the case of a line, H, which formerly had its route down another line, J, to a ferry terminus. The inspector's report showed, first, that it was necessary to increase the service on a certain intersecting line, B, and second, that a great many passengers from line H transferred to line B, in fact, more than continued down line J. When these facts were known the solution was obvious. The traffic of line H was cut off from line J and sent down line B, thereby giving the desired service, avoiding the transfers, and only very slightly increasing the mileage and not at all increasing the number of trips or equipments.

Another interesting case may be cited of a line I, a short line running from the terminus of a main artery upward into the country. The traffic was found to be so great that it was necessary to diminish the headway. This was done by running some of the main artery cars over line I. This had the effect of slightly increasing the car mileage, but did not require any new equipments and gave through service from terminus of main artery to the further terminus of line I, which was beneficial.

Another interesting case is that of a cross-town line, C. This line carries through passengers to its terminus and also acts as feeder to the various lines which it crosses; therefore, in one portion of its length the traffic is exceedingly dense and the headway must be correspondingly short. This object is simply attained by running short lines which travel back and forth through the sections of heavy traffic, and the through service is run on a headway suited to fit the conditions of the more extended portion of the line, and also helps to diminish the headway in the more heavily patronized sections. Line D—the other character of cross-town line—is also very interesting. The line starts at a railroad terminal and distributes incoming passengers to their destinations. It passes through a large factory district and transfers a great many passengers to other lines crossing it at different intervals; it also traverses shipping districts and gives access to the docks. It is essentially a day line, and it has been found that in such a case the traffic has been met to best advantage by a practically uniform service. This is a unique exception in railway work. As a final illustration we may take a line, E, on which the traffic varies. The first section of this line is residential. The last is excursion. In the summer season the headway on the residential district has to be quite short to accommodate both classes of traffic. In the winter season the conditions are met by cutting the line in two and running a suitable headway through the residential district and a shuttle service of a few cars over the excursion section.

The street railway manager will easily see that these methods are typical, but by no means exhaustive. There are many methods of manipulation, and the opportunity for ingenuity on the part of the maker of the time table is exceptional.

Besides ascertaining the traffic conditions on the various lines it will be found necessary to pay strict attention to the actual management of the system, in order to obtain the train services that may be desirable.

In the first place, the power-houses must be located at such points as to conduce to equal distributions of voltage. Low voltage on any line means slow time, no matter how good the motorman or the equipment, and everything that may produce this trouble should be carefully avoided. Every precaution must be taken in the operation of the power-house to prevent shutting down. Power-house attendants often become careless and are slow in replacing a circuit breaker when it is blown out, not realizing that they may be wasting the time of as many as 1000 persons. The writer has known cases where the circuit breakers of two different lines were thrown at one time. The man who watched only noticed one of them, and, replacing that, failed to close the other, resulting in a most serious delay to the line which it supplied. It has been suggested that a switchboard should be equipped with an automatic device, which, in the event of a circuit breaker being thrown, would close a circuit and cause the ringing of a large gong, which would show to the switchboard tender or employees of the power station, whose duty it is to see that the circuit breakers are kept in, that there is some breaker or some line, which is not furnished with power. In this and in scores of other ways the station attendants are responsible for the accuracy of the train service in fitting it to an approved schedule.

There are also other cases which are incident to the power-house, and are in no way attributable to the men in direct charge. One of these which may be mentioned is false economy in purchasing a poor quality of coal, which, in spite of all that can be done, allows the steam pressure to drop and does not supply the engines with sufficient energy. Similarly, the use of poor oil may allow important bearings to become heated, which results in crippling the line or overloading other machinery, thereby causing a reduction in voltage, or it may be that the headway for the time will have to be lengthened, thereby departing entirely from the approved schedule. In short, everything must be done at the power-house to provide at all times sufficient current at a sustained voltage at the cars. Without this, any schedule however accurate and elaborate will fail in carrying out its object. The details of producing such service are so voluminous and have been so ably discussed by other writers that anything further than the statement of the condition would be superfluous here.

The track and overhead construction should be secure and serviceable. It is obvious that a good track is essential to good, comfortable riding, which will please patrons. Special work should be maintained in first-class shape and renewed promptly. It may be mentioned that it is not a wise practice to allow work of this nature to become worn to its last stages before steps are taken for its renewal. An order for special work of necessity cannot be filled promptly, and it may easily be that if there is delay in placing the order, the old frogs and crossings will become very much worn, cars will be derailed, axles bent or broken, motors dropped, and, aside from the actual expense of repairs and maintenance, the train service, which is the prime factor, will be interrupted.

The writer's experience has been that considerable trouble has been encountered in maintaining a train service by reason of the spread of the rails and consequent accidents and delays. Where the traffic is at all heavy this accident is very liable to occur unless the rails are bound with tie rods.

Both the track and the overhead construction should be of the very best. A broken trolley wire is even worse than a disabled truck, for it may tie up not only one car but a whole section, and anything which will minimize the liability of wires coming down is advisable. In order to preserve the train service the work of re-

pairing the overhead construction should be performed at such times as will least interfere with the service. This is usually at night.

In order that overhead maintenance can be performed to the best advantage, emergency stations should be located, each of which is assigned to certain territories. The station covering the heaviest travel should be able to reach its outer boundary in eight minutes, while in suburban districts the furthest limits should be reached in from fifteen to twenty minutes. The construction wagons should consist of an extension platform, from which the overhead work can be reached without standing the wagon in the trackway.

Track and overhead repair men should be impressed as strongly as possible with the fact that in making their repairs it should be done in such manner and at such times as will interfere least with the operation of the cars. The judgment of some track and overhead repair men cannot always be relied upon to carry out this injunction. Train service is often interrupted by track and linemen, in making repairs to the track and overhead system, by attempting to make too permanent repairs at a time when the service is heaviest and should be interrupted least, when a temporary repair would have done just as well until such a time as the service was light and permanent repairs could be made without interruption to the service.

The writer knows of one particular case where the ear of a double pull-off on a curve had become so bent and out of its proper position that when the trolley wheel was riding under it the trolley would come off and one of the arms of the pull-off and the bent ear would serve as the prongs of a boot-jack, the trolley harp and wheel catching in the arms of the pull-off and doing one of two things, pulling down the overhead work or pulling the trolley pole from out of its base.

It is a common fault to pay too little attention to the application of guy wires on curves, and serious delays due to failure of overhead construction on curves are very frequent. Sometimes the work is satisfactory for short cars, but on long cars the motion of the trolley, being somewhat different, is likely to throw the wheel off the wire. Frogs should be placed in the overhead work where the lines diverge at a point that will insure the trolley wheels following the desired route.

Another and exceedingly important feature of good train service is the selection of motormen and their instructions in running the cars. Many elaborate papers have been written on how to run a car to use minimum current and to produce minimum wear and tear on the equipment. These instructions, while ingenious and accurate from a technical point of view, and possibly of wise application in small country roads, are not at all suited to the heavy traffic conditions which obtain in large cities.

In such cases the most important duty of the motorman is to make schedule time, keep a sharp lookout for passengers and avoid accidents. It is interesting to note in this connection that the best motormen are often men who can neither read or write, and are found among teamsters, drivers of horse railways and the like. These men are accustomed to do implicitly as they are told. They are accustomed to watch the street carefully and keep good track of vehicles and persons, by which means they avoid accidents and secure passengers.

The semi-technical man, who is "learning the business," makes the worst motorman of all. His mind is more active, he is interested in the performance of his motors and equipment and neglectful of his primary duties as motorman. He is always on the lookout to take note of matters which, though they may be valuable to him in his personal advancement, are entirely foreign to his duties. More than that, he is a dissatisfied individual, looking for better employment in the near future, and for that reason he is not inclined to learn his business of motorman thoroughly, regarding it as scarcely worth his while.

Of course, it is necessary that the motorman have certain instructions with regard to managing the controller. He should know that it is not advisable to give the motors too many notches at once; that he should, wherever possible, allow the motor to gain speed on one notch before passing to the next; that he should run the car on certain notches as far as possible, and that he should not allow the controller handle to dwell on spaces between notches, but it is not at all necessary for him to know why the motors are more economical at full series or full parallel or just what misconnections are likely to obtain if the controller is run between notches. It is sufficient that certain things must be done and that certain other things must not be done.

It is, nevertheless, a fact that a good motorman will run a car with less energy than a poor one and still maintain schedule time. A good deal of this may be ascribed to the careful use of the brake. It is necessary in making a fast schedule with many stops to shut off the power and use the brake almost before the car has gained headway. This frequent use of the brake is a temptation to many motormen to keep the slack of the chain taken up, so that a slight pressure on the brake handle will put the brakes on hard. This keeps the shoes in contact with the brakes at all times, giving excessive friction and loss of power. A good motorman will coast his car as much as possible when the schedule will permit it. It is certainly advisable to keep accurate record of the way the motorman manages his equipment, but inferences must not be drawn too hastily from such records. If a motorman in charge of an equipment wears out his brake shoes rapidly and comes in with the regulating resistances sizzling hot, the schedule on which he has been running must be considered. If he has been on a fast schedule with many stops, and has followed it closely, the condition of his car signifies very much less than would be the case if he had an easier run and had failed to make schedule time. In forming an estimate of the qualities of motormen, train inspectors, conductors, and particularly of officials having men in charge, the writer has found first impressions to be exceedingly valuable. The well-known saying that the sober second thought is seldom wrong is not always correct. Judgment should, of course, be suspended until the second thought has been well considered, but the first thought may be right after all. It certainly has the advantage that it usually represents the only impression that the majority of people will consider, and hence may be the popular impression, which in street railway work at least must be catered to.

After all has been said and done with reference to the manipulation of train service it is interesting to know what results may be expected from good work in this department, and to exemplify these matters, the writer again cites from his records cases which he ventures to think will justify the statement that the matter of train service is of great importance.

It is not always easy to record the income of a line; for instance, a passenger may take line A, and ride on it for 100 yds. and pay in his fare simply and solely because he can obtain a transfer on line D. Line A gets the credit on the books and line D, which actually performed the transportation, carries the debit side of the account. There is nothing on the transfer to show whether the passenger rode a longer distance on line A than on line D or vice versa. To be strictly accurate, the fare and the expense should be charged to each line in proportion to the distance the passenger was carried on each, and while attempts may be made to equalize the accounts, in this respect absolute accuracy cannot be hoped for. The results are therefore submitted subject to this criticism and are the best that can be obtained under the circumstances. The following examples are taken from monthly comparison sheets. These sheets are made up from the reports of the conductors, the inspectors and the books of the company, and comprise the following data:

1. Receipts.
2. Total passengers.
3. Mileage.
4. Receipts per car mile.
5. Number of trips.
6. Receipts per trip.
7. Average length of trip.
8. Average number of cars per day.
9. Average mileage per car per day.
10. Time table cost.
11. Columns for the record of increase or decrease of these quantities over the same month in the previous year.

If the comparison sheet shows increased receipts, diminished mileage, diminished number of trips and diminished time table cost, the result must be ascribed in a large degree to the management of the train service. I may cite as examples the following:

From a monthly sheet on a certain line the increase in gross receipts was $3,586, the decrease in mileage was 18,920 miles, due to the substitution of short lines for longer ones. The decrease in time table cost was $1,612, representing an actual increase in revenue to the road of $5,198. This amount as a monthly incentive for ingenious manipulation of the train service is certainly attractive. On another line almost as large the increase in gross receipts was $13,765. It was, however, accompanied by an increase in time table cost of $1,902, representing a net gain of $11,867, certainly a wise investment for the added expense. The large gain in gross receipts was due to changing of the terminus to a better center of distribution. This manoeuver not only filled up the empty cars that were running formerly, but necessitated the running of additional equipments.

Another case may be cited in which the gross receipts showed a loss of $7,087 and the time table cost a decrease of $2,814, representing in total a loss of $4,273, as compared with the same month of the previous year. This, while not so pleasant for directors' contemplation, is very important to know. The reason for this was found in the fact that a number of large factories on the line had been shut down. It might have been due to local conditions or that the train service could be improved.

In like manner a yearly comparison sheet can also be drawn

and careful management can often in a well established road increase gross receipts or largely diminish time table cost. From such a sheet involving a yearly total from thirty-seven different lines may be cited an increase of more than 10 per cent in gross receipts and a little over 1 per cent in time table cost. The receipts per car mile showed an increase of 5.8 per cent. The receipts per trip were increased 16.5 per cent. The average mileage per car increased 15½ per cent, whereby about 144,000 trips and the incident expenses were saved.

Such figures as these on a system in which the building of new lines had been relatively small can hardly be ascribed to growth and extension, and could scarcely be obtained except by running the cars longer distances and by suiting the public taste, whereby larger loads of passengers were carried, or briefly and in other words, by improved train management.

Construction and Maintenance of Street Railway Tracks

BY EDWARD BUTTS

The construction and maintenance of street railways involves two words, construction and maintenance, which are inseparable in considering a street railway enterprise in its relation to capital.

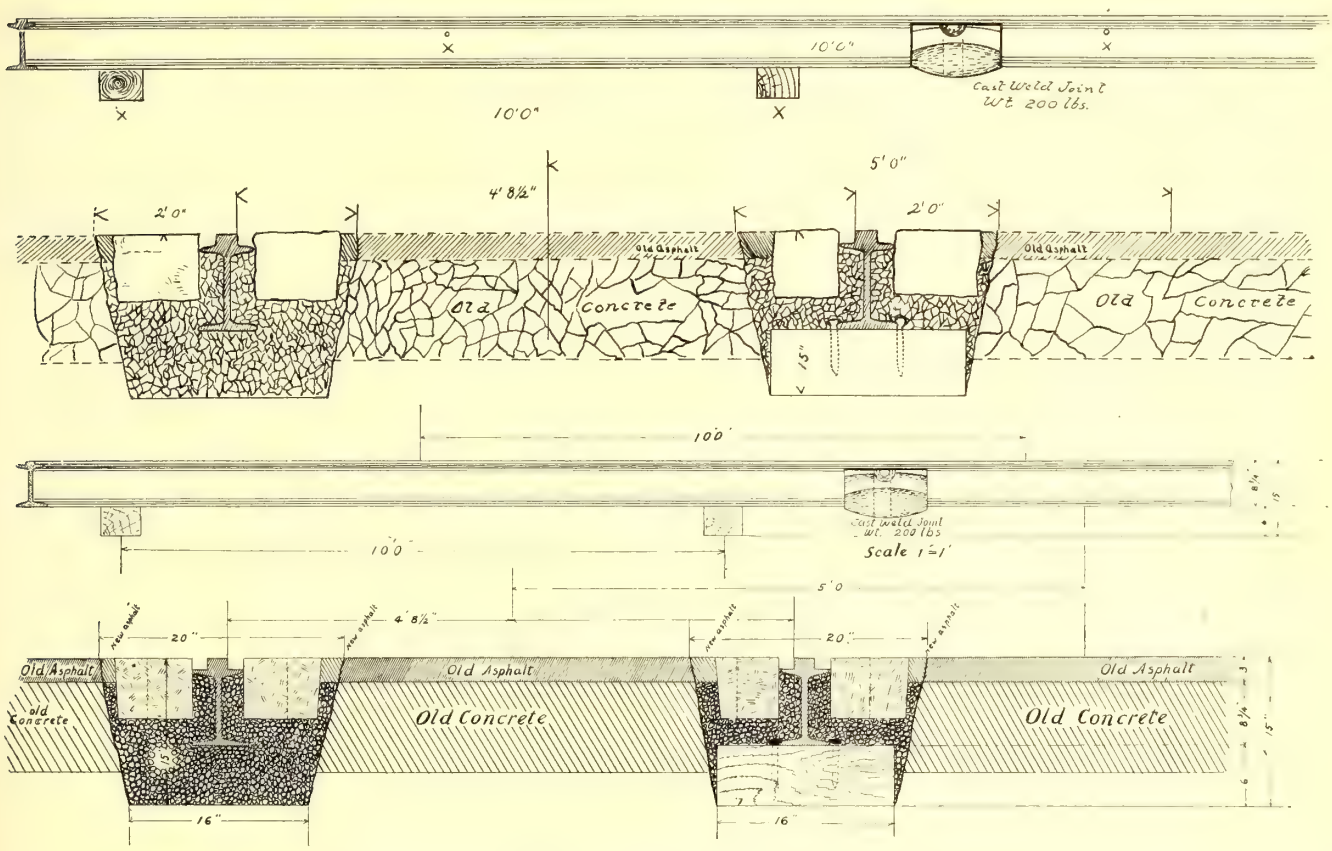
Is the street railway to be built for temporary purposes? Is it to be built simply to float on the market or to turn over to our successors and assigns, or are we to build a street railway to endure to the extremity of the present advanced stage of science, speaking particularly of the use and durability of materials? The latter view will be accepted in preparing this paper.

In street railway construction, the first thing to do is to consider carefully all the local influences which may become factors in maintenance, or involve future changes, and so considering the subject from this fundamental position, the question naturally divides itself into urban and interurban street railway construction.

It is desirable in all cases to construct the street railway in such a manner that when it becomes necessary to reconstruct the interurban portion the termini shall need the same attention at the same time, and as a general proposition it may be said that the urban end of a line is the governing factor when durability is considered. The reason for this is, of course, because of the concentrated travel there.

For the present, then, we will consider urban roads from a standpoint created by practical experience and expenditure of capital.

The rails should be not less than 6 ins. in depth, with a width of base equal to the exposed upper surface. Where streets are paved with asphalt and a stone toothing course placed adjacent to the rails, the rails must be at least 9 ins. in depth, in order that the base may be securely imbedded in the concrete below. Rails should be center bearing, rolled in 60-ft. lengths and so handled that they will be perfectly straight when placed in final location.

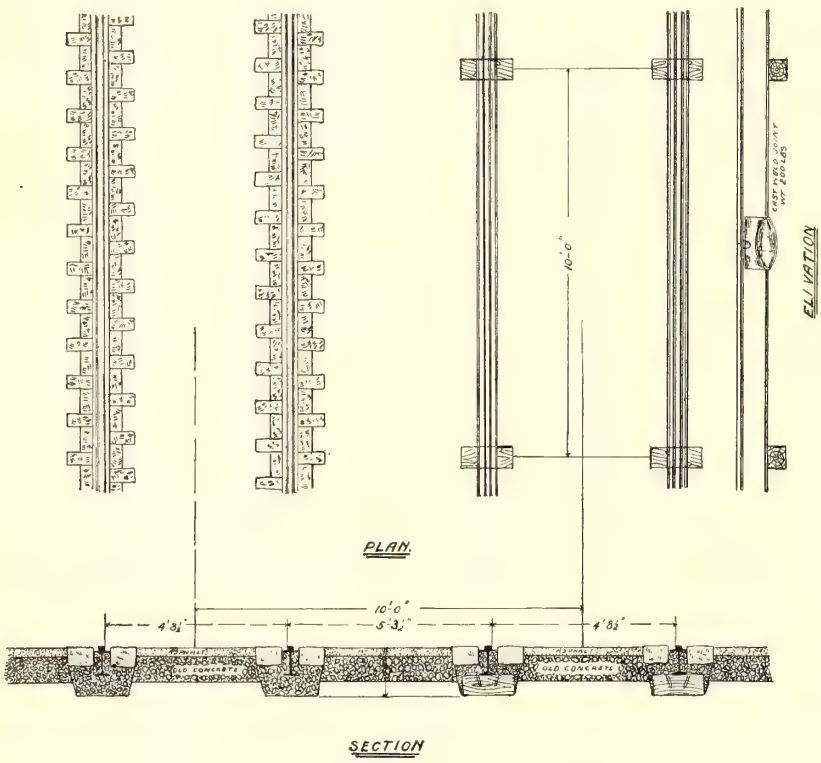


Tie-rods 1 in. in diameter should be placed 6 ft., center to center, along the line and supplied with hexagon nuts, which, when in place, should clamp the rails securely on both sides. The tie-rod threads should extend far enough from the rod ends to allow the rod to be put in place without bending it. The theory of this rigid tie-rod is that the street traffic and pressure on the outside of the rails should be provided against, as well as the car thrusts on the inside. The top of the tie-rod should be placed half way between the top and base of rails to better accommodate the paving, especially if the wearing surface is brick or stone.

For rail foundations a trench should be dug, 20 ins wide on top, 16 ins. wide on bottom, and deep enough to be 6 ins. below the rails when the latter are at the established grade. In this trench, at 10-ft. intervals, should be placed wooden blocks, 8 ins. x 10 ins. x 16 ins., to which the rails can be securely spiked. These blocks serve to hold the rails in position while they are being laid and tamped to surface, the joints being held in position by temporary splices.

After nicely gaging, aligning and surfacing the track, the trenches should be filled with concrete, bedding the base of the rails up to the bottom of the proposed paving. The concrete, which is placed in the trenches around the rails, should be composed of crushed stone, measuring not more than ½ in. in greatest dimension, with Portland and domestic cement, and sand, mixed as follows: Two parts sand, one-half part Portland cement, one-half part domestic cement and five parts crushed rock, all by measure. Great care should be taken to get the mortar flushed close against the rails and to bring it full up under rail trams. The concrete in the trenches should be allowed to set about six days; this time, however, depends upon the condition of the atmosphere, as the concrete will set much more rapidly in warm than in cold or chilly weather.

The concrete for paving foundation may also be composed of one part domestic cement, two parts sand and four parts broken stone, by measure, the broken stone to be not larger than 2½ ins. in the greatest dimension. All concrete should be thoroughly tamped until the mortar flushes to surface.



After the concrete has set, cast-weld joints should be poured at all joints, including those of the special work which may be needed.

ELEVATIONS AND SECTIONS OF TRACK CONSTRUCTION, KANSAS CITY

The cast-weld joint on 80-lb. rails should weigh 150 lbs, and on 100-lb. rails, 200 lbs., the metal cast about the joint should be composed two-thirds of pig iron and one-third common scrap iron. The metal should be heated to a bright yellow temperature and each joint formed with one pouring. The depressing clamps should remain in place for at least one hour after the pouring, and the surface of the rails finally dressed smooth, so that the passing of the car will be the same as on a continuous rail. In preparing the joint better results as to smoothness are obtained by inserting a thin shim between the rails, than by placing the rails too close to admit of such a shim. These cast-welded joints should be so formed as to present the least amount of interference with the wearing surface of the pavement.

In general, the wearing surface of the paving between the rails should not be of better material or smoother than the balance of the street, otherwise there will be an undue amount of vehicle travel on the street railway tracks and consequently more frequent accidents will occur. Attention should be paid at all times to drainage, and at street crossings where the established grade is level, the surface of the tracks on one side should be elevated several inches to prevent the retention of water pools. At all changes of grade the rails should be bent to form vertical curves, and these vertical curves should contain no joints, as otherwise it would be almost impracticable to secure uniformity in curvature without resort to shop work.

ELEVATION, SECTION AND PLAN, DOUBLE TRACK CONSTRUCTION, KANSAS CITY

There is no economy in trying to construct a railway hastily, as in so doing the work is often slighted in some particulars, and this involves future expense.

The special work, turnouts, crossings and cross-overs should be of cast steel construction, except at steam railway crossings, where the best built-up work located on foundations should be used. The tongue of turn-out switches should be placed on the high or super-elevated rail of the curves, otherwise the guard rail of the mate should extend the full length of casting on which the tongue is located. All curves with a radius of less than 300 ft. should be provided with a guard rail, and curves of less than 50-ft. radius should be double guarded.

A very important matter in the construction of street railways is that of drawing up the specifications and final contracts. Great care should be taken that these cover all the material and labor necessary to complete the entire line. Neglect of this precaution often entails serious trouble and is expensive.

When a line is constructed as herein provided its maintenance is a question almost entirely of car equipment, involving the wheel base, double or single trucks, diameter of wheels, properly applied springs and weight of cars. The longer the wheel base the less durable the curve. Single trucks will batter out frogs, switches and joints more rapidly than double trucks.

The Care of Car Equipment

BY J. H. VANDER VEER

In giving the writer's views as to the proper care of car equipments he expects them to be thoroughly criticised, though it should be borne in mind that different conditions obtain in different cities.

On the railway with which the writer was first connected, all the cars owned were kept in service except from 8 P. M. to 6 A. M., during which time all inspections were made and all possible overhauling done. If a car broke down during the day every one possible, including the motorman and conductor, was put to work on it. As the motormen in those days carried kits of tools with them and inspected the motors at the end of each round trip, they were very helpful when it came to overhauling. That period, however, has passed away, together with the double reduction motor.

In the maintenance of motor equipments to-day, where almost continuous service is demanded and high mileage made, only those equipments which are fitted with both oil and grease boxes will safely run over forty days without a thorough overhauling. This overhauling, on a large road, must be done at a number of different points, at each of which it is advisable to have extra trucks mounted with motors, all in first-class order, ready to run under a car body whose equipment needs inspection. To properly lift the body from the trucks four duplex chain hoists, or air jacks, conveniently located, together with two cross timbers and four stirrup irons, form as good a combination as can be found, and will do the work with the least possible injury to the car body. When the car body is lifted, the truck to be overhauled is run out and the good truck substituted, the car lowered, connected up and turned over to the operating department. The operation takes about one hour, and for that length of time only is the use of the car body lost. A suitable crane, properly located and equipped with a carriage and a second duplex or air hoist, will also be found of great convenience. Such a crane can be readily made in any blacksmith shop and for the arm a piece of old rail can be used. When the motor is opened, the armature should be lifted out and placed on a suitable rack, where the commutator can be cleaned and armature tested for insulation. The fields should also be tested for drop in voltage, and where there is a drop those fields and armatures should be used in motors by themselves, keeping new and rewound fields and armatures in motors by themselves. This prolongs the life of the equipment and reduces the number of crippled cars taken off the road. The motor shell should be thoroughly cleaned out, either by compressed air or by washing with kerosene. The grease in the grease boxes should be taken out and put in the gear case and the grease boxes thoroughly washed out with kerosene. The brush holders should also be taken out and thoroughly inspected and cleaned.

The writer has found that the work described cannot be properly done in the pit, with the car body on the truck and the bottom half of motor dropped. He recommends, therefore, the removal of the car body, as described, a step which also saves tying up a complete equipment while the motor inspection is being done.

In general, a car, starting in perfect order, will safely run five days before requiring inspection.

The force required to inspect from twenty to twenty-five cars per day would be about as follows: One man can be responsible for the proper inspection of all trolleys, including the taking out and replacing of any defective poles, wheels or springs, and the straightening of all bent poles. Another man should be responsible for the proper inspection of all circuits, together with hood switches, fuse boxes and lightning arresters. Another should give his whole attention to controllers. A fourth, with an assistant, should be able to keep all brakes in good shape and replace all worn out shoes. This force should keep the truck and motor equipment in good shape, if the night men take equally as good care. The writer recommends doing as little work as possible at night. At a car house operating say one hundred cars, three men should be able to grease motors, inspect brushes and make any small trolley repairs. Car cleaning should come directly under the operating department. The night car cleaning should be limited to sweeping out, cleaning windows and dusting cars, and all washing should be done in the day time while the car swings or is on the stand, if the car house is at one end of the line. If the cars are

of the closed type, the seat risers, drop sash and the space under the seat should be cleaned once a week, as the traveling public has a tendency to drop newspapers, apple cores, etc., behind the seat back, not to mention the bits of lunch the motormen and conductors drop there if their runs compel them to eat on the car. The best way to avoid this and to also save the annoyance of a rattling sash, is to make the sash stationary and cover over the space between the top of the seat back and sash rail. This, of course, does away with blinds and compels the use of curtains. The cost of maintenance is less with curtains, however, than with blinds.

A car house from which one hundred cars are operated should have, among its employees, a good carpenter to make small running repairs and to take care of bell cords and register ringing devices. Any car that has been in a collision and damaged so badly that it cannot be repaired in one day should be sent to the general repair shop. All cars should be taken to the general repair shop once a year, the body put in thorough repair and the car varnished or burnt off and painted anew, as the case may demand. While the car is in the carpenter's hands the wiring should be gone over carefully and put in shape. If the car goes to the shop with its regular truck and motors, the former should be run out and gone over thoroughly. In case it is a built up truck, all rivets and bolts should be carefully inspected and renewed where necessary. In the case of a solid side frame truck, it should be carefully squared to see that it has not sprung. The brake rigging should be taken apart at this time and if it is a truck with brake beams working in slides the beams should have what are termed "Dutchmen" jumped into the ends to bring the wearing parts back to their original thickness, as the beams will probably be found to have worn wedge shaped. If the brake beams are hung by links, these should be renewed if they show signs of wear. At this repair shop should be concentrated all classes of repair work, not only repairs to bodies and trucks but all electrical repairs. The writer believes it pays all railway companies to make their own repairs to electrical apparatus, including the making of armature coils and renewing of commutators.

In connection with the latter the writer has found that hard drawn copper makes the best commutator. This is bought in lengths and the bars sawed off with an ordinary metal saw. It will be found that the same bar will often do for several types of commutators. In making commutators it is well to increase the diameter over those turned out by the factories as much as can safely be placed between the brush holders. Drop forged bars can also be purchased for any width of commutators desired.

As regards controllers, hood switches, etc., most roads will find it cheaper to buy the ordinary repair parts and then assemble them, themselves.

In conclusion, the writer has found it is advisable to make car body repairs, rewind armatures, make commutators, armature coils, field spools, etc., by piece work. If good inspection is provided and the prices honestly watched, both the company and its employees are gainers by this method. The writer has in mind a case in point. A shop was operated by day work and the regular carpenters' wages were $2.25 per day of ten hours. Cars that were being remodeled were costing $120. This was changed to piece work and the same results secured by paying four men $110 per car. It was found that the men could do the work easily for this and make about $6 over their regular wages. They soon became so expert at this line of work that the price was gradually cut to $80 per car. Cars are being turned out at this price now, and the men are averaging $2.50 per day. Close inspection, however, is a necessity.

Car Mileage

BY H. C. MACKAY

One of the greatest problems affecting the street railway interests is an equitable and standard unit for comparing results, and the subject assigned will be treated in its general relation to accounting as such.

Car mileage has been adopted by practically every road in the country as the unit of comparison, but a study of the methods used in computing the mileage made by the different systems will convince anyone that under the present conditions it is misleading and unreliable. It makes but little difference what is used as a basis, as long as its purpose is simply to show if the earnings or expenses are proportionately above or below that of a similar period; but to make a comparison with another system, whose speed, length of day operated, size of cars, etc., are different, or where the physical conditions are dissimilar, it is absolutely necessary that the unit be identical.

It is not practical to make general comparisons of any given expense item as to the amount in dollars and cents, for the reason that there are so many factors to be considered which have a direct bearing on the cost; hence, it is necessary to reduce same to a basis alike to all systems. When this has been accomplished, the result of the operations of the various systems will establish an average for each division or item of expense, which will be an accurate guide to the manager; an indicator showing all expense items in which reductions should be made. Here is where the greatest value in a standard unit lies; the cause of an abnormal expense is at once detected and the energies otherwise wasted in an endeavor to locate the trouble can be applied in the correction of it.

The principal objection to "car mileage" is the variation in speed. Between city and suburban lines there is a difference of from 8 miles to 30 miles, or even more, per hour. The increase in speed does not materially affect the cost of operation. The liability of accidents due to increased speed are more than offset by the difference in density of population of district traversed, while the principal items of expense, such as "wages of conductors, motormen, car-house employees, etc.," are the same in either case; hence, the suburban or interurban line would show from two to four times the number of miles run, at only a slightly increased cost as compared with a city system. The question may be asked, why the interurban line should not be entitled to the credit of operating at a less cost (as the object of a standard unit is not to make expenses uniform, but to show the actual conditions). I will answer the above by saying that while the cost "per car mile" would be less, on the basis of passengers carried, it would be more, by reason of the longer haul, thus indicating that its expenses are not proportionately less except upon a basis favorable to itself.

Another disturbing element is the "trailer." Where trailers are used regularly and to any considerable extent, they are considered as a separate car mileage, being computed for both motor and trailer in nearly every case. Theoretically, a system whose equipment is exactly adapted to its needs, would assign to runs cars of just sufficient capacity; the trailers being abandoned, and in the place of, say a 22-ft. motor and 18-ft. trailer, a 40-ft. motor car would be run, thus eliminating the expense of one conductor, as well as the extra maintenance charges.

New cars are rarely purchased for use as trailers on electric systems. Those in use are either relics of horse-car days or an indication of an extraordinary growth of the city, and consequently of the system; an indication that the capacity of the car is not equal to its requirements while it is still in good condition and too valuable to be consigned to the scrap pile or even to be sold at forced sale, so its motors are placed under a longer car body and it is transformed into a trailer, to be brought out and used as an attachment or extension wherever the motor car's capacity is liable to be overtaxed.

Surely, no one will contend that it is cheaper to operate a motor and trailer, whose combined length is 40 ft., than a motor car of the same length. If it were true, the same rule must apply to a 24-ft. car, and we would be substituting a 12-ft. motor and 12-ft. trailer in its stead, yet the method of computing both motor and trailer mileage attempts to show just this result. To better illustrate, we will take for example two roads, one using 40-ft. motor cars, the other a motor and trailer whose combined length is 40 ft. They are operated at the same speed, headway, etc., yet the first shows a cost of, say 12 cents per car mile; the other, by reason of the double mileage, a little more than one-half of 12 cents, though with the additional expense of an extra conductor. My contention is, that a road using trailers is naturally handicapped and should not be expected to produce as good results as one whose equipment is nearer adapted to its needs, and that the trailer is but an extension of the motor car and the extra expense of running it should show as the result of unfavorable conditions.

To secure data, the writer sent to most of the railways of the United States and Canada a circular letter, requesting answers to the following questions, viz.:

1. Is your mileage computed from conductor's trip reports? If not, how? Answers were received from 103 roads, and were as follows:

Conductor's or motormen's reports	73
Foremen, dispatcher or switchmen's reports	15
Time tables	4
Unanswered	11
	103

From the above we see that over 70 per cent of the total number and still greater per cent of the answered reports arrive at mileage from the trainmen's reports. Some few companies have adopted a system whereby the conductor reports his route run by numbered points, each switch, cross-over, etc., being given a

number, permitting the accounting department to accurately trace the car. It requires, however, a careful examination of each trip sheet, which, to a large system, means the expenditure of considerable time. I suggest that the trainmen be required to report only the exceptions to their regular trips, either lost trips or extras made, thus, instead of going over all the trips made during the day, only the deviations from the regular schedule would be examined and computed. This result may then be added to or subtracted from the regular schedule. The method adopted would depend upon a conclusion as to the following question:

2. Do you keep record of mileage made by each car? Answers:

Affirmative	51
Negative	46
Unanswered	6
	103

Of the above fifty-one roads that keep such records, twenty-six are in cities of less than 50,000; ten are in cities of 50,000 to 100,000, and fifteen are in large cities.

Neither of above questions has any bearing on "car mileage" as a unit, except so far as accuracy is concerned. A great amount of data is usually prepared by the accounting department to which reference is seldom made. Mileage by cars is valuable and necessary to determine the life of wheels, gears, pinions, etc., but these tests are of a semi-occasional nature, and special records can be kept in such cases at a less expenditure of time and money.

3. What method have you of verifying above figures?

Answers:

None but care in computing	45
Time tables	28
Dispatcher's reports	8
Pay rolls	4
Foremen's reports	4
Motormen's reports	3
Trip receipt returns	1
Unanswered	10
	103

It would seem that the simplest method of verifying the results would be by a report from the foremen showing deviations from the regular schedule, and this result checked by trainmen's reports.

4. Do you include dead mileage, i. e., from station to where car strikes regular route?

Answers:

Negative	50
Affirmative	36
Have none	11
Unanswered	6
	103

The reason assigned why dead mileage should not be included is that the car is not earning revenue, and that it would be unjust to decrease its earnings per car mile. Nevertheless, the mileage had to be run before it could earn revenue; the expenses were the same as when on regular service, and I consider it legitimate mileage. Thus, the systems whose stations are advantageously situated would receive whatever benefit there was due to that fact.

5. Do you include full trailer mileage? If not, what proportion, and give reasons why full mileage is not used?

Answers:

Trailers not used	46
Affirmative (of which number only 50 per cent use trailers regularly)	37
Negative	11
Unanswered	8
One-half	1
	103

The percentage of roads using trailers regularly, as shown above, is only about 20. As stated before, the trailers should not be computed for general use.

6. Is any allowance made for partial trips lost?

Answers:

Affirmative	57
Negative	37
Unanswered	9
	103

This question is covered under No. 4. Allowance should be made for partial trips lost, or, in other words, mileage used should be the actual mileage made by motor cars.

7. What is your average motor mileage per day? Trailer?

8. What clerical help is required for mileage work and approximate cost per month for same?

9. How long does it take to ascertain the total mileage for the day?

The object of the preceeding questions was to determine the relative cost and adaptability of method used, but, owing to the different construction placed upon question No. 7 (answers covering average motor miles per day per motor and total miles per day) no conclusion can be drawn except that the speed varies, so that the average motor miles per day per motor ranges from 65 miles to 300 miles.

10. Do you use "cars operated per day" as a basis for comparison of earnings? If so, what constitutes your car day?

Answers:

Affirmative	44
Car day of 20 hours	1
" 19 hours	1
" 18 hours	31
" 17½ hours	1
" 17 hours	3
" 16 hours	1
" 15 hours	4
" 115 miles	1
" 80 miles	1
	44
Negative	48
Unanswered	11
	103

Car days, especially in the larger cities, are gradually lengthening, and will no doubt reach the maximum of twenty-four hours.

The adoption of the "passenger mile" (being the passenger trip distances divided by the number of passengers carried) is precluded, owing to the impracticability of obtaining the length of the separate passenger trips.

This applies to the "ton mile" as well, if the element of "passenger weight" is taken into consideration. If the "ton mileage" is based upon the dead load hauled, I do not consider it complete. In fact, the showing made on the basis of "ton mile" would have a tendency to mislead the management. For example: One system operating "20-ton motor cars," with a corresponding large ton mileage, would show a small cost per ton mile. Another system, operating "10-ton motor cars," would show nearly double the cost per ton mile, when as a matter of fact the lighter car may be the more economical; but, with the mileage computed carefully, all dead miles included, and the elimination of the trailer, we have a unit which will be uniform and applicable to all electric systems as soon as the question of speed is adjusted; hence, we have but to divide the above figures by the average rate of speed and this result, verified by the motormen's time, will be a standard unit. This is equivalent to a "motor-car hour."

To illustrate the method of ascertaining and verifying the "motor-car hours," at the same time showing the effect that speed has upon car mileage as a unit, I submit the following exhibit:

TRAFFIC SHEET

	A. B. Ry. Co. Operating City Line	C. D. Ry. Co. Operating Interurban Line
Number of cars operated	3	3
Speed per hour (miles)	8	24
Length of trip	24	24
Number of trips per day (regular)	18	54
Extra trips made	2	6
Trips lost	½, 1½, 19½,	1½, 4½, 58½
Miles per day	19½, x 24, 468,	58½ x 24, 1404
Motor car hours	468 ÷ 8, 58½,	1,404 ÷ 24, 58½

PAY ROLLS

Motormen's Time		
Regular trips	18	54
Extra trips	1½	4½
Total trips	19½	58½
Motor car hours	19½ x 3, 58½,	58½ x 1, 58½
Assuming the cost of operating above cars at $60 per day, the cost per car mile would be	$ .12.82	$ .04.27
The cost per hour would be	1.02.56	1.02.56

From the foregoing exhibit we see that the time table of the city system shows eighteen regular trips per day. From the conductors' and foremen's reports we find two additional trips were

made and a half trip lost, a net addition of 1½ trips, or a total of 19½ trips, amounting to 468 miles. This amount, divided by the speed, equals 58½ motor-car hours. This figure is verified by the pay roll. Time allowed:

Eighteen trips, at three hours (regular)	54 hours
One and one-half trips, at three hours (extra)	4½ hours
Total	58½ hours

For the purpose of comparison, the interurban line is based upon the same conditions, excepting speed, which is increased from 8 miles to 24 miles, thus increasing the mileage without changing the car hours.

It will thus be seen that on exactly the same cost the city system would show 12.82 cents "per car mile," as compared with 4.27 cents, while on a basis of "motor car hours" the cost is the same.

It has been contended that the unit for earnings should be the "motor car hour," and that operating expenses should be based upon the percentage of earnings.

The car hour certainly applies to earnings just as well as it does to expenses, but I do not think that a percentage of earnings is the correct basis. For a standard unit it is too fluctuating. If a road's equipment was always taxed to the limit, its earnings and expenses might be held at a fairly uniform basis, but these conditions would never exist for any length of time, and could not become general. Any large convention or carnival would swell the earnings abnormally, and while the expenses would increase at the same time, they should not in the same ratio; hence a comparison of the month's result under such circumstances with another system under normal conditions would be unfair.

Again, the geographical location would disturb fair comparisons, as the time of the year when expenses would be proportionately low in a Northern city would undoubtedly be just the reverse in New Orleans or other similarly situated places.

It has also been suggested that the sub-divisions of "general expenses" are not consistently covered by the "motor car hours," and that such items as "advertising and attractions" and "insurance" are not affected by the number of car hours run. So far as such accounts as these are concerned, the same may be said of any basis. Good management will always keep its car hours as near the point where profit and loss separate as is possible, whether on a large or small system, and while such accounts may not be affected by the car hours, nevertheless, the said hours being the index as to the management, the amount of such expenditures is proportionately and correctly shown.

Before concluding I wish to briefly refer to an article on the cost of electric power for street railways at switchboard, by R. W. Conant, read at the last convention of the American Street Railway Association; quoting therefrom: "The car-mile basis is not a fixed standard. A car, up hill, takes a great deal of power, while a car down hill should take none, and may be made a source of power." This is undoubtedly correct, as all grades and loads affect speed, and without this adjusted, mileage is not a fixed standard, but with the speed taken into consideration it would be practically the same as on a road without grades.

Report of the Department of Blanks and Forms

BY W. B. BROCKWAY

When the call was issued for the meeting which organized this association, it also included the suggestion that the companies represented at that meeting should bring samples of their blanks and forms in order that helpful and suggestive comparisons could be made. The idea was so well received that a long table was necessary to display the collection. As a means of exhibition the blanks of each road were placed in a pile by themselves, but the contents could only be ascertained by a detailed search of the pile. The popularity of the exhibit was attested by the constant attention it received and by the packages of exchanged blanks most of the members carried home with them.

At the first annual meeting held in Niagara Falls, Oct. 1897, the plan was again tried, but for various reasons it was not so successful as the previous experience at Cleveland. However, a committee was appointed to arrange the blanks presented, and their work was as well done as the blanks and room would permit.

In view of the accepted importance of the idea, it was decided for the convention at Boston, in 1898, that a special effort should be made to have the exhibit of the size and bear the results it deserved. Therefore, a committee of arrangements was appointed from among the gentlemen contiguous to Boston, who issued a special circular and those attending that convention are familiar with the thoroughness and popularity of their work.

It was really the object lesson given by the orderly display of the blanks of the Montreal Street Railway, at Niagara Falls, in 1897, and the classified collection exhibited by the committee at Boston in 1898, which called forth the resolutions establishing the Department of Blanks and Forms and making it a permanent part and feature of the advantages of membership in the association.

The blanks as they are exhibited this year are mounted in thirteen large books 20 ins. x 30 ins. and one 30 ins. x 30 ins. These books are bound in canvas and are made from special 120-lb. manila paper, which will assure the wearing qualities needed for exhibition year after year. For the convenience and safety in transporting these many heavy books, there has been provided an oaken box with a shelf for each book, securely locked. And that there may be no reason for heavy handling, end over end, it is mounted on heavy castors that it may be readily moved.

In the whole physical make-up of the department, care has been taken to make the wearing quality as good and permanent as possible. And the assistance authorized at Boston and engaged by the secretary has been of high order rather than cheap, feeling confident that the result would be well worth the care and expense. The exhibition, it is hoped, will bear out the soundness of that reasoning.

As a foundation for the blanks preserved there was taken those exhibited at Boston, which, it will be remembered, amounted to several thousand; to this already fine collection there have been added the private collection of the secretary and the complete sets of very many other companies, so that at the present time there are complete or semi-complete sets of upward of eighty companies, many of which are the representative companies of the continent.

The secretary takes this opportunity to thank most sincerely the companies contributing for their cordiality and promptness in granting original and the many special requests made for additional copies of blanks, that duplicate and triplicate filing might be made where the construction of the blank demanded it. This co-operation has materially lessened the burden of preparation.

Many methods of classifying were considered, but there were but three which seemed feasible for so large a collection of diversified blanks as this one, viz.:

1. *By companies*, whereby the blanks of each company would be placed together in rotation.
2. *According to the standard classification*, in which those blanks relating to each account of that classification are filed under the different headings.
3. *Logically*, by which is meant the arrangement into classes all blanks of all companies intended for a similar use.

The last plan was adopted for the reasons that if the arrangement by companies had been followed it would still have been necessary to have followed some general classification of each company's blanks. But in the practical use of such a filing, a company satisfied with its entire form list, except this or that blank, would be unable to obtain a comparison without searching through every book in the collection, and even then to compare any two blanks on file, possession would have to be had of two or more books, which, according to the law of average, would be perpetually in use by some one else, which objection would make the annual exhibition a difficult one to make use of.

And in considering the arrangement according to the standard classification of accounts it was found that there were many blanks which applied to more than half the accounts which, to make the filing complete for each account would frequently require the possession of as many as forty copies of a blank that the face and back could be shown. This is illustrated in the blanks relating to labor, it being obvious that there are few of the thirty-eight accounts in which labor does not form a prominent part. This difficulty seemed so insurmountable that this plan could not be followed.

In view of the difficulties and objections found in other plans which, to make the filing understandable, had to be omitted in the plan adopted, it seemed to be better to make certain classes to contain blanks of all companies. This will permit the closest comparisons in each class and will at the same time include in one book all blanks of all companies which will in any way relate to that class. It is true this plan has broken up the continuity of the blanks in use by the individual company, but we have substituted a continuity in which all the companies join, for there is a certain channel through which the business of a company must run in its performance and the various changes in the direction of that channel have been followed as closely as was possible. For instance, in the books containing income it will be noticed that book A, starts with the first record of income, viz.: conductors' reports; these are followed at once by the report envelopes, the receipts of the receivers, the reports and records of the counting and verifying clerks, etc. Thus there has been a natural sequence kept in mind, but it is one in which all the railroads join for the benefits of a prompt and efficient comparison. It is sincerely hoped that the

reasoning by which this plan of filing has been adopted is sound for the amount of study and time involved is considerable.

The three fundamental divisions into which the collection has been separated are:

1. Income.
2. Expenses.
3. Records and reports.

These are separated further into classes which can be best shown by the following description of the contents of each book.

Book No. 1. Income A, consisting solely of those books relating to the handling, reporting, verifying and depositing the actual cash income, and the daily, weekly and monthly reports of earnings only.

Book No. 2. Income B, contains tickets and transfers, their records of received, used and on hand, and physical records of registers.

Book No. 3. Labor A, includes the application, investigation, hiring, disciplining and discharging of employees.

Book No. 4. Labor B, covers all the various steps of paying the employees, from the time reports to the comparison of pay rolls.

Book No. 5. Materials, is for those blanks for material only, from the request for, through the purchasing, receipt and issuance to inventory.

Book No. 6. Maintenance, consists of the reporting of work done outside of and in the shops. The records of wheels and axles, and other blanks not strictly labor or material, but rather the result of their combination.

Book No. 7. Power-house, this book contains everything relating to the power-house—labor, maintenance, operation and efficiency. All blanks of each company are filed in this book by themselves.

Book No. 8. Transportation A, covers the actual operation of the cars from time tables through the various steps of dispatching and running.

Book No. 9. Transportation B, is the miscellaneous needs and results of the operation of cars, as instruction to trainmen, secret inspection, lost and found articles, cleaning snow and ice, car mileage, stables, benefit association, etc.

Book No. 10. Injuries and damages, takes the accident from the original report of to the settlement and records, and summaries.

Book No. 11. Vouchers, etc., is for the vouchers, bills, journal entries and various office stationery.

Book No. 12, contains monthly and annual reports and comparative statements of earnings and expenses.

Book No. 13. Records, includes voucher, accounts receivable, check, cash and other general records.

Book No. 14. Electric lighting, consists of all blanks relating to electric lighting as a business of itself.

To make the books useful for ready reference a system of cross indexing has been provided for each book, by the use of which a company intent upon only the conductor's reports of the X. Y. & Z. Railway can readily turn to it without searching for it until found. These indexes will be found inside the first cover of each book and will explain themselves, and as a means of assistance to the casual looker-on, each page has been labeled at the top to show what form that page contains, so that in the rush of convention hours " he who runs may read." Small figures in green will also be found in some corner of each blank to show the date of the original filing. This is done that an intelligent idea may be formed of the changes from year to year.

In many instances it has been important to make a duplicate and sometimes a triplicate filing. This is caused by the combining in one blank the information covered by two or more of the divisions into which the collection is separated. It was thought better to file as many times as necessary so that the specialist intent upon but one form will still find the collection as complete as possible within the limits of the blanks filed.

In all cases where a blank contains a form upon both sides, each side has been shown and an explanatory stamp has been impressed upon it, showing that it is the "front of" or the "back of" the form to which a hand points. This will save confusion. It is expected that errors of omission and commission will be found both in the classes selected and in filing, and it will be of great assistance if a memorandum be made of each error and handed to the secretary that attention may be given to the correction.

As to the practical working of the department there is to report that the books comprising the official file and annual exhibit are intended to remain in the office of the secretary for continual additions, and they will only be moved to make their annual appearances at the succeeding conventions. For the use of members there has been provided a reserve set, unmounted, which are at all times subject to the request of those entitled thereto. A letter of request is an application and the secretary makes a selection from this reserve set and forwards it to the applicant. Accompanying them is sent a blank giving such information needed to make clear the length of time they may be kept and the cost (which is always nominal) to the applicant.

This reserve set is treated on a library basis and selections should be returned upon the date allowed (usually thirty days), as it sometimes happens there are other roads awaiting their return to get the set which is in use somewhere else. It will be of interest to say that this occurs oftener with those blanks relating to materials and supplies than to any other.

In a circular, No. 9, issued from the secretary's office, attention was called to the many requests for sample blanks which every company received. It may be well to repeat the suggestion made, that all such requests be referred to the secretary, who will gladly fill the request, if the company making it is a member of the association, or will courteously decline if not. By this action considerable trouble and expense is saved the individual company, and new members will be gained to the association.

While I do not feel qualified to make any extended criticism of the size, shape or other characteristics of the blanks on file, there are found in working over and studying so large a mass of blanks and forms, certain little kinks or tricks of practice which have become almost a habit and, while they are harmless and unnoticeable while by themselves in use on the roads where they originate, yet when included in a collection the size of this the comparison is more or less marked, and I cannot refrain from making a brief reference to some of them.

The most prominent of these is the omission of the name of the road. It is not a bad guess I am sure, to say that of the thousands of blanks filed, 30 per cent are without any mark of personality. Very many and devious were the schemes tried to locate blanks, of which another copy was necessary, for duplicate filing. For instance, one very important blank was recognized only when the water mark in the paper was compared with other blanks till one was found of the same kind, and from this blank we were enabled to find the issuing company. In another case an explanatory note was written on the face of a blank, of which we again needed additional copies, and in this instance no less than twelve different blanks were found with an explanation in the same handwriting, but not one had an identifying mark. The company was only found by comparing the handwriting with the correspondence on file in the secretary's office. It was absolutely necessary to the value of the collection that these two cited should be duplicated, hence the efforts made to locate them.

If there can be any second choice in the shortcomings now being referred to, it is perhaps best covered by the term "ambiguous." A number of these are of undoubted importance to the companies making use of them, yet in the hands of one unfamiliar with the ins and outs of the particular roads by which they are used, they become almost meaningless and many were the inquiries sent out by the secretary where a few words printed at the head of the blank would have made the use clear.

In the next thought the other extreme is brought out, and I can think of no better term with which to describe it than "persistent information," meaning thereby the repetition of information in two or three blanks. The persistency of some forms reminds one forcibly of the annual report required of the steam railroads by the Interstate Commerce Commission, wherein questions are asked in so many ways as to be almost bewildering at times. This class of blanks made their filing very difficult, requiring many times a duplicate or triplicate filing to properly care for the various information, most of which was contained in other blanks already on file.

While not the most important, perhaps the most prominent feature of the whole department is the tremendous lack of uniformity in the shapes and sizes of blanks intended for the same service by different roads. One of the largest city companies in the United States has a report measuring 2½ ins. x 4 ins., while another road of about the same size requires a sheet 8 ins. x 12 ins. for but little more information. In another case one company uses two pages (meaning cross-pages) for a book of record, where another has precisely the same columns and headings and needs but one page, and that smaller, the difference being in the space allowed for the columns. The larger one has a date column of 3 ins. in width, and the number of reports from which the record is made has room enough to run up into the millions with still room to spare. These are extreme cases, but the principle is unchanged.

Careless press work and ridiculous selection of type make in some instances a jarring effect upon the other extreme, often found in that of beautiful and artistic work on the part of the printer, because he knows nothing but that kind of work will be accepted, and is governed accordingly. In this connection there is another practice, about which much pro and con can be said. I refer to the paper used. There is a vast difference in the cost of "cheap yellow" and ledger linen, but you will find forms intended for similar uses thus dissimilarly made. There is an average where ser-

viceability and economy can and do meet, but it requires an exacting—not petty—management of this branch of the expenses of a railway property.

Further suggestions can properly be made to the desirability and usefulness of form numbers, whether to make them continuous or to have a set for each department as applied to a small road or a large one. And again to the multiplicity of blanks burdening a small road as compared to a large one with not enough to properly attend to its volume of business, both external and internal. Other suggestions readily occur to one while examining the collection, but I will call your attention to but one other to which I have applied the title "Confusion," or perhaps a better one would be "Lack of Care in Arranging." By this I mean the jumbling together of all kinds of information upon one large sheet, and further, the placing on both sides of that the information intended for the busy financial or operating man who depends upon your statistics for various information, and has literally to search for what he wants. This, it seems to me, is caused by a desire to utilize every inch of space of a larger sheet, rather than to cut it into smaller ones with information of a similar nature grouped together.

On the other hand, as compared with these few criticisms, there will be found very much to commend, admire and use in the mass of blanks brought together. There is in many an evidence of careful thought and artistic sense, which shows itself in the composition of the blanks of this or that road. There is as much need of genius in the building of blanks and forms, as much a demand for brains and foresight in the logical arrangement of columns and statistics upon paper, as there is in the management of an office, for on one side is "Stationery and Printing and Office Expenses," and on the other "Surplus from Operation."

Fuel Economy of Railroad Engines*

BY PROFESSOR R. C. CARPENTER

In the following papers are given the results of thirty-five tests of electric railroad power stations, which have been made during the past eight years under my supervision, by especially trained students in advanced work in Cornell University.

The tests which are cited were made under the ordinary conditions of operation peculiar to the system referred to. In every case the results were doubtless affected by the machinery employed, the method of operating the station and by the varying and continually changing load produced by irregularities in loading and moving of cars.

The tests show the fuel consumption of several classes of engines, operating under the usual condition of power-house work. There is shown a variation in the fuel economy by engines of the same class, operating in different stations, which in some instances is of considerable amount. This is probably to be expected, for it is well known that the economy is affected to a great extent by variation in load, since an engine fully loaded is in general much more economical than one partly loaded; no duty throws on an engine a more variable load than street railway work. A certain amount of the variation in coal per horse power, as shown by the tests, may be accounted for by individual differences due to poor or good firing; this may, and often does, make 20 per cent or more difference in fuel economy, and this condition affects the uniformity of the results in about the same proportion. The effect of employing different classes of engines is also well marked. The fuel consumption of different classes of engines is doubtless the most interesting and practical part of the investigation. If we can learn from the tests the probable fuel consumption of each class of engine, we can draw conclusions as to the saving which might be produced by change of power, and we can also predict with certainty the fuel charges for different classes of stations.

TESTS OF THE SIMPLE NON-CONDENSING ENGINE. SLIDE VALVE AUTOMATIC

The summary of the tests of the simple non-condensing engine shows on the whole an economy of steam and coal nearly equal to that usually attained with engines of this class in any work. The most probable values indicate an average consumption of 34.3 lbs. of steam and 4.63 lbs. of actual coal per i.h.p. per hour.

In tests made by the writer with an engne of this class operating with a steady load, the best results at the normal load corresponding to about one-quarter cut-off, was slightly over 27 lbs. of steam per i.h.p. per hour, the steam consumption was greater either with a lighter or heavier load. As an illustration, the diagram on page 802 exhibits the results of a series of tests made on an automatic slide valve engine running non-condensing. Each test was continued sufficiently long at a given load to obtain the water consumption for that condition. The results are shown in the accompanying diagram, by employing horizontal distances to represent horse power, and vertical distances to represent steam used per horse power per hour. The scale on the left corresponds to the curves showing steam; that on the right, to curve showing total steam per hour.

The curves show graphically how the steam used changes with change in load. When the load is light the steam per horse power per hour is very great; when the load is normal, the steam consumption is lowest; when very high, the steam consumption per i.h.p. is increased. The total steam per hour increases faster than increase of load. The curve indicating steam per i.h.p. per hour shows slightly over 27 lbs. at 120 h.p.; nearly 30 lbs. at 150 h.p., 44 lbs. at 60 h.p., and 64.3 lbs. at 40 h.p.

Thus it is seen that a comparison of the results of the test of the automatic simple non-condensing engines in actual power-house work with those obtained under best conditions is in many respects favorable. The average results of all the tests show a steam consumption only about 25 per cent higher than obtained with this class of engine working under most favorable conditions.

This corresponds by the diagram to the results obtained with the engine tested at about 80 h.p., or at two-thirds its rated capacity. The average load as compared with the capacity of the engines in the various power-house tests was 54.2 per cent, which would correspond by the diagram to a steam consumption of 41 lbs. per horse power.

The following shows in tabular form the results of the tests of simple engines in a power house:

TABLE I

SUMMARY OF TESTS OF SIMPLE NON-CONDENSING SLIDE VALVE ENGINES

No.	H.p. of Engine	Steam per i.h.p. Hour	Actual Coal per i.h.p. Hour	Mean Observed i.h.p.	Per Cent Observed h.p. to Capacity	Boiler Evaporation per lb. Combustible from and at 212°	Kind of Coal
6	200	34.8	4.47	110	55	11.50	Pea A
1	405	34.5	(a) 6.54	257	63.4	(a) 9.11	Culm, East Ohio
7	1,975	35.7	4.60	862	51	9.46	Bit. W. Pa.
11	300	37.3	4 49	90	44	12.20	Bit.
11	300	34 3	4.72	95	46.7	10 20	Bit. Ill.
24	1,000	31.8	(b) 5.38	717	71.7	(b) 9 15	Bit.
31(c)	270	41.5	(c) 5.50	126	47.5	(c) 10 60	Ant. Buck.
33	270	31.6	4.61	147	54.5	10.70	Ant. Pea
Average		35.1	5.07	....	54.2	10.24	
Average neglecting (c)		34.3	....	....	....	....	
Average neglecting (a b c)		....	4.63	....	....	....	

Remarks.—Engine in test (31) in bad condition. Probable average coal per i.h.p. hour, when using anthracite or eastern bituminous, 4.63 lbs.; anthracite culm. 6.54; western bituminous, 5.38. Coal per kw. output averages 50 per cent higher, or 6.94, 9.81 and 8.07 respectively. Probable error for any given case not over 10 per cent Steam pressure, 90 lbs. to 120 lbs.

TESTS OF NON-CONDENSING SIMPLE CORLISS ENGINE. (SEE TABLE II)

Three stations only were tested which were using non-condensing simple Corliss engines. These three stations show fairly uniform results both as to steam and coal consumption, and, as was the case with the simple slide valve engine, the results closely approximate the best results to be obtained with that class of engine. Thus, while this class of engines might produce a horse power under favorable conditions of loading for an expenditure of 23 lbs. to 25 lbs. of steam used, the tests show an average steam

TABLE II

SUMMARY OF RESULTS OF TESTS OF SIMPLE NON-CONDENSING CORLISS ENGINE

No.	H.p. of Engine	Steam per i.h.p. Hour	Coal per i.h.p. Hour	Mean Observed i.h.p.	Per Cent Observed h.p. to Capacity	Boiler Evaporation per lb. Combustible	Kind of Coal
17	300	30.1	3.09	139	46	11.45	Clearfield Bit.
19	150	26.9	3.5	90	60	9.73	Ant. Buck.
22	350	28	3.77	153	44.7	8.55	Ohio Bit.
Average		28.3	3.45	....	50.3	....	

* This paper was to have been presented at the meeting of the New York State Street Railway Association, September 12-13. It was omitted on account of the unavoidable absence of Prof. Carpenter, but has been made part of the proceedings.

consumption of 28.3 lbs. of steam per i.h.p. per hour, the average load being slightly over one-half of the rated capacity.

The coal per i.h.p. per hour averaged 3.45 lbs.; the evaporation per pound of combustible varied considerably, which was due in part to the variation in calorific value of the coal used. The summary of the results of the test is shown in Table II. on the preceding page.

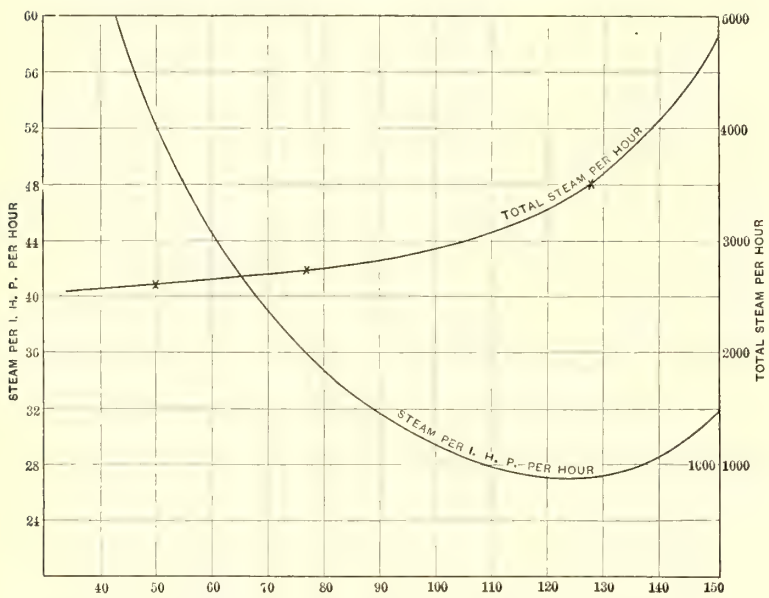
THE NON-CONDENSING COMPOUND ENGINE. (SEE TABLE III)

The data obtained relating to this class of engine is limited, and is probably insufficient to draw any general conclusion; four tests of power stations were made, in which such engines were used; these tests are numbered respectively 2, 4, 21 and 24.

The power-house tests No. 2 and No. 4 were made when both simple and compound engines were running; the results do not differ essentially from those obtained with simple engines and previously recorded.

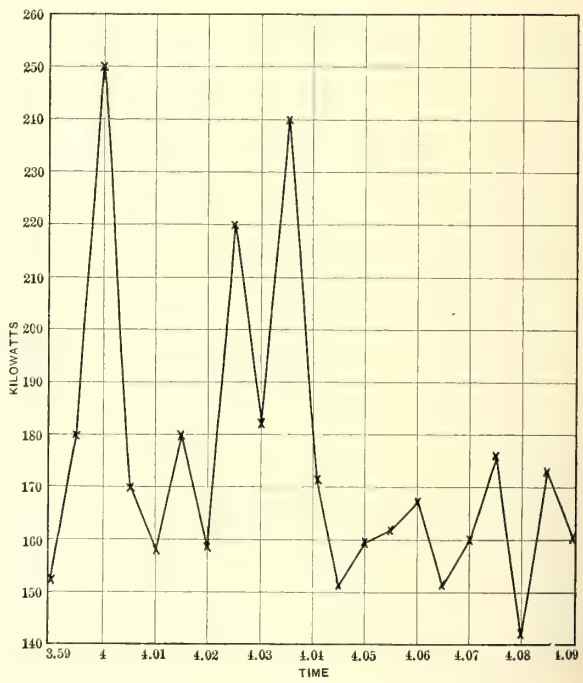
Tests No. 21 and No. 24 were made on non-condensing compound engines, working under fairly favorable conditions. Test No. 21 does not show better coal or steam consumption than many of the tests recorded for simple non-condensing engines; compared with No. 24 it shows a better coal record, due principally to the fact that in test No. 21 the coal used was from Western Pennsylvania, while that used in test No. 24 was from Illinois. The difference was due principally to the quality of fuel used.

It would hardly be safe to draw a general conclusion from the results in the table regarding the compound non-condensing, as compared with the simple non-condensing engine for railroad purposes, but such conclusion as could be deduced would be but slightly in favor of the compound non-condensing engine.



We have seen that the simple non-condensing engine performs its work in a railroad power-house under conditions of varying load with an average steam consumption only about 25 per cent higher than the best average record for its class of engines with a steady load. The compound non-condensing engine requires, on the other hand, however, nearly 40 per cent more steam than when working under best conditions with a steady load. From this

TABLE III



SUMMARY OF RESULTS OF TESTS OF COMPOUND NON-CONDENSING ENGINE

No.	H.p. of Engine	Steam per i.h.p. per Hour	Coal per i.h.p. Hour	Mean Observed i.h.p.	Per Cent Observed h.p. to Capacity	Boiler Evaporation Lbs.	Kind of Coal
2	1,000	30.5	4.22	603.5	60.3	9.03	Bit , 3 parts Ant.
4	1,250	36.8	4.33	674	53.8	9.92	Culm. 1 part. Bit. slack
21	400	34.20	4.17	203	51.	10.23	Bit. Penn.
24	1,200	30.37	4.93	754	62.7	9.01	Bit. Ill.
Aver. 21 and 24.		32.28	4.55	----	----	----	

Remarks.—Test No. 2 was made on three simple engines 150 h.p., one cross compound 250 h.p. and one triple 300 h p. Test No. 4 was made on three simple engines 250 h.p. each, and one compound of 500 h.p. Steam pressure, 100 to 125 lbs.

TEST OF SIMPLE NON-CONDENSING 14-IN. X 16-IN. ENGINE, 120 LBS. STEAM PRESSURE, 120 WATER H.P. 210 R.P.M.

CURVE SHOWING VARIATION IN LOAD OF RAILWAY ENGINES. HALF-MINUTE READINGS OF OUTPUT WITH FIVE CARS

Some additional information was obtained on this question by test (24) which was made on both simple and non-condensing compound engines, each kind being tested separately, and so as to give an opportunity of comparison. The test on three simple engines showed an ave age steam consumption of 31.8 lbs. of steam per i.h.p. per hour, and a fuel consumption of 5.38 lbs. of coal. The test on one compound non-condensing engine (24 in. x 48 in. x 48 in.) 1200 h.p. showed a steam consumption of 30.37 lbs. of steam and a fuel consumption of 4.93 lbs. of coal per i.h.p. per hour. The actual evaporation per pound of combustible from and at 212 degs. F. being in the test of compound 7.75 lbs., and in the test of the simple engines 7.83 lbs. of steam. Reducing the results for uniform evaporation, the two tests would indcate that the compound, as compared with the simple non-condensing, was 9.4 per cent more economical in use of coal, and about 5.5 per cent more economical in use of steam.

The compound non-condensing engine is much less economical, as shown by these tests, when employed in power-house work, where the load is variable, than when used for a steady load. Thus I have tested a compound non-condensing engine of this class working with a steady load and with about the same steam pressure as in the cases cited, and found a steam consumption under the best conditions of loading of 22 lbs. to 23 lbs. of steam per i.h.p. per hour, which is nearly 33 per cent better than shown by the same class of engines in power-house work.

limited data it would appear that the compound non-condensing engine is only slightly better than the simple non-condensing, and except under extreme conditions not sufficiently better to warrant its use.

No stations were tested using Corliss non-condensing compound engines, neither were any tested using simple condensing engines, and no engines of this class are known to the writer to be in use in railroad power stations.

THE COMPOUND CONDENSING SLIDE VALVE OR HIGH-SPEED AUTOMATIC ENGINE

The average results of the tests which were made in power stations using automatic engines of the slide valve type show a steam consumption of 23.96 lbs. and a coal consumption of 3.41 lbs. per i.h.p. per hour. If we reject the three highest values as given in tests 3 (a), 18 and 21, and the lowest result, as given in test 8 (b) we shall have for the average 22.7 lbs. of steam and 3.25 lbs. of coal per horse power per hour, which can doubtless be assumed to be most probably correct for this class of engine.

Most of the makers of engines of this class will guarantee them to produce a horse power per hour for a consumption of 18 lbs. of steam under favorable conditions of loading, and engines of this class have in several instances produced a horse power for less than 15 lbs. of steam. It will be noted that the best results with engines of this class was 16.7 lbs. of steam per i.h.p. per hour, and

2.4 lbs. coal per horse power, which was obtained with an engine of 400 h.p. of the four-valve type.

The effect of the variable load and other conditions due to railroad work is to affect the economy adversely by 30 per cent to 40 per cent, as compared with the best results with a steady load.

TABLE IV.

SUMMARY OF TESTS OF COMPOUND CONDENSING SLIDE VALVE OR HIGH SPEED AUTOMATIC ENGINE

No.	H p. of Engine	Steam per i.h.p. Hour	Coal per i.h.p. Hour	Mean Observed h.p.	Per Cent of Mean h.p. to Capacity	Boiler Evaporation, lbs.	Kind of Coal
3a	600	29.4	4.43	174	29	10.38	3 parts A; 1 pt. Bit.
3	600	23.2	3.50	190	32	9 93	1 part Bit.
8	400	20.2	3.14	154	38	8.29	Ohio Bit.
8b	400	16.7	2.40	180	45	7.75	Ohio Bit.
13	250	24.6	2.95	86	34.5	10.51	Bit. Penn.
16	350	22.7	3.41	164	47	9.50	Ant. Pea

Steam pressure, 100 lbs. to 130 lbs.

COMPOUND CONDENSING ENGINES, CORLISS, GREENE, MCINTOSH & SEYMOUR TYPES

The average results of the tests made on the compound condensing Corliss engines and other engines with similar valve gear, including McIntosh & Seymour and Greene, show a steam consumption of 18.8 lbs. and a coal consumption of 2.6 lbs. per i.h.p. per hour. Omitting test No. 10, for the reason that the coal was of a poor quality and the evaporation low, the average becomes 18.25 lbs. of steam and 2.36 lbs. of coal per i.h.p. per hour. The steam consumption of this class of engines working with a good load can safely be taken as 15 lbs. or less per i.h.p. per hour, in which case the actual results in power-house practice exceed the results when the load is steady by slightly over 20 per cent.

A study of these latter tests shows a higher evaporation per pound of coal than was obtained in power-houses using the cheaper grade of engines. This is probably to be explained by the fact that a better grade of engineers and firemen are employed to operate stations of this class, as compared with those using cheaper machinery, although it may possibly be an accidental variation due to the fact that only a limited number of stations were tested in each class.

The average evaporation from and at 212 degs. per pound of combustible was found to be as follows: for stations using the simple non-condensing engine, 10.26 lbs; for stations using the compound condensing slide valve engines, 9.82 lbs.; for stations using Corliss compound condensing engines, 10.54 lbs. of steam. It is not easy to explain why the evaporation is better from stations using simple engines than from those using compound engines of the same class, as the average grade of employees is rather better in the stations using compound than simple engines; probably the variation is an accidental one due to the limited number of stations of each class tested. The average range in the variation of results of the evaporation tests for the stations employing the three classes of engines does not exceed 7 per cent, and whether it can be accounted for or not it will not seriously affect the conclusions.

TABLE V

SUMMARY OF RESULTS OF TESTS OF COMPOUND CONDENSING, CORLISS, GREENE, MCINTOSH & SEYMOUR, AND SIMILAR VALVE MOTIONS

No.	H.p. of Engine	Steam per i.h.p. per Hour	Coal per i.h.p. Hour	Mean Observed h p.	Per Cent of Mean h.p. to Capacity	Boiler Evaporation, lbs.	Kind of Coal
10	825	22.7	4.05	482	58 2	8.29	½ Bit slack. ½ A Culm.

Evapo ation, 7.25 to 1 of coal.

Av'r'ge omitting No. 10		18.25	2.36	....	....	....	

Evaporation, 7.78 to 1 of coal.

SUMMARY OF RESULTS

A summary of the average results of these various tests is given in Table VI., in such manner that the various classes of engines may be readily compared. The best results with each class of engine when sufficiently well marked are also given.

A column giving the proportional value of the engine on the basis of coal consumption with a Corliss compound condensing engine placed at 100 is also given. A column giving the probable coal consumption per kw. hour is also appended.

TABLE VI

SUMMARY OF AVERAGE RESULTS

Class of Engines	Steam per i.h.p. Lbs.	Coal per i.h.p. Lbs.	Steam per i.h.p. Lbs. Best Load	Proportional Value of Engine	Probable Coal per kw., lbs.
(A) Non-condensing					
Slide valve simple, average	34 3	4.63	30	53.1	6.90
Best result	31.6	4 61	..	....	....
Corliss simple, average	28 3	3.45	25	64.5	5.65
Best result	26.9	3.01	..	....	....
Slide vaive, compound, average	30.37	4.17	22	60.2	6.12
(B) Condensing					
Slide valve, compound average	22.7	3.25	16	80.5	4.57
Best result	16 7	2 40	..	....	3.60
Corliss, compound average	18.2	2.36	15	100	3.64
Best result	14 5	1.80	..	....	2.70

RELATIVE ECONOMY OF VARIOUS TYPES OF ENGINES

Assuming that the results of the tests which have been cited give average and best results for engines of the different classes tested when working under the conditions of street railroad work, it is easy to compute the probable yearly cost of each class of engine, and by this means determine the relative value from a financial standpoint.

From the table last given it will be noted that the steam consumption per i.h.p. per hour varies from 34.3 lbs. to 14.5 lbs. A boiler horse power under the conditions of steam pressure supposed to exist would be about 30.4 lbs. of steam, although this amount would vary slightly, depending upon the temperature of feed water and upon the steam pressure. This computation would show that 1.13 boiler horse power would be required in case a simple slide valve non-condensing engine were used, while 0.6 of a boiler horse power only would be required for furnishing steam for the compound Corliss engine or engines of its type in order to supply them with the same relative amount of steam. This indicates that a considerably less amount of boiler power would be needed for the more economical engine than for the more wasteful one, and this fact tends to equalize the cost of a power station on employing the different classes of engines.

From actual prices which have been quoted within the last six months the writer feels very certain that an engine of 500-h.p. capacity, of good quality in its respective class, can be purchased and, under ordinary conditions, can be erected complete on foundations for the figures which are given in the following table. A boiler horse power is considered as worth $12 when erected for each class of engines. In view of the recent rise in prices this may be somewhat low, but the results are comparatively true for each class of engine. The figures in the table do not consider real estate, building or chimneys, which would vary largely with different conditions. Despite the fact that engines,

TABLE VII

COST PER HORSE-POWER OF 500-H.P. PLANT

	Boiler h.p. per Engine h.p.	Cost per h.p. in dollars					Cost for 500-h.p. Plant
		Engine	Boiler	Pumps and Heaters	Piping etc	Total per i.h.p.	
Non-condensing Engines							
Simple slide valve	1 135	8 00	13.60	2.00	5.00	28.60	14,300.00
Simple Corliss	0.933	12.00	11.20	2.00	5.00	30.20	15,100.00
Compound slide valve	1.00	11 00	12.00	2.00	5.00	30.00	15,000.00
Condensing Engines							
Compound slide valve	0.75	11.00	9.00	4.00	6.00	30 00	15,000.00
Compound Corliss	0.602	16 00	7.25	4.00	6.00	33.25	16,625.00

pumps, heaters and piping will cost more per horse power for the condensing engines than for the non-condensing engines, the total cost per horse power does not differ greatly for the various classes of engines employed; this is due largely to the fact that a smaller boiler plant is needed with the more economical engine.

Table VII. shows the cost per horse power and also the total cost of the machinery for a power plant of 500-h.p. capacity. It may be remarked that the cost of engines of larger units would be somewhat less per horse power and the cost of those with smaller units somewhat greater per horse power than the results shown in the table.

Taking the fuel consumption as shown by the average results and also the best results in the various tests mentioned, we can compute the yearly requirements in tons per horse power for each class of engine. This has been done in the following table, which is arranged to show the number of tons of 2000 lbs. each required per horse power per day for a day of twelve hours, of eighteen hours and of twenty-four hours. The fuel cost at $2 per ton per horse power year for a day of eighteen hours is taken as a basis of comparison of fuel costs of the various engines which have been tested. A day of eighteen hours is believed to represent fairly well the average length of time which railroad engines are required to operate. It is also believed that $2 per ton is not far from the average price paid for coal by railroad stations in this State. If anything, it is rather below than above the average price, and consequently lessens rather than exaggerates the proportional saving made by the most economical engine.

To the fuel cost of each engine must be added fixed charges of sufficient amount to cover interest and repairs, and this has been assumed to be in each case 8 per cent of the cost. No account is taken of that portion of the operating expense chargeable to employees and oil, for the reason that there is no known reason why such charges should be essentially different for the best or for the poorest engine. The following table shows these various quantities computed for the different classes of engines. The last column in the table shows the sum of fuel costs and fixed charges, and is one which may be taken to represent the proportional yearly cost of each class of engine.

By a study of the results in the latter column some interesting conclusions may be deduced.

First, as to the saving due to condensing water; we have only two results which can be compared to show the value of the condenser; these results are the cost of the compound slide valve non-condensing compared with the average value for the compound slide valve condensing. The results are respectively, $29.54 and $23.76; the saving due to condenser is $5.78, which is 19.5 per cent of the cost of running a non-condensing engine, and 24.4 per cent of the cost of running a condensing engine. The saving would seem to be nearly 20 per cent, for reasons which have been already mentioned, would probably be more.

Second, the average yearly cost of engines of the compound condensing type with the Corliss, McIntosh and Seymour, or Greene valve gear as compared with the simple slide valve engines, show a yearly saving of $14.69 per horse power.

The difference in costs of the power plants considered is $4.65, which is the excess in cost of the compound condensing Corliss type over the simple slide valve non-condensing. The saving in fuel and fixed charges is thus seen to be sufficient in a single year to pay 3.15 times the difference in cost between the cheapest and best power plant. Comparing in the same way the average yearly costs of fuel and fixed charges for the compound slide-valve condensing engine and the compound Corliss condensing type, we find a yearly saving of 5.64 in favor of the better grade of engine. The difference in costs of the two plants is 3.25 in favor of the compound condensing slide-valve engine. Thus, in a single year the saving on the fuel and fixed charges of the better engine as compared with the poorer will pay 1.73 times the difference in costs.

Third, these figures would show that no station can afford to purchase and operate the simple non-condensing engine of any type as compared with the compound condensing engine, and, fourth, that the compound condensing engine of the best type and with improved valve gear such as the Corliss, McIntosh & Seymour and Greene, and one or two other makes, although costing somewhat more, is so much more economical to operate that, taking all things into consideration, it gives much better financial returns than an engine of any other class. These financial returns are so much in their favor that unless other conditions are exceedingly unfavorable these latter engines are the only ones which should be considered in purchasing machinery for power-house work. This general conclusion, that the compound condensing engine of slow rotative speed and with the improved valve gear is much more economical to use than any other type for power-house work, even when fixed charges are considered, is certainly the only one which can be adopted from the average results of the tests which I have quoted. This conclusion is noticeable from the fact that in a comparison of costs of different types of railway engines made by Dr. Charles E. Emery, he concluded that the compound condensing engine of the slide valve type and with cylinders arranged in tandem was, when fixed charges were considered, the more economical engine to use. The tests which I have referred to point to a different conclusion, and indicate that the saving of the better type of engine will many times repay the extra expenditure of costs. In brief, the tests indicate that the engines of the best class are much the better investment.

TABLE VIII

FUEL AND INTEREST CHARGES FOR THE DIFFERENT CLASSES OF ENGINES

Address of the President of the Street Railway Accountants' Association

BY J. F. CALDERWOOD

Gentlemen of the Association: "Know Thyself," that simple injunction carved over the entrance to a temple of ancient Greece—so old that no one knows who wrote it—is a motto which has impressed me as ideally appropriate for this organization, the newest branch of a business, which is at once the effect and the cause in what might be called the latest phase of modern civilization—rapid transit.

The executive head of one of the larger street railway systems of America said recently that the industry had not developed beyond 20 per cent of what might reasonably be expected as the ultimate future of street railway business in America; in other words, that there still remains four times as much to do as has been accomplished in the perfection of the art of carrying the public. If this be true, no small part of the future development must be due to the work of the men who, by analysis of accounts, establish the data for future advancement. Managers are continually balked by new problems, and while the operating department is usually able to answer satisfactorily the question: can this or that be done? it is for the accountant to go further and ascertain what can and what cannot be done profitably; for, in the end, the wisdom of every policy must pass the ordeal of ultimate cost.

Andrew Carnegie, the captain-general of the iron and steel industry, paid this tribute to the calling here represented: "There is not a science or class of men on whom the business of the world is more dependent than the science of accounts and accounting." It is an axiom of modern business on which its success depends—I will go further and say, upon which its very life depends, that of having within it a well-devised system of accounting which will show at all times (with the least labor and the greatest accuracy) its true condition. In the idiom of the street, show me the management of any company, mercantile, manufacturing or transportation, that does not recognize this principle and act upon it, and time will show you its "finish."

More, perhaps, than any other, does the street railway business depend upon, and involve diverse and extraneous conditions, rendering it doubly necessary that a successful management, in order to secure the greatest revenue with a minimum of expense, should be prepared for prompt action and unerring judgment, by careful analysis and minute comparison of the various items of revenue and expense through its accounting department.

Pursuant to a general desire on the part of those who had struggled single-handed and alone through the maze of unsystematic street car bookkeeping in a desperate effort to supply these much needed data, a few accountants met in Cleveland, March 24, 1897, for the purpose of promoting an organization which would bring together, for exchange of ideas, those engaged in the ac-

counting departments of street railways. Many of you will remember that paper, fruitful of discussion, read by C. N. Duffy, upon the "Standardization of Street Railway Accounts," which, by common consent, became the chief subject of discussion at that meeting, as it has been ever since the foundation of the chief work of this association.

For the purpose of preserving the continuity of the developments I will remind you briefly of the appointment of a committee upon this subject consisting of Mr. Duffy, chairman; W. F. Ham, of Brooklyn, and myself, which reported at the convention held at Niagara Falls in October, 1897. The report of the committee was approved, but the question arose as to the probable action of the railroad commissioners of the various States, since these commissioners in many States, prescribe what system of classification shall be used by the street railway companies reporting to them. As a result of the debate it was decided to continue the committee permanently, its membership being increased by the addition of H. L. Wilson, of Boston, and H. J. Davies, of Cleveland. The permanent committee endeavored during the following year to have meet with it the railroad commissioners of the States which exercise any control over the accounts of street railways, but arrangements could not be made previous to the convention, which met in Boston. A full and complete report covering the matter of uniform accounting was presented at the Boston convention by the committee, and adopted, notwithstanding their inability on account of lack of time to secure the approval of the railroad commissioners.

You will have presented to you, at this meeting, a full report from the committee covering its conference with representatives of the State railroad commissioners, and also of the American Railway Accountants' Association. At this conference Mr. Duffy and Mr. Ham acted for our committee. I take pride in calling your attention to the recognition there accorded the action of our association in the adoption by the conference of the entire system of classification (with a very few minor changes) as prepared and promulgated by our organization. This tribute to our committee is admirably expressed in the language of William O. Seymour, chairman of the committee which reported to the railroad commissioners at their meeting at Denver, Aug. 10 last. Mr. Seymour, in his report, said:

"It was found that the form prepared by the street railway accountants was so much more advanced in its preparation, so complete and full in its details, and so well adapted for its purpose, owing to the familiarity of those who prepared it with street railway accounting, that we deemed it wise to abandon the work which we had commenced, and advise the indorsement and adoption of the form prepared by them."

The recommendation of their committee was adopted by the convention of railroad commissioners, and we have every reason to believe that the same action will be taken by the American Railway Accountants' Association, since its representatives at the conference concurred in the action then and there taken. We have thus established, through our committee, a recognized standard classification of the various items which enter into the three chief elements of street railway accounting, namely: the revenue, the cost of operation and the cost of construction.

This important feature is now substantially fixed, subject, of course, to slight modifications from time to time as new and varying conditions make it necessary to modify slightly the present established classification, and to that end I would recommend the continuance of this permanent committee on the standard system of classification.

While our association has accomplished much by the practical establishment of a permanent classification of accounts, we are far from having concluded the work necessary for a complete system of accounting, such as would be available for purposes of comparison. What we now need and must have before we shall have fulfilled our mission, is the establishment of a unit of comparison. We may have properly classified the cost of maintenance of way, transportation and general expense, and severally and collectively determined the amounts of each for a certain period as compared with another similar period; the comparison of the totals of one period with another may be in the aggregate more or less. This means nothing in itself, unless we can reduce these several sums to a unit of comparison. Now, whether this unit shall be the ratio which each item of expense shall bear to the total revenue, or whether it shall be so much per car-mile, per motor-mile, per motor-hour or ton-mile, is the next great and important question for the association to consider and to settle. To H. C. Mackay has been assigned a paper bearing upon this subject, which will be read at this convention, and we trust he will suggest a solution of this most perplexing proposition. I would recommend the appointment of a committee on the establishment of a unit of comparison. When this is done I shall feel that we are nearing our goal. With the classification and the unit established, the next important feature is a statement blank that will enable the accountants to present, in a uniform, simple and concise manner, the various results and comparisons.

We have established a department of blanks and forms, and to our energetic and persevering secretary, W. B. Brockway, the association is indebted for a remarkable exhibit of the blanks and forms of various street railway companies. These he has arranged and will present with his report, the first important feature, as well as one of the most interesting on the programme for Thursday's session.

I cannot conclude this task without yielding to a duty which I feel to be incumbent upon me at this time. I desire to remind the members of this association that the enthusiastic accountant, charmed with the possibilities for analysis and classification which lie within apparently meaningless statistics, is frequently tempted to indulge in hobbies, which, while pretty enough from the accountant's standpoint, and frequently necessary in part, are worse than useless so far as giving practical information to the management. The ideal accountant wastes no energy upon unnecessary labor. His aim should be to prepare and present to the management only such salient facts as will enable the man in command to make instant comparison upon the three fundamental elements of street railway operation, namely: the revenue, the labor cost and the material cost; all else is subsidiary.

The revenue statement should show, by hours or otherwise, the number of passengers carried, so that the management may be enabled to secure the largest revenue with the least expenditure.

The labor statement should show, in a systematic and comparative manner, the number of men employed and the amount of wages paid in each department, that the management may compare with corresponding periods, and be able to control labor expenditure and keep within a fixed ratio.

The material statement, by showing the kinds, quantity and cost of materials bought and the consumption of the same, enables the management at all times to regulate the stock of material on hand.

I shall be pleased if what I have just said, fragmentary and brief as it must needs be in an address of this character, will create a discussion; if not at this meeting, at some subsequent meeting of our association. I believe we get more out of the "experience-meeting" feature of our gatherings than from the set papers, valuable as they are.

In ending my term as president, I wish to express my especial appreciation of the good work of C. N. Duffy, that perfect type of an aggressive, progressive and intelligent all-around master of accounting and business man, who laid at Cleveland the corner-stone of this structure, and to his worthy associate, W. F. Ham. To these two gentlemen this association is indebted for the larger part of the great work which it has accomplished since its birth, and I hope that this association has only begun in a field of usefulness which broadens as we advance. Purely practical and limited in scope though it be, it has afforded us a vehicle for good fellowship which I have enjoyed quite as much as the professional stimalus and suggestion. I look forward to future meetings with pleasure, and I thank you all for uniform courtesy extended to me since I have had the honor to preside over your deliberations.

Report of the Secretary and Treasurer of the Street Railway Accountants' Association

BY W. B. BROCKWAY

The past year has been an exceptionally busy one in the secretary's office, not alone in the regular work falling to such an office, but to the preparation of the department of blanks and forms, which is explained in the report of that department, to be made Thursday.

Thirty-four companies have been admitted to membership since the last meeting, as follows:

Tiffin, Fostoria & Eastern Railway Company, Tiffin, Ohio.
Omaha Street Railway Company, Omaha, Neb.
Stamford Street Railway Company, Stamford, Conn.
Cleveland City Railway Company, Cleveland, Ohio.
Citizens' Rapid Transit Company, Nashville, Tenn.
Ottawa Electric Railway, Ottowa, Ontario, Canada.
City Electric Railway, Port Huron, Mich.
Fair Haven & Westville Railroad Company, New Haven, Conn.
Milwaukee, Racine & Kenosha Electric Railway Company, Racine, Wis.
North Hudson County Railroad, Hoboken, N. J.
Metropolitan Street Railway Company, New York, N. Y.
Norfolk Street Railway Company, Norfolk, Va.
Tri-City Railway, Davenport, Iowa.
Metropolitan Street Railway, Kansas City, Mo.
Syracuse Rapid Transit Company, Syracuse, N. Y.
Quebec, Montmorenci & Charlevoix Railway, Quebec, Canada.
Union Traction Company, Philadelphia, Pa.
Vicksburg Railroad, Power & Manufacturing Company, Vicksburg, Miss.
North Chicago Street Railway Company, Chicago, Ill.
Savannah, Thunderbolt & Isle of Hope Railway Company, Savannah, Ga.
San Diego Electric Railway Company, San Diego, Cal.

Duluth Street Railway Company, Duluth, Minn.
Glasgow Corporation Tramways, Glasgow, Scotland, England.
Calumet Electric Street Railway, Chicago, Ill.
Brightwood Railroad, Washington, D. C.
Mobile Light & Railway Company, Mobile, Ala.
Butte Consolidated Street Railway Company, Butte, Mon.
Schenectady Railway Company, Schenectady, N. Y.
Central London Railway, London, England.
Third Avenue Railroad Company, New York, N. Y.
The American Railways Company, Philadelphia, Pa.
Alton Railway, Gas & Electric Company, Alton, Ill.
Kansas City & Leavenworth Railway Company, Leavenworth, Kan.
The Albany Railway, Albany, N. Y.

And but two have resigned:

Birmingham Railway & Electric Company, Birmingham, Ala.
Manchester Street Railway Company, Manchester, N. H.

A statement of the growth of the association is as follows:

Companies forming the Association at Cleveland, March, 1897	25
New members reported at Niagara Falls, October, 1897	12
New members reported at Boston, September, 1898	32
New members reported at Chicago, October, 1899	34
Total	103
Withdrawn	3
Total members to be reported Oct. 17, 1899	100

But a new problem of consolidation is confronting us, a problem which is having a tremendous effect upon the whole street railway world, and I would commend to your earnest consideration the suggestions made in the report of your executive committee.

The finances to be reported are:

Balance from Sept. 9, 1899	$51.84	
Received from applications for membership	340.00	
Received from 1899 dues	730.00	
Received from 1898 dues	60.00	
Received from department of blanks	3.91	
Received from bills payable	225.00	
Received from interest on deposits	.27	
		$1,411.02
Expended for salary of the secretary	$200.00	
Expenses of the secretary's office	83.24	
Printing circulars and stationery	96.65	
Postage for reports, circulars, etc	79.03	
Executive committee meetings	46.05	
Stenographer for Boston meeting	105.00	
Printing report of the Boston meeting	224.67	
Printing 1898 report of the standardization committee	74.49	
1898 expenses of the standarization committee	68.50	
Secretary's traveling expenses	156.90	
Department of blanks and forms	157.21	
Bills payable	100.00	
Cash in Home Savings Bank, Toledo, Ohio	19.28	
		$1,411.02

Bills payable		$125.00
Cash in bank	$19.28	
Unpaid dues	30.00	49.28
Deficit		$75.72

Thus, I cannot report the association as having been a dividend payer, but I am sure the results of the work of the committee on a standard system of accounts and the department of blanks and forms, which now has something tangible to offer, will well repay any reasonable stringency which we may encounter. The circulars sent out from the secretary's office to explain the benefits of membership have all resulted in the increase of applications. We seem to have almost accomplished most of the expensive work made necessary by the creation of the departments of standardization and blanks, and eventually we will sail on the smoother waters of "well-to-do."

It is again my bounden duty to express my doubly grateful thanks to all who have in so many ways assisted in the performance of the work of the association. It has all been so cheerful that the thanks are the more heartfelt, and in all true sincerity I say, thank you.

Report of the Standardization Committee of the Street Railway Accountants' Association

The report to the convention of 1899 of the committee on a standard system of street railway accounting consisted of a final draft of the classification and equipment accounts for overhead, underground, third-rail, storage battery and surface contact electric railways, this draft including the amendments agreed upon by the committees on standardization of the Street Railway Accountants' Association, the Association of American Railway Accounting Officers, and the National Association of Railroad Commissioners. This final draft is the same as that printed in the Street Railway Journal for October, 1898, pages 632 to 638, with the corrections embodied in the following report of Chairman C. N. Duffy, presented to the 1899 convention in Chicago.

Chicago, Oct. 18, 1899.

To the Members of the Street Railway Accountants' Association of America:

Gentlemen.—In response to the invitation of William O. Seymour, of the Board of Railroad Commissioners of the State of Connecticut, to attend a meeting at the Manhattan hotel, New York City, on July 11, 1899, to confer with the committee representing the Convention of Railroad Commissioners and the committee representing the Association of American Railway Accounting Officers, for a general discussion upon the subject of a classification of construction and operating expenses of electric roads, your committee begs leave to report that two of the members attended the meeting.

The following gentlemen were present at the meeting: Wm. O. Seymour, member of Board of Railroad Commissioners of the State of Connecticut and chairman of committee on classification of construction and operating expenses for electric roads; Ashley W. Cole, chairman Board of Railroad Commissioners of State of New York and a member of Mr. Seymour's committee; H. M. Kochersperger, Comptroller New York, New Haven & Hartford Railroad Company and a member of committee representing Association of American Railway Accounting Officers; J. D. Green, auditor of disbursements Pennsylvania Railroad Company and a member of committee representing Association of American Railway Accounting Officers; Wm. F. Ham, representing the Street Railway Accountants' Association of America; C. N. Duffy, representing the Street Railway Accountants' Association of America; H. T. Billings, clerk Board of Railroad Commissioners, State of Connecticut.

After a morning and afternoon session, in which the report of the committee on a standard system of street railway accounting, covering the classification of construction and equipment accounts, classification of operating expense accounts, and forms of monthly and annual reports made to the Street Railway Accountants' Association of America, at its second annual convention, held in Boston, Sept. 6-9, 1898, was fully discussed, the following modifications and changes were unanimously agreed to by all the gentlemen present:

1st.—The title of the sub-heading, "Car Service," which includes operating expense accounts numbers 16 to 24, both inclusive, the second sub-heading under the main heading, "Transportation," was changed from "Car Service" to "Operation of Cars."

2d.—The cost of replacing horses lost by death or worn out in service, and the depreciation in the value of horses, was transferred from account No. 30, "Stable Expenses," to account No. 8, "Maintenance of Miscellaneous Equipment."

3d.—The number of operating expense accounts was changed to 38, numbers 1 to 38, inclusive, account No. 39, "Taxes," being eliminated from operating expense accounts, and classified as a "Deduction from Income."

4th.—In monthly report, under "Deductions from Income," the first item is to be "Taxes."

5th.—In annual reports, under "Deductions from Income," the first item is to be "Taxes."

In explanation of the modifications and changes that were agreed to, we beg leave to submit the following:

1st.—Changing the title of the sub-heading, "Car Service," from "Car Service" to "Operation of Cars." It was stated that the title "Car Service" would conflict with a technical term used in the operation of steam railroads, and with an account that steam railroads carry on their books. In addition, it was suggested that the title of the sub-heading, "Operation of Cars," was preferable to "Car Service," and was in uniformity with the title of the first sub-heading under "Transportation," "Operation of Power Plant." Your committee readily agreed to this suggestion, as we both considered not only the objection to the old title founded, but the name of the new title an improvement over the old.

2d.—Transferring from account No. 30, "Stable Expenses," to account No. 8, "Maintenance of Miscellaneous Equipment," the cost of replacing horses lost by death or worn out in service, and the depreciation in the value of horses. The gentlemen criticised the action of your committee in classifying this item under account No. 30, "Stable Expenses," a "General Expense" account, for the reason that they thought that the cost of maintaining horses was a maintenance charge, and should be classified under the same account that carried the cost of maintaining the wagons and harness. They pointed out that the wagons, harness and horses were one, in the sense that the wagons and harness were useless without the horses, and that in their opinion account No. 8 should carry the cost of maintaining wagons, harness and horses, in order to have the classification consistent. In this, your committee thought they were correct.

3d.—Eliminating account No. 39, "Taxes," from operating expense accounts and classifying same as a "Deduction from Income." In view of the fact that under the Inter-State Commerce classification of accounts, the universal standard followed by steam railroads and the position taken by all boards of railroad commissioners throughout the United States who exercise any supervision over the books and accounts of street railways, that "Taxes" are considered a "Deduction from Income" and not an "Operating

Expense Account," and for the sake of bringing about a uniformity of methods and secure the co-operation of the convention of State Railroad Commissioners and the Association of American Railway Accounting Officers, all of the gentlemen representing these two associations being unanimously of the same opinion as to the disposition of "Taxes," and in addition being firmly fixed in their opinion that "Taxes" should not be a part of the operating expenses of a road, your committee agreed to change the classification of operating expense accounts, taking therefrom account No. 39, "Taxes," and treat "Taxes" as a "Deduction from Income," making it the first item under that heading in monthly reports and annual reports.

At the eleventh annual convention of Railroad Commissioners, held in the city of Denver, Aug. 10, 1899, Mr. Seymour, chairman of committee on classification of construction and operating expenses of electric railways, presented his report, in which he reviewed the work of his committee, referred to the meeting with this committee, spoke in the highest terms of the form of classification of accounts adopted by this association, advised its indorsement and adoption by his association, and submitted verbatim the printed report this committee made to the Boston convention, Sept. 6-9, 1898, with the changes and modifications as agreed upon at the meeting held in New York City July 11, 1899, embodied in the printed report.

The Convention of Railroad Commissioners unanimously adopted Mr. Seymour's report, commending it most highly.

Mr. Seymour's report proper has been made a part of this report.

The committee representing the Association of American Railway Accounting Officers, who were present at the meeting held in New York City July 11, 1899, stated that they would report to their association, at its next annual convention, to be held in May, 1900, the result of the conference with the committees from the Convention of Railroad Commissioners and the Street Railway Accountants' Association of America, and that as a committee they would recommend the adoption and use of the standard system of street railway accounting adopted by the Street Railway Accountants' Association of America, with the modifications and changes as agreed upon embodied into the system.

Your committee desire to take advantage of this opportunity to express their appreciation of the hearty co-operation extended to them by the gentlemen representing the Convention of Railroad Commissioners and the Association of American Railway Accounting Officers, for Mr. Seymour's kind words and strong indorsement of the work of this association, as expressed in his report to the Convention of Railroad Commissioners, and also to the members of that association, for their action in unanimously adopting Mr. Seymour's report as presented.

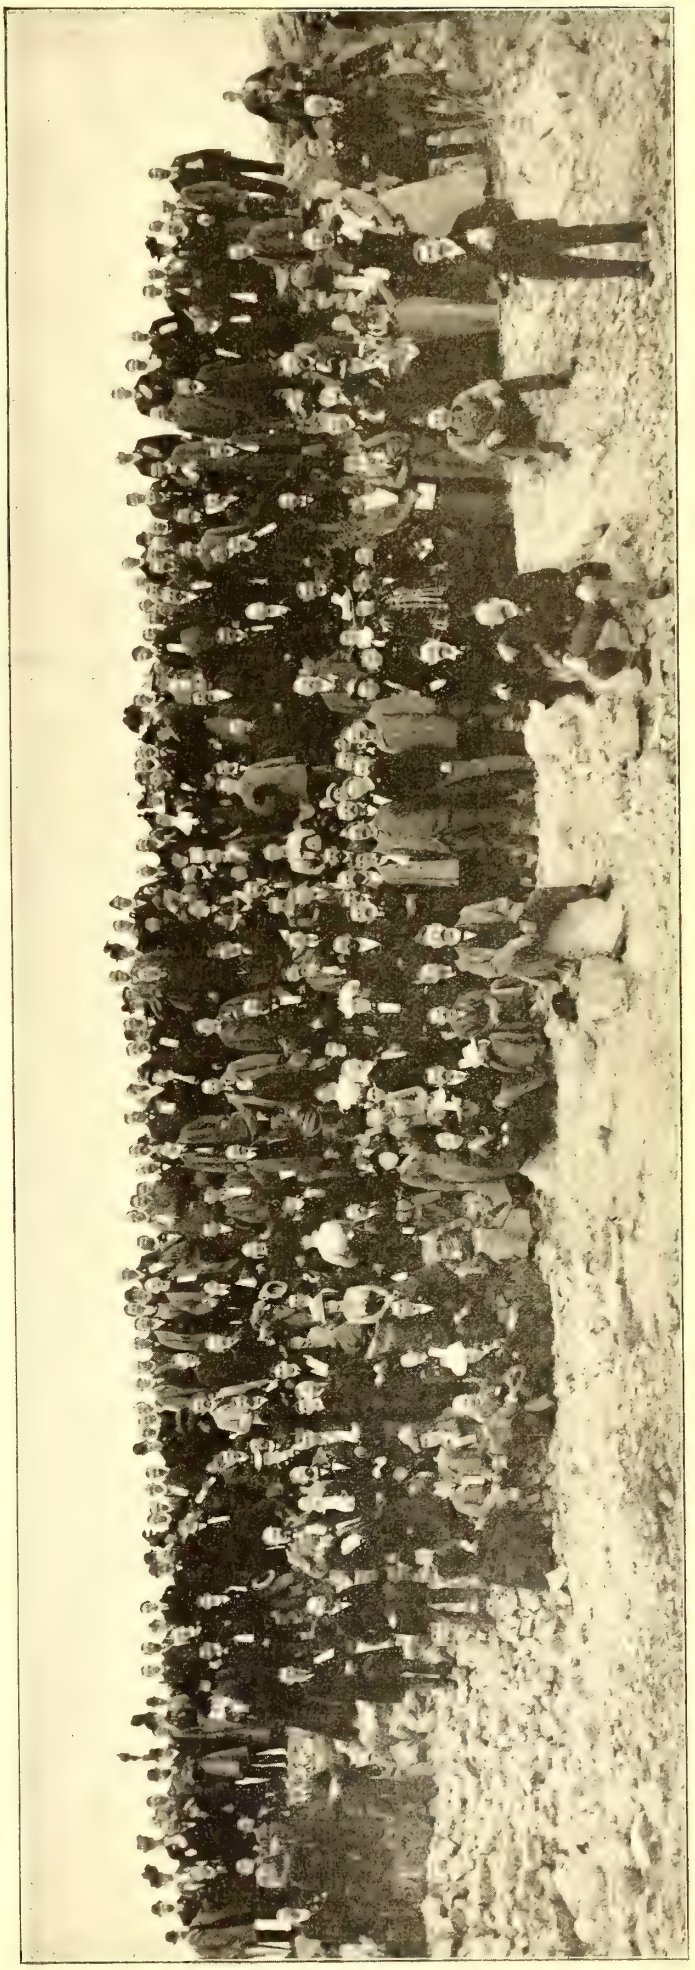
Through the co-operation of the Convention of Railroad Commissioners and the Association of American Railway Accounting Officers, with this association, and in view of what this association has already accomplished, the standard system of street railway accounting adopted by the Street Railway Accountants' Association of America will undoubtedly be used by all street railway companies, thereby securing a uniformity of methods, which has been so much desired and for which we have so earnestly labored.

The classification of accounts accompanying this report embodies all the modifications and changes as agreed upon at the meeting held in New York City, July 11, 1899, and as adopted by the Convention of Railroad Commissioners, at the meeting held in Denver, Aug. 10, 1899. Your committee asks this association to indorse and approve what they have done by ratifying and confirming their action and adopting this report as presented.

Respectfully submitted for the committee,

C. N. DUFFY, Chairman.

Supplementary Report of Committee on a Standard System of Street Railway Accounting



Mr. Duffy also presented a supplementary report in the convention as follows:

CHICAGO, Oct. 18, 1899.

To the Members of the Street Railway Accountants' Association of America:

Gentlemen—In addition to the printed report made by your committee and presented to this convention, we desire to present for your consideration other questions in connection with the standard system of accounting, not touched upon in the printed report.

First—Construction and Equipment Account—"H"—"Investment Real Estate." The instructions classifying this account read, "Charge to this account all expenditures for land and buildings not used in operation of road."

GROUP OF DELEGATES AT CHICAGO CONVENTION, TAKEN WHILE VISITING DRAINAGE CANAL

The committee want it understood that this refers to land and buildings purchased in connection with securing right of way, and real estate used in operation of road, but not a part of either, although incident to the construction and equipment of the road. This does *not* refer to the purchase of land and buildings bought for the purpose of investing surplus funds of the company, which should be charged to a special account; for example, "Surplus Investments." It having been suggested to your committee that the instructions concerning this account were not sufficiently clear or explicit, and that "Investment Real Estate" was not a construction and equipment account, we submit the above for your information.

Second—Monthly Reports—Debiting and crediting the month's proportion of each item under "Income From Other Sources," "Deductions From Income," and "Deductions From Net Income," currently, each month, and charging to accounts Nos. 36 and 37, respectively, the month's proportion of the total annual charge of these accounts, estimating such debits, credits or charges, if the exact amount per month is not known.

The instructions regarding these questions appear to be complete and sufficiently clear and explicit. As far as your committee know, they are fully understood, but they are not always properly carried out. The debits, credits or charges referred to, should be estimated and apportioned monthly, as closely as possible, from the best information obtainable, and the amounts taken up each month by journal entry, so that they would appear on the books. In many instances, these amounts are pro-rated on the monthly report, without having been put on the books at all.

Third—Classification of Material and Supplies—A classification of material and supplies is submitted, because your committee consider it of the greatest importance in connection with the use of the standard system of accounting adopted by this association. Material and supplies have been classified under thirteen departments, A to M, inclusive. The items properly classified under each department, should be alphabetically arranged as they are under each account. In addition, the items should be indexed, showing the department or departments that each item properly belongs to. This detail would have been carried out by your committee, if sufficient time were at our disposal to do the work.

This supplementary report is presented for your careful consideration. We hope that the questions referred to will meet with full discussion, and we will be glad to have the report subjected to any criticism that you may see fit to make.

Respectfully submitted for the committee,

C. N. Duffy, Chairman.

CLASSIFICATION OF MATERIAL AND SUPPLIES.

Department.

A. Material and Supplies for Maintenance of Track and Roadway.
   All material and supplies as classified under Account No. 1, that properly belong *only* to Track and Roadway.

B. Material and Supplies for Maintenance of Electric Line.
   All material and supplies as classified under Account No. 2, that properly belong *only* to Electric Line.

C. Material and Supplies for Maintenance of Buildings and Fixtures.
   All material and supplies as classified under Account No. 3, that properly belong *only* to Buildings and Fixtures.

D. Material and Supplies for Maintenance of Steam Plant.
   All material and supplies as classified under Account No. 4, that properly belong *only* to Steam Plant.

E. Material and supplies for Maintenance of Electric Plant.
   All material and supplies as classified under Account No. 5, that properly belong *only* to Electric Plant.

F. Material and Supplies for Maintenance of Cars.
   All materials and supplies as classified under Account No. 6, that properly belong *only* to Cars.

G. Material and Supplies for Maintenance of Electric Equipment of Cars.
   All material and supplies as classified under Account No. 7, that properly belong *only* to Electric Equipment of Cars.

H. Material and supplies for Maintenance of Miscellaneous Equipment.
   All material and supplies as classified under Account No. 8, that properly belong *only* to Miscellaneous Equipment.

I. Material and Supplies for Shop.
   All material and supplies as classified under Account No. 9, that properly belong *only* to Shop.

J. Fuel (Coal, Coke, Charcoal, Kindling).
   All coal, coke, charcoal and kindling, including coke for welded joints, charcoal for electric line; charcoal, coal and coke for shop; fuel for power; charcoal, coal, coke and kindling for heating cars; coal or coke for heating buildings, and fuel for drying sand.

K. Lubricants and Waste (Oil, Grease, Waste, Rags).
   All oil, grease or other lubricants, and all waste or rags used with lubricants, for shop, power plant, cars, track, wagons, etc.

L. Printing and Stationery.
   All printing and stationery of every description, including tickets, transfers, legal papers, signs, posters and other advertising matter.

M. Miscellaneous Material and Supplies.
   All material and supplies as classified under Accounts Nos. 14, 21, 22, 23, 24, 28, 29 and 30, that properly belong *only* to those accounts, and all material and supplies *not* classified specifically under Departments A, B, C, D, E, F, G, H, I, J, K or L.

The following is a list of some of the items that it is proper to classify under Department "M."

Arc lights and fixtures.
Babbitt (metals).
Badges (employees').
Batteries (for car bells).
Bedding (stable).
Bell cord.
Belting.
Blankets (stable).
Bolts.
Brass (metals).
Brick.
Brooms.
Brushes (car washing).
Brushes (flue).
Brushes (generators).
Brushes (horse).
Brushes (motors).
Brushes (scrubbing).
Buckets.
Carbons (arc light).
Cement.
Chamois skins.
Conductor's books.
Conductor's punches.
Copper (metals).
Cotters.
Curry combs.
Emery cloth.
Feather dusters.
Feed (stable).
Fire buckets.
Fire extinguishers.
Fuses (cars).
Garnet paper.
Globes (arc light).
Horse shoeing supplies.
Hose.
Iron.
Lamps (incandescent).
Light { (lanterns, oil, wick, torches, candles, incandescent lamps).
Lumber.
Matches.
Medicine (stable).
Metals (babbitt, brass, copper, etc.).
Mops.
Nails.
Nuts (for bolts).
Oil cans.
Packing (for engines).
Painting material { (linseed oil, turpentine, varnish, white lead, painter's brushes and supplies).
Paving material.
Pokers (car stoves).
Polish.
Portable registers.
Rags.
Rivets.
Salt.
Sand.
Sandpaper.
Screws.
Shakers (car stoves).
Shovels (car stoves).
Soap.
Spikes.
Sponges.
Sprinkling cans.
Steel.
Stone.
Stove blacking (car stoves).
Tape (insulating).
Tools (hand).
Towels.
Trolley rope.
Uniforms.
Washers (iron).
Washers (car washers).
Waste cans.
Water gauge glasses.
Wire.

Respectfully submitted to the Street Railway Accountant's Association of America, by committee on a standard system of street railway accounting. C. N. Duffy, Chairman.

Annual Convention of the Pennsylvania Street Railway Association

The regular annual convention of the Pennsylvania Street Railway Association was held at the Stevens House, Lancaster, Oct. 11 and 12. In the absence of President Silliman, Vice-President W. B. Given introduced Simon Schissler, Mayor of Lancaster. Mr. Schissler welcomed the delegates to the city, and the response to his address was delivered by J. H. Stedman, in behalf of the association.

The roll-call followed, showing the following active members of the association were represented: Altoona & Logan Valley Traction Company, Harrisburg Traction Company, Lebanon Valley Traction Company, Pennsylvania Traction Company, The Scranton Railway Company, Schuylkill Traction Company, United Traction Company (Reading), Union Traction Company (Philadelphia), Wilkesbarre & Wyoming Valley Traction Company, Williamsport Passenger Railway Company, York Street Railway Company.

The associate members and others in attendance represented the following: J. G. Brill Company, Philadelphia; General Electric Company, Philadelphia; Pennsylvania Steel Company, Steelton; Lobdell Car Wheel Company, Wilmington; Westinghouse Electric & Manufacturing Company, Philadelphia; McKee, Fuller & Company, Catasqua; Philadelphia Car Wheel Company, Philadelphia; Pittsburgh Car Wheel Company, Pittsburgh; Pennsylvania Car Wheel Company, Pittsburgh; Providence Engineering Works, Providence; Street Railway Journal, New York; Smith, Wallace & Bonta, Buffalo; Jackson & Sharp Company, Wilmington; Lykens & Williams Valley Street Railway, Lykens; J. H. Stedman, transfer expert, Rochester; York Car Brake Company, York.

Three papers were read, one on "Street Railway Trucks." by W. H. Heulings, Jr., of the J. G. Brill Company; one on the "Railway Engine of To-day, a Combination of the Principles of High

Speed and Corliss Practice," by W. P. MacKenzie, assistant manager of the Harrisburg Foundry & Machine Works, and one on "Track Construction," by Frank Silliman, Jr., general manager of the Scranton Traction Company.

MR. HEULINGS' PAPER

Mr. Heulings dwelt upon the necessity of good trucks and stated that even comparatively light car bodies, if mounted upon rough riding trucks, will pound to pieces the best roadbed and twist and bend the heaviest rails more or less out of shape within a surprisingly short length of time. He said that this result had been reached within two or two and a half years on roads within his knowledge, where only moderate speeds were used, and where the car bodies were quite small. The first electric truck introduced upon street railways was of the four wheel non-pivotal type and was a natural development of the old horse car running gear. He described what he considered the proper construction which included a solid side frame, preferably forged, making each wheel piece a single bar, and with the two wheel pieces connected by heavy end irons. This makes the truck a self-contained motor vehicle with sufficient strength to support the machinery and haul the trailer if necessary. The springs are an important feature and the writer recommends the use of eight journal box springs, and placing the car springs on the solid frame. Of the latter springs, the outer springs should be half elliptics, those on each side of the jaw, spiral. Although numerous attempts have been made to secure equalizing four-wheel trucks, the speaker thought that these attempts had been unsuccessful. He also said that most of the destruction of street railway tracks comes from badly constructed trucks and not from any heavy trucking which goes over them. He doubted whether four-wheel cars are suitable for any service on modern street railways and strongly recommended double truck cars, claiming the cost of propulsion by steam or electricity varies according to the number of units rather than their size, and is practically independent of the load carried. Moreover, the four-wheel truck, whether of large size or small, should not be run at a high speed because its destructive power increases in proportion to the square of the speed.

Mr. Heulings then discussed the maximum traction truck and stated that a maximum traction car requires no more power for its operation than a four-wheel car. To fortify this assertion he cited the case of the New Orleans Traction Company, which, in 1894, contracted with the Louisiana Electric Light Company to purchase power for its cars at a given rate per car per day. The fact of the traction company introducing maximum traction truck cars was the foundation for litigation brought by the light company, which claimed more compensation to cover the increased consumption of electricity. The traction company's engineer, B. Willard, and the light company's engineer, J. B. Craven, with Walter H. Knight, then of the General Electric Company, conducted a series of tests. Their report was: "We cannot find that the 22-ft. cars on maximum traction trucks consume any more power than the ordinary 18-ft. car bodies on single four-wheeled trucks, such as used on some of the New Orleans Traction Company's lines." Experiments by the Consolidated Traction Company, of Jersey City, showed that the repairs to motors and trucks varied directly as the number of motors and was independent of their size, that the eight-wheel car had a repair account practically twice as large as that of the four-wheel cars. The maximum traction truck permits the use of two motors to the car. It carries a longer and heavier car body and without increasing the weight on the driving wheels over the weight on the wheels of a four-wheeled car, allows the whole weight of the car body to be increased by 33 1/3 per cent.

Ample traction is secured with this truck for the most rapid running, as shown on the Washington, Alexandria & Mt. Vernon Railway, where maximum traction trucks are running at a speed of 40 miles an hour. Another advantage of these trucks over those with four wheels of equal size, is that the car can be brought so low that a single step of usual height gives access to the platform. For high speed service he recommended the Brill "perfect" truck, which has been described in these columns.

From this truck the company has developed the No. 27-G truck, especially for city and suburban use. The No. 27-G truck has four motors, an inside brake and so short a wheel base that it can be used on cars which have to pass short city curves. The swing of the wheels is so short as to make it possible to use them under cars of ordinary width without unduly raising the car body. The equalizer is replaced by long half elliptic springs which also take the place of the elliptics on the spring plank. The four motors employed give the car the greatest possible tractive force and fit it for running at any desired speed. For certain purposes it is possible to modify this truck in such a way as to make it perform many of the functions of the maximum traction, using only one motor per truck. In this case the motor is carried outside the axle, thus bringing a considerable increase of weight upon the driving wheel while the center bearing and center radiation is retained. The spring links, the swing motion and the perfect equalization, three sets of springs, together with journal springs of ample size are features which are retained and which together are the reason for its exceptionally easy motion. The "perfect" truck has shown itself capable of meeting a surprisingly large variety of conditions. At all times it retains its characteristic ease of riding.

While Mr. Heulings had no figures to present relative to the diminished flange wear of wheels in these trucks, he stated that owing to the softening of the side motion by the spring links, little pressure is brought upon the flanges. The truck may be forced violently from side to side by the irregularities of the track, yet so perfectly is the body hung that it only follows the truck slowly or allows the truck to move without itself moving at all. Incidentally in the construction of this type of truck great gain was made in strength. Instead of transmitting the weight of the car body through the transoms to the center of the wheel piece and then from the wheel piece out toward the spring pockets, a considerable distance, in the present case the weight where the spring links throw it upon the wheel piece is but a short distance from the jaws. The wheel pieces are consequently subjected to very little strain and the truck is much stronger in consequence. In fact, getting out of square from the strains set up in running ought to be and is practically unheard of.

MR. MACKENZIE'S PAPER

Mr. MacKenzie objected to the prevalent designation of engines as "high speed" and "low speed," and prefers the terms "short stroke" and "long stroke," for the short stroke engine is often a low speed engine, having a less piston travel per minute, although the rotative speed is higher. In the short stroke engine the steam is admitted to the cylinder much oftener than in the long stroke; there is therefore less opportunity for the cylinder walls to cool, and consequently less cylinder condensation occurs. The economy of this, however, is somewhat offset by the usual higher temperature of exhaust and greater clearance space necessary. These last, in turn, however, became of less importance when a condenser is used or when the exhaust steam is utilized for heating, which are conditions very generally found to-day.

The usual type of governor employed with this engine is an automatic shaft governor.

Corliss or long stroke engines have, in the matter of steam distribution, undoubted advantages, and in their sphere give satisfactory results, although this sphere is limited. As built to-day, they are practically the same in the arrangement of their mechanism as the original one from which they derive their name. The old vacuum dash pots and tripping device remain, and it is not considered practical to speed the engine much over 90 r.p.m., or at the most 100 r.p.m. The old style Corliss engine also takes up more space and is more noisy than the modern short stroke engine. With the high rotative speed of the latter, smaller diameter fly wheels are possible, and with the same rim velocity the danger of bursting wheels is reduced, as it is easier to make the smaller castings perfect. The short stroke engines also regulate closer on account of their use of an inertia shaft governor. Compared with the long stroke engine, however, they are usually less economical in coal consumption per i.h.p.

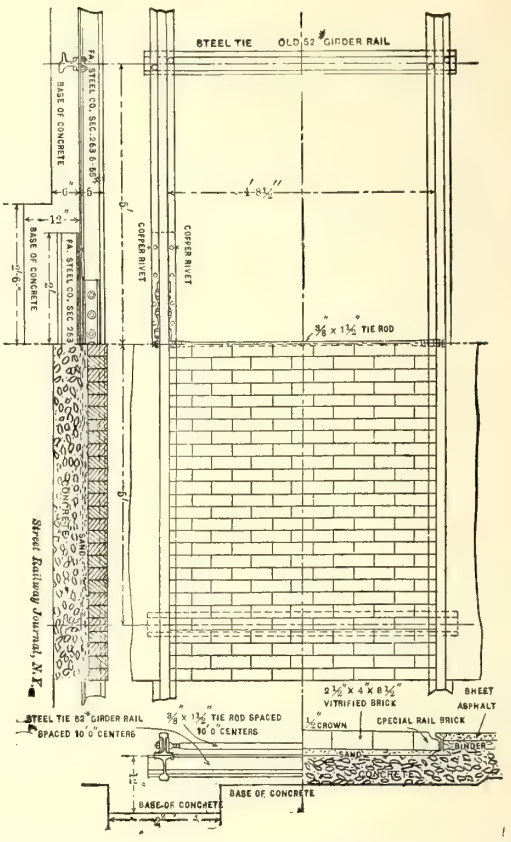
The writer then stated that three or four styles of combination engines designed to embody the advantages of both the short stroke and Corliss engine had been placed on the market, and of these described that manufactured by the Harrisburg Foundry & Machine Company.

Probably the most novel feature in this engine is the steam accelerated valve gear, so-called because of auxiliary steam cylinders, so arranged as to give a most positive and instantaneous cut-off to the steam admission valves. The engine is provided with two eccentrics, each having unvarying motion, being fixed to the shaft. That eccentric which operates the mechanism controlling the steam valves is connected to a rocker arm on the side of the engine frame, and from this point a connecting rod transmits the motion to two levers, which are pivoted to the valve stem brackets. On the outside of these levers protrudes a small steel shaft, at the end of which is a multiple sided steel block made with renewable wearing surfaces. To the outer end of each valve stem is securely keyed another lever, through which passes a small rod. To the lower end of this is attached a hardened steel toe-piece, with a face to correspond and engage with the multiple sided steel block above alluded to. This toe-piece is actuated by a cam by means of a shaft and lever; the cam is pivoted upon the valve stem bracket, and receives its motion from a rod connecting through a bell crank to a centrally balanced centrifugal inertia governor. By a connecting link the cams are made to operate in unison. The governor is mounted upon a heavy bracket shaft, securely fastened to the side of the engine frame and is driven by a belt from a pulley keyed to

the engine shaft. From the mechanism above described it will be apparent that if no auxiliary motion were provided, the cut-off of steam in the cylinder would occur in a hesitating manner, due to the slow travel of the eccentric through its arc of motion. It is this difficulty that the steam acceleration overcomes, as a brief description will make evident. Attached to the heaviest portion of the valve stem bracket is a frame having two small cylinders, one intended for air and the other for steam. The piston rod common to both connects at a central point by a sliding block to a lever, extending upwards and keyed to the valve stem. The auxiliary steam cylinder is supplied by steam direct from the boiler. This auxiliary cylinder has no piston but the piston rod common to both cylinders passes into the steam end by means of the ordinary stuffing box, and thus presents only the end sectional area to the pressure therein. No new steam is required nor exhaust necessary, hence no losses from this source are possible. The constant pressure in the auxiliary steam cylinder compels contact of the toe-piece and multiple faced block, which continues until released at a position determined automatically by the centrifugal inertia governor. The steam pressure then instantly impels the steam valve to positive cut-off, instead of allowing the more leisurely action of the eccentric alone. This steam accelerated motion of the cut-off device is arrested by the compression of air in the cylinder provided for that purpose, forming a cushion which prevents all jar, vibration or damage.

The exhaust valves of the engine are controlled by a motion beginning at the outer eccentric, which, as already stated, is fixed to the crank shaft and has therefore a constant motion. Through the medium of a rocker arm and two connecting rods, this motion is directed to the long arm of a bell crank attached to the valve stem bracket a little to one side of its center. To the short arm of this bell crank is attached a link, which transmits the motion to a lever keyed to the valve stem; the valve being thus oscillated by the compounding of the angularity of the several levers gains a greatly to be desired quickness of motion at the points of release and closure. The forward exhaust valve is connected to the other by a common link so that they work in harmony with one another.

The governor is of the centrifugal inertia type and is centrally balanced, which balance is maintained in all positions of cut-off, the governor operating with equal ease and isochronism from zero to 75 per cent cut-off. The rotative speed of the governor is about three times greater than that of the engine, insuring unusual sensitiveness. The variation in speed by the use of this style of governor, no matter how sudden or great the change of load may be, can be easily kept within the very close bounds of 1 per cent, and under exceptional circumstances, where the service demands it, the range can be reduced as low as ½ per cent.

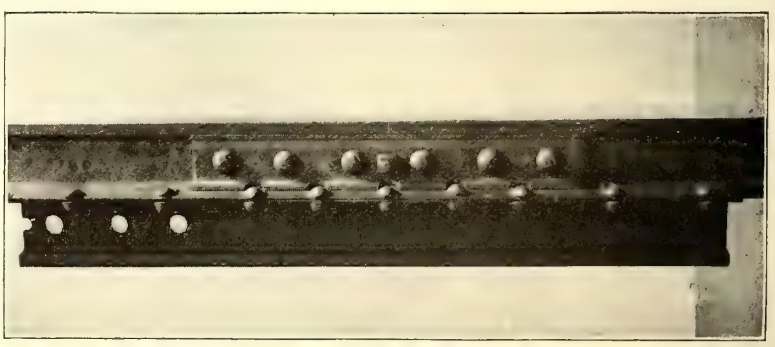


The form of valve used is similar to Corliss practice, being a multi-ported rotary valve, by the adoption of which the clearance spaces are very much reduced, over those usually found in high speed practice, thus resulting in improved economy.

In summary, Mr. MacKenzie claimed for the type of engine described, the following combination of virtues: Compactness, simplicity, ease of access, quiet running, great range of speed, smaller diameter fly-wheels possible, when direct-connected lower first cost of generators as rotative speed can be comparatively high, low friction losses, almost perfect regulation, and economy equal to the best known practice.

MR. SILLIMAN'S PAPER

In the design of a construction of track that has been used in Scranton on the lines of the Scranton Railway Company, to a considerable extent during 1899, the two main points sought were a rigid joint without the use of unduly heavy rail between the joints and the employment only of such materials as are practically imperishable



The rail used has been a 5-in. high T-rail, having a base of width equal to the height of the rail, and weighing 57 lbs. per yard, with a stem ⅜ in. thick, and having parallel sides. The joint consists of the ordinary six-bolt joint that has been heretofore furnished with such rail, except that it has been rolled to a little heavier weight. Entirely in addition to this joint, is what is claimed to be a novel feature of it, and that is, a 4 ft. long piece of the same section of rail, inverted and placed under the joint, and secured to it by eighteen ¾ in. rivets, which are driven by a pneumatic bridge riveter in the field. Four of these rivets are of copper, and constitute bonds of the joint. As long as the rivets hold tight, this makes a rail at the joint, that is 10 ins. in depth, securing a girder as deep as the heaviest sections of rail that are rolled. In between the joints, it is, of course, not necessary that the rails should be as heavy, and the great waste in the ordinary 9-in. or 10-in. rail track construction, is owing to the fact that there is so much of this great weight of rail used in between the joints, in order that the joints themselves may be of the necessary stiffness and rigidity. The rails being in 60-ft. lengths, make the economy of this construction still greater, due to this feature. Through the middle of each joint is a tie-rod, and every 10 ft. of track contains a tie-rod. Ten feet apart and intermediate between the tie-rods are ties, which are made, in the case of the Scranton company, of a 52-lb. girder section that has been taken up from old track. Almost any rail section may be used for these that has a sufficient width of base to allow the bolt holes to be drilled in it. The ties are bolted to the rails, and not riveted. The tie-rods are the same as

SECTION AND PLAN OF TRACK CONSTRUCTION, SCRANTON

those that have been in use for many years, being flat bars, so as to interfere as little as possible with the pavement.

This metal part of the construction having been assembled, as heretofore described, and surfaced and lined on blocks on a bed prepared by grading and by rolling with a 10-ton roller, is filled under with a sub-structure of concrete, having a uniform thickness of 6 ins., except at the joints and at the ties, where the thickness of the concrete is increased to 1 ft. The work of concreting

SIDE VIEW OF RIVETED JOINT EMPLOYED IN SCRANTON

having been completed, the whole is allowed to stand for a week if possible, and for at least five days, before any traffic is allowed on the rails. The top of the concrete is the bottom of the rail, of course, and this leaves a height of 5 ins. from the top of the concrete to the level of the surface of the street.

The pavement between the rails is made of brick, which are 4 ins. in width, and this leaves 1 in. for sand on top of the concrete. The brick next to the rail are of special form, made so that the surface of the pavement is the same as the surface of the head of the rail, with the exception of a groove for the flange along the

inside of the rail. On the outside of the rail, plain brick are used, which come up against the head of the rail, and the space between the head and the base, out to a line flush with the head of the rail, is filled with cement mortar. The whole brick pavement is grouted with cement grout, and rolled to a level surface and uniform crown by a 5-ton roller, running on the rails of the track.

The work of construction is very much facilitated by the machinery used and the uniformity of the work is, no doubt, very much greater than in the case of hand work. The concrete mixer is mounted on a low car, and driven by a No. 3 Westinghouse street car motor, while the pneumatic riveter is mounted on a car having on it a derrick for handling the riveter, and a motor-driven air compressor for furnishing the air.

VIEW OF BALLAST CAR

VIEW OF COMPLETED STREET

DUMPING BALLAST FROM CAR

RIVETING RAIL JOINTS BY PNEUMATIC POWER

This construction has given a great deal of satisfaction to the authorities of the city, and seems to be very popular with those who have to drive on streets where tracks are located. More can be said of the durability of this construction in the course of a few years time, but it being entirely free from such perishable material as wood, should last a long time. The lightness of the rail is compensated by the fact that it is supported under every inch of it. Additional width to the base of the rail would still further improve the construction.

OFFICERS

Officers for the ensuing year were then elected as follows: President, W. B. Given, Pennsylvania Traction Company, Lancaster; first vice-president, E. C. Felton, Harrisburg Traction Company, Harrisburg; second vice-president, E. H. Davis, Williamsport Passenger Street Railway Company, Williamsport; treasurer, W. H. Lanius, York Street Railway Company, York; secretary, S. P. Light, Lebanon Valley Traction Company, Lebanon. Executive committee—W. B. Given, Frank Silliman, Jr., S. P. Light, W. H. Lanius, John Rigg.

The place selected for the next meeting was Pittsburgh, Pa., and the time the third Wednesday in September, 1900.

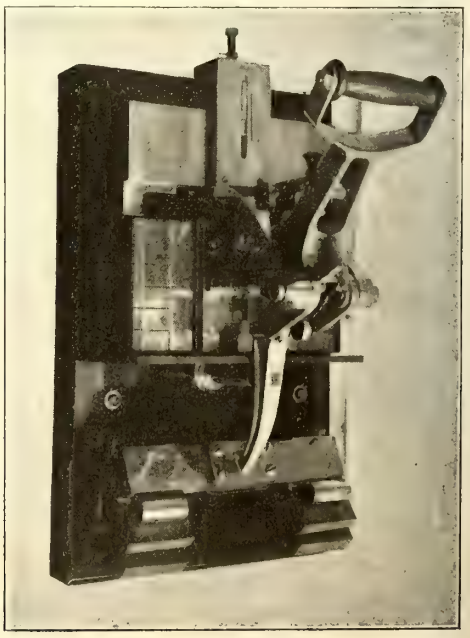
The Exibit of Street Railway Apparatus at the National Export Exposition

The National Export Exposition, which opened in Philadelphia, Sept. 14, and closes Nov. 30, is being utilized by many manufacturers of mechanical appliances for the exploitation of their products in foreign lands. Leaders, as we have been, in the field of mechanical traction, devices and materials for use in this field are on the foremost wave of the rush of export business that seems to have set in since the Spanish-American war. Many companies do not exhibit, for the reason that the home demand is at present so great and the price of raw materials so high that efforts to obtain export orders are discouraged, but others, realizing that this is a temporary condition, are making extensive exhibits, some of which are described below.

In the line of electrical apparatus the most general exhibit is that of the General Electric Company, of which company the foreign department has fitted out an extensive booth in the Exposition. The apparatus shown is largely for central-station service or general supplies, there being no street railway material proper in the exhibit.

The Standard Underground Cable Company, of Pittsburgh, has a number of show-cases, one of which contains samples of its products especially manufactured for street railway work. Among these are its cables, cable terminals, Conner junction boxes, etc.

EXHIBIT OF GENERAL ELECTRIC CO. AT PHILADELPHIA



Another exhibit of wires and cables is that of the John A. Roebling's Sons' Company, whose booth at the Export Exposition is fitted out with the same apparatus and in the same general style as was its exhibit at the New York Electrical Show, this apparatus having become a sort of permanent exhibit, which is sent from exhibition to exhibition. One new feature of the collection is the samples of work done at the company's new rubber mills, which were recently started in Trenton, these mills already consuming 1000 lbs. of Para rubber per day. As usual, the company's rail bonds are well represented.

The Reconstructed Granite Company, of New York, has an attractive exhibit of all its various lines of manufacture. In the Street Railway Journal for May, some particulars were given of this remarkable material, especially with reference to its use for third-rail insulators. Since then the company has largely extended its manufactures, so as to cover a great variety of uses for electric railways, such as rheostat blocks, arc deflectors, fuse boxes, cut-outs, etc., for controllers and motors, to be used in place of porcelain and vulcabeston, and claims for it not only the highest insulating properties and great durability, combined with low cost, but also that copper will not deposit upon the surfaces, and that it cannot be injured by fire, frost or sudden changes of voltage or temperature. The company is having considerable success in introducing this material upon various street railway systems. In addition to showing reconstructed granite in these various forms, the company exhibited a line of glass-lined electrical conduits and chemical ware, which attracted much attention. A panel of the company's exhibit of reconstructed granite is illustrated in this connection.

The Cutter Company, of Philadelphia, has a large display board, on which is mounted one circuit breaker of each different type manufactured by the company, including even some freak combinations. The most interesting breaker of the collection is a mammoth one of the new laminated-wedge type, specially designed for street railway service. This particular one is the largest yet made by the company, and is rated at 4000 amps., its range of operation being from 2000 amps. to 5000 amps. This breaker has a main contact with finely laminated leaves wedged between oblique contact blocks by a toggle joint operated by the handle. The force required to close this breaker is much less than that

THE NEW BRILL CONVERTIBLE CAR

CUTTER 4000 AMPERE BREAKER

necessary for the older types of knife and jaw breakers of much smaller capacities. Incidentally, too, the weight of the breaker is greatly reduced by the more compact arrangement and the greater number of points of contact over a given area of contact surface. The carrying capacity of the breaker is so much improved by the new principle involved that it runs cooler than do the older types, in spite of the reduced area for radiation of heat. The main contact of this breaker is shunted by a secondary copper contact, designed to form a better short circuit around the main contact than would ordinary carbon contacts, and this secondary copper contact is in turn protected by a tertiary carbon contact of ample size for for the enormous current the breaker is desired to carry.

In the line of materials and supplies, the Ajax Metal Company, of Philadelphia, has a booth made entirely of bars of babbitt metal and containing samples of the trolley wheels and harps, journal brasses, steet car fittings, etc., turned out by this company. A similar exhibit is that of Merchant & Company, of Philadelphia, containing, as it does, samples of the firm's extensive line of solder, babbitt and other alloys. In addition, the booth is covered with a roof fitted with the firm's Star ventilator, over which there is arranged an artificial rainfall. The interior of the ventilator is illuminated with incandescent lamps, designed to show that no water comes through. Another exhibit of materials valuable in street railway work, although not mechanical in character, is that of the Joseph Dixon Crucible Company, which, as usual, makes an extensive showing of its graphite products. As this material does not adapt itself to very extensive exhibit decoration, the space occupied is elaborately fitted out with handsome furniture, palms, etc. Prominent in the exhibit is one lump of Ceylon graphite exactly as mined, weighing 270 lbs. This is said to be the largest single piece of graphite in this country.

Of track materials and accessories there are many interesting lines shown. The Continuous Rail Joint Company, of Newark, has on exhibition its product consisting of an extended angle or tie-plate carried down below the foot flange of the rail, forming a base-plate and girder. The samples shown at the Exposition were made by the Illinos Steel Company, and rolled nine times, giving them a high tenacity, which is forcibly illustrated by pieces twisted and bent when cold to fantastic distortions. The Diamond State Steel Company also makes an exhibit of its rails, tie-plates, angles, foot-plates and other special street railway steel work. Another exhibit in that line is made by the firm of Wm. Wharton, Jr., & Company, of Philadelphia, who show their specialties in the line of street railway switches, frogs and crossings with manganese steel points. Much of the work shown in this company's exhibit is cast-welded, the various parts of a diagonal cross-over being shown cast-welded together. The firm also shows sections of the various types of rails which it handles, as well as models of derailing and unbroken main-line switches for street railway work.

The Philadelphia Railway Track Equipment Company makes its exhibit, which has become a familiar one to visitors to railway conventions. The exhibit shows the special points of the company's system, the series of under and over-lapping half sections, the rail-head being rolled separate from the foot flange, with staggered joints and tie-bars, which lock the whole together.

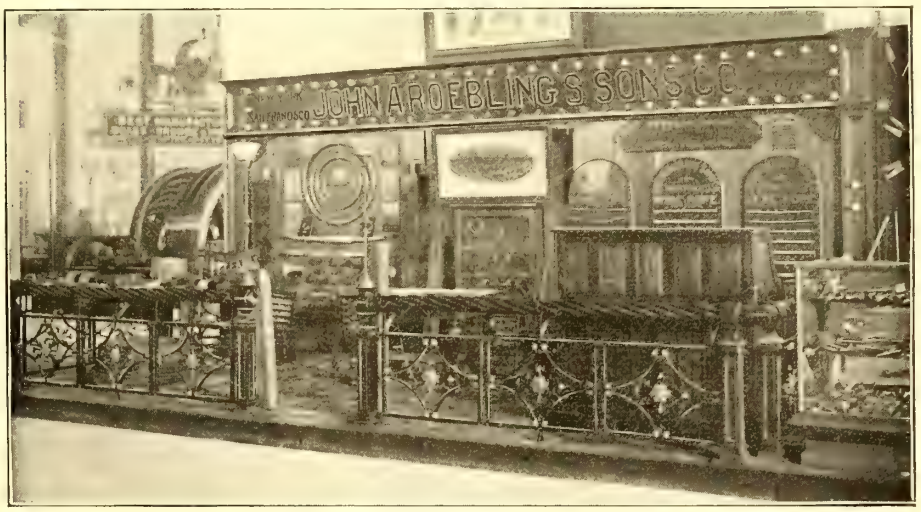


EXHIBIT OF THE ROEBLING CO.

Of cars and trucks, the most extensive exhibit is that of the J. G. Brill Company, in the Transportation Building. The most conspicuous feature of this exhibit is Brill's convertible car. In the form shown at the Exposition, this car differs somewhat from its predecessors in having movable panels at its sides covered with an oxidized copper sheet, the panels being finished inside with wood veneer. The rest of the exhibit consists of Brill's sprinkler and trucks of four different styles, the Perfect, the Universal, the Eureka Maximum Traction Pivotal and No. 21-E. The convertible car is fitted with a Providence fender. The Consolidated Car Fender Company has also an exhibit in the main building, consisting of its handsomely-finished full-sized brass model of fender of the 1900 style. Another duplex car is also shown in the Transportation Building, made by the Duplex Car Company, a description of which is hardly necessary in these pages.

Of car wheels, there are two interesting exhibits, one that of the New York Car Wheel Works, of Buffalo, and the other the Whitney Car Wheel Works, of Philadelphia.

EXHIBIT OF THE STANDARD UNDERGROUND CABLE CO.

EXHIBIT OF THE RECONSTRUCTED GRANITE CO.

STREET RAILWAY MEN AT THE CONVENTION

Representatives of Member Companies

Alton, Ill.—George D. Rosenthal, electrical engineer, Alton Railway, Gas & Electric Company.

Anderson, Ind.—Charles L. Henry, general manager; Charles Berry, superintendent; Albert S. Richey, electrical engineer; W. C. Simpson, director, and Frank H. Schlater, chief bookkeeper, Union Traction Company.

Atlanta, Ga.—E. Woodruff, president; J. R. Gordon, engineer, Atlanta Consolidated Street Railway Company. E. Woodruff, president, and J. P. Smedden, engineer, Atlanta Railway Company.

Augusta, Ga.—C. O. Simpson, secretary, Augusta Railway & Electric Company.

Aurora, Ill.—D. A. Belden, general manager, and C. C. Quackenbush, superintendent, Aurora Street Railway Company.

Atchison, Kan.—J. A. Bendure, general manager, Atchison Railway, Light & Power Company.

Bay City, Mich.—E. S. Dimmock, general manager, and W. R. Morrison, assistant general manager, Bay Cities Consolidated Railway Company.

Binghamton, N. Y.—G. Tracy Rogers, president, Binghamton Street Railroad Company.

Birmingham, Ala.—J. B. McClary, general manager, Birmingham Railway & Electric Company.

Boston, Mass.—Charles S. Sergeant, second vice-president; H. L. Wilson, auditor; J. H. Studley, Jr., and John Balch, assistant engineer, Boston Elevated Railway Company.

Bridgeport, Conn.—Andrew Radel, president, and James Butler, superintendent, Bridgeport Traction Company.

Buffalo, N. Y.—R. E. Danforth, superintendent, Buffalo Railway Company. George Chambers, superintendent, Buffalo Traction Company.

Brooklyn, N. Y.—J. H. Vander Veer, superintendent of shops; J. S. Breckenridge, chief engineer; F. H. Shepard, elevated equipment, and Giles S. Allison, sales agent, Brooklyn Rapid Transit Company.

Camden, N. J.—William S. Scull, president, and W. E. Harrington, general manager, Camden & Suburban Railway Company.

Charleston, S. C.—Nicholas S. Hill, Jr., general manager; P. J. Balaguer, auditor, and G. B. Allen, director, Charleston Consolidated Railway, Gas & Electric Company.

Chester, Pa.—Henry C. Moore, vice-president, and R. H. Beach, director, Chester Traction Company.

Colorado Springs, Col.—A. L. Lawton, general manager; F. C. Lawton, superintendent, Colorado Springs Rapid Transit Railway Company.

Chicago, Ill.—E. R. Gilbert, general manager; A. E. Davies, superintendent, Chicago Electric Traction Company. John McNulta, receiver; John Farson, president; H. M. Sloan, general manager; Edward H. Harrison, auditor; George H. Binkley, engineer; W. A. Harding, master mechanic and electrician, Calumet Electric Street Railway Company. Charles T. Yerkes, president; John M. Roach, general manager; F. E. Smith, auditor; John Millar, master mechanic, Chicago Consolidated Traction Company. D. G. Hamilton, president; Robert McCulloch, general manager; T. C. Penington, treasurer; F. R. Greene, secretary; G. O. Nagle, superintendent; George W. Knox, electrical engineer; A. C. Heidelberg, assistant superintendent; C. N. Duffy, auditor, Chicago City Railway Company. William Walmsley, superintendent; Benjamin Dawson, electrician, South Chicago City Railway Company. George A. Yuille, second vice-president; J. C. Moore, secretary; M. B. Orde, assistant treasurer; James R. Chapman, electrical engineer, Chicago Union Traction Company.

Cleveland, Ohio—Charles W. Wason, president, Cleveland, Painsville & Eastern Railroad Company. John Ehrhardt, assistant secretary; Albert E. Duty, assistant secretary, and C. B. Easty, master mechanic, Cleveland City Railway Company. R. M. Douglass, general superintendent; F. S. Barton, assistant secretary and treasurer; W. G. McDole, auditor; Charles W. Wason, purchasing agent; B. Maher, assistant secretary, and L. M. Wolf, assistant purchasing agent, Cleveland Electric Railway Company.

Cincinnati, Ohio—G. B. Kerper, general manager; Henry Burkhold, private secretary, Cincinnati Street Railway Company.

Columbus, Ohio—P. V. Burington, auditor; J. W. McCord, Columbus Street Railway Company.

Council Bluffs, Ia.—W. S. Dimmock, general superintendent, Omaha & Council Bluffs Railway & Bridge Company.

Davenport, Ia.—F. C. Denkmann, vice-president; James F. Lardner, secretary; John F. Huntoon, general superintendent, and John D. Fish, electrician, Tri City Railway Company.

Dayton, Ohio—George B. Kerper, general manager, and Nelson Routzahn, superintendent, People's Railway Company.

Des Moines, Ia.—George B. Hippee, general manager, and J. S. Goodrell, chief engineer, Des Moines City Railway Company.

Duluth, Minn.—Herbert Warren, general manager, Duluth Street Railway Company.

Detroit, Mich.—S. Hendrie, manager; F. A. Baker, director, Detroit & Pontiac Street Railway Company.

Denver, Col.—C. K. Durbin, general superintendent, Denver City Tramway Company.

Evansville, Ind.—H. D. Moran, vice-president and general manager, Evansville Street Railway Company.

Elgin, Ill.—William Grote, president; James B. Lane, vice-president; Charles Wuestenfield, Elgin City, Carpenterville & Aurora Railway Company.

Findlay, Ohio—George B. Kerper, president; W. G. Nusbaum, engineer, and William Twining, electrician, Findlay Street Railway Company.

Gloucester, Mass.—E. C. Foster, president, Gloucester Street Railway Company.

Grand Rapids, Mich.—G. S. Johnson, president; Benjamin S. Hanchett, Jr., assistant secretary and treasurer, Consolidated Street Railway Company.

Galveston, Tex.—F. W. Fratt, superintendent and engineer, Galveston City Railroad Company.

Hartford, Conn.—E. S. Goodrich, president; Elmer M. White, cashier, Hartford Street Railway Company.

Harrisburg, Pa.—F. B. Musser, superintendent; Mason D. Pratt, engineer, Harrisburg Traction Company.

Hazleton, Pa.—E. S. Doud, secretary and treasurer; C. A. B. Houck, electrician, Lehigh Traction Company.

Houston, Tex.—H. F. McGregor, vice-president and general manager; R. M. Johnston, stockholder, Houston Electric Street Railway Company.

Hamilton, Ont.—C. K. Green, director; J. B. Griffith, manager, Hamilton Street Railway Company.

Hamilton, Ohio—Will Christy, president; F. J. J. Sloat, general manager; C. E. Hooven, secretary; J. C. Hooven, director, Cincinnati & Hamilton Electric Street Railway Company.

Indianapolis, Ind.—Charles Remelius, superintendent motive power; John Grant, assistant general manager; H. B. Bales, auditor, Indianapolis Street Railway Company.

Jersey City, N. J.—E. D. Hibbs, auditor, North Jersey Street Railway Company.

Johnstown, Pa.—H. C. Evans, director, Johnstown Passenger Railway Company.

Joliet, Ill.—F. E. Fisher, superintendent; W. H. Huen, auditor; W. J. Kelsch, electrician, Joliet Street Railroad Company.

Kansas City, Mo.—Walton H. Holmes, president; J. A. Harder, auditor; William A. Sallerton, superintendent; Edward Butts, chief engineer; T. Blake, engineer; W. H. Miller, George Wing, Metropolitan Street Railway Company.

Lynn, Mass.—E. C. Foster, vice-president and general manager, Lynn & Boston Railroad Company.

London, Ont.—C. E. A. Carr, general manager and secretary; J. F. Hill, auditor, London Street Railway Company.

Lexington, Ky.—E. C. Hathaway, general manager; E. A. Longuere, engineer, Lexington Railway Company.

Louisville, Ky.—T. J. Minary, president; S. G. Boyle, secretary; J. T. Funk, C. L. Christopher, superintendents track construction, Louisville Railway Company.

Merrimac, Mass.—James T. Wattles, Haverhill & Amesbury Street Railway Company.

Meriden, Conn.—N. H. Heft, president; William Tooker, engineer, Meriden Electric Railroad Company.

Memphis, Tenn.—F. G. Jones, vice-president and general manager; C. H. Ruddock, director; W. B. Mallory, director, Memphis Street Railway Company.

Milwaukee, Wis.—John I. Beggs, general manager; H. C. Mackay, auditor; F. Sargent, consulting engineer; T. E. Mitten, general superintendent railway department; Chester P. Wilson, engineer; George Kemmerlein, superintendent of transportation;

W. H. Greenslade, assistant superintendent of transportation; S. G. Mitten, superintendent of overhead construction; E. Wolds, superintendent of maintenance of rolling stock; C. H. Lemon, surgeon; T. Simmons, roadmaster; T. G. Hoffman, clerk, Milwaukee Electric Railway & Light Company.

Minneapolis, Minn.—J. F. Calderwood, auditor; P. S. Mackay, assistant auditor; F. D. Valentine, chief clerk; A. M. Baldwin, purchasing agent, Twin City Rapid Transit Railway Company.

Mexico, Mex.—Arthur S. Partridge, engineer, Compania de Ferro-Carriles del Distrito Federal de Mexico.

Montreal, Can.—Duncan McDonald, superintendent; H. A. Brown, electrician; W. A. Ross, comptroller, Montreal Street Railway Company.

New Bedford, Mass.—E. E. Potter, general superintendent; Elton S. Wilde, treasurer, Union Street Railway Company.

New York, N. Y.—H. H. Vreeland, president; A. C. Tully, purchasing agent; J. F. Kane, chief of construction, Metropolitan Street Railway Company.

New Brunswick, N. J.—E. H. Radel, secretary and treasurer; John Blair MacAfee, Brunswick Traction Company.

Nashville, Tenn.—E. G. Conette, general manager; N. P. Yeatman, secretary and treasurer, Nashville Street Railway Company.

New Orleans, La.—J. K. Newman, president; George H. Davis, manager; A. O. Kittredge, consulting accountant, New Orleans & Carrollton Railroad Company. A. H. Ford, secretary and treasurer; C. D. Wyman, general manager; T. H. Tutwiler, engineer, New Orleans City Railroad Company.

Omaha, Neb.—W. A. Smith, general manager; D. H. Goodrich, secretary, Omaha Street Railway Company.

Oakland, Cal.—E. A. Heron, president, Oakland Transit Company.

Portland, Me.—William R. Wood, president; William A. Wheeler, director; A. Whitney, director, Portland Railroad Company. Merle R. Griffith, electrician; F. C. Boyd, director, Portland & Yarmouth Electric Railway Company.

Port Chester, N. Y.—N. H. Heft, engineer; Marion Swing, assistant engineer, Port Chester Street Railway Company.

Philadelphia, Pa.—Henry C. Moore, vice-president; J. J. Mahoney, electrical engineer, Roxborough, Chestnut Hill & Norristown Railway Company.

Pittsburgh, Pa.—S. E. Moore, auditor; C. S. Mitchell, assistant auditor, United Traction Company.

Port Huron, Mich.—A Dixon, president; H. A. Dixon, superintendent, City Electric Railway Company.

Peoria, Ill.—L. E. Myers, secretary and general manager, Peoria & Pekin Terminal Railway Company.

Quincy, Mass.—John R. Graham, president and general manager, Quincy & Boston Railway Company.

Quincy, Ill.—H. E. Chubbuck, electrical engineer; L. A. Scovil, superintendent, Quincy Horse Railway & Carrying Company.

Pasadena, Cal.—W. H. Smith, Los Angeles & Pasadena Electric Railway Company.

Pueblo, Col.—John F. Vail, general manager, Pueblo Traction & Electric Company.

Rockland, Me.—George E. Macomber, president; Thomas Hawken, superintendent; William N. Todd, Rockland, Thomaston & Camden Street Railway Company.

Rochester, N. Y.—J. H. Stedman, manager of transfers, Rochester Railway Company.

Reading, Pa.—Samuel E. Rigg, superintendent; Henry C. Moore, director, United Traction Company.

Richmond, Va.—Berkeley Williams, purchasing agent, Richmond Traction Company.

Syracuse, N. Y.—Ira A. MacCormack, vice-president and managing director, Syracuse Rapid Transit Railway Company.

Scranton, Pa.—C. E. Flynn, general manager, Carbondale Traction Company.

Springfield, Ill.—C. K. Minary, manager; T. H. Minary, electrician, Springfield Consolidated Railway Company.

Springfield, Ohio—Fred. Colburn, president; S. L. Nelson, general manager; L. O. Williams, superintendent, Springfield Railway Company.

St. Louis, Mo.—F. S. Drake, master mechanic, Cass Avenue & Fair Grounds Railway Company; J. J. Coleman, general manager, Citizens, Missouri, Southern, St. Louis and Union Depot Railroad Companies. J. J. Coleman, general manager; Samuel Barnes, electrical engineer, Lindell Railway Company. T. M. Jenkins, general manager; G. J. Smith, master mechanic, St. Louis & Suburban Railway Company.

Saginaw, Mich.—L. M. Richardson, superintendent, Saginaw Valley Traction Company.

St. Joseph, Mich.—W. Worth Bean, president; H. C. Mason, superintendent; W. Worth Bean, Jr., assistant superintendent, St. Joseph & Benton Harbor Electric Railway & Light Company.

Salt Lake City, Utah—W. P. Read, general superintendent; O. P. Arnold, assistant superintendent, Salt Lake City Railroad Company.

Sioux City, Ia.—Fred. H. Fitch, general manager; C. M. Feist, master mechanic; Louis W. Price, cashier, Sioux City Traction Company.

Schenectady, N. Y.—S. D. Greene, vice-president; W. Gibson Carey, Schenectady Street Railway Company.

St. Joseph, Mo.—J. B. Shirley, auditor; J. H. Van Brunt, superintendent, St. Joseph Railway, Light, Heat & Power Company.

Taunton, Mass.—John McClannel, assistant superintendent of transportation, Taunton Street Railway Company.

Trenton, N. J.—Henry C. Moore, president; Charles Y. Flanders, director, Trenton Street Railway Company.

Toledo, Ohio—Albion E. Lang, president; Thomas H. McLean, vice-president and general manager; Charles L. Wright, auditor; E. J. Bechtel, superintendent construction; G. Munz, superintendent shops, Toledo Traction Company. W. B. Brockway, secretary and auditor; C. A. Denman, general manager, Toledo, Bowling Green & Fremont Railway Company.

Topeka, Kan.—Albert M. Patten, superintendent, Topeka Railway Company.

Toronto, Can.—E. H. Keating, manager; Ewan Mackenzie, assistant superintendent; P. McCullough, electrician, Toronto Railway Company.

Venice, Ill.—Fred. E. Allen, president; E. J. Spencer, secretary, Venice, Madison & Granite City Railway Company.

Wilkesbarre, Pa.—Thomas A. Wright, general superintendent; James Fagan, electrical engineer, Wilkesbarre & Wyoming Valley Traction Company.

Wilmington, Del.—Henry C. Moore, vice-president; W. E. Boughton, director, Wilmington City Railway Company.

Wheeling, W. Va.—W. A. Shirley, secretary and treasurer, Wheeling Railway Company.

Webb City, Mo.—E. J. Pratt, superintendent motive power; C. E. Baker, superintendent transportation, South-West Missouri Electric Railway Company.

York, Pa.—W. H. Lanius, president, York Street Railway Company.

Youngstown, Ohio—A. A. Anderson, general manager and treasurer; Harry Dixon, assistant treasurer; James F. Uhl, Mahoning Valley Railway Company.

Others in Attendance

Neff, Stewart L., superintendent, Union Loop, Chicago.

Waterman, John H., director, Little Rock Traction & Electric Company, Little Rock, Ark.

McDonald, F., Waterloo & Cedar Rapids Traction Company, Waterloo, Ia.

Crankshaw, J. B., electrical engineer and manager, Cincinnati, Lawrenceburg & Aurora Street Railway Company, Cincinnati, Ohio.

Johnson, J. M., electrician and master mechanic, LaCrosse City Railway, LaCrosse, Wis.

Valier, Porter, superintendent, LaCrosse City Railway Company.

Cameron, J. L., president, Salt Lake City Rapid Transit Company.

Flint, J. A., secretary, treasurer and manager, San Diego Electric Railway Company, San Diego, Cal.

Asire, M. E., secretary and treasurer M. C. & P. I. Railway Company, Marquette, Mich.

DeCoursey, H., train master, Leavenworth Electric Railroad Company, Leavenworth, Kan.

Coomb, E. E., manager, Leavenworth Electric Railroad Company, Leavenworth, Kan.

Nary, W. T., superintendent, Hoosac Valley Street Railway Company, North Adams, Mass.

Torbert, H. G., assistant manager, Suburban Street Railway Company, Dubuque, Ia.

Blackwood, D. P., passenger agent, Washington, Arlington & Falls Church Railway Company, Washington, D. C.

Gunn, E. B., superintendent, LaFayette Street Railway Company, LaFayette, Ind.

Diserens, F. L., superintendent, Cedar Rapids & M. City Railway, Cedar Rapids, Ia.

Daniell, Edward, secretary, treasurer and superintendent, Menominee Electric Light, Railway & Power Company, Menominee, Mich.

Doyle, J. L., master mechanic, Metropolitan Elevated Railroad Company, Chicago.

Budd, B. I., purchasing agent, Metropolitan West Side Elevated Railway Company, Chicago.

McCoy, Frank, superintendent, Monongahela Street Railway Company, Pittsburgh, Pa.

Ellis, T. M., general manager, Rockford Railway, Light & Power Company, Rockford, Ill.
Williams, William H., electrician, St. Louis & East St. Louis Railway Company, St. Louis, Mo.
Cummins, W., superintendent, Indiana Railway Company, South Bend, Ind.
Halliday, E. W., president, Cairo Electric Railway Company, Cairo, Ill.
Ginn, F. E., superintendent, Lancaster Traction Company, Lancaster, Ohio.
Hertig, C. M., president, Benton Power & Traction Company, St. Cloud, Minn.
Ralph, I. D. H., president and general manager, Owosso & Corunna Electric Company, Owosso, Mich.
Misaki, Siezo, chief engineer and superintendent, Hauskin Electric Railway Company, Kobe, Japan.
McFarland, J. W., superintendent, Chattanooga Electric Railway Company, Chattanooga, Tenn.
Baylies, R. N., president, Rockford Railway, Light & Power Company, Chicago.
Irwin, William G., president, Indianapolis, Greenwood & Franklin Railway, Indianapolis, Ind.
Wright, J. E., secretary, Detroit & Northwestern Railway, Detroit, Mich.
Boyd, F. C., director, Ohio Central Traction Company, Galion, Ohio.
Anthony, William, Ohio Central Traction Company, Galion, Ohio.
Downs, Edwin E., vice-president and general manager, Citizens' Traction Company, Oshkosh, Wis.
Cass, L. S., president and general manager, Waterloo & Cedar Falls Rapid Transit Company, Waterloo, Ia.
Thompson, Fred W., superintendent, Muskegon Street Railway Company, Muskegon, Mich.
Detwiler, G. K., secretary, Toledo & Maumee Valley Railway Company, Toledo, Ohio.
Hart, George A., president and general manager, Manistee, F. C. & E. Railway, Manistee, Mich.
Winters, Valentine, president, Dayton & Western Traction Company, Dayton, Ohio.
Miller, E. F., supervisor of motormen, South Side Elevated Railroad Company, Chicago.
Clegg, Harry Pease, secretary and general manager, Oakwood Street Railway Company, Dayton, Ohio.
Gustafson, C., superintendent, Oakland, San Leandro & Hayward Electric Railway, Consolidated, Elmhurst, Cal.
Jewett, Edwin, chief engineer, South Chicago City Railway, Chicago.
Saemann, Franklin I., treasurer, Sheboygan Light, Power & Railway Company, Sheboygan, Wis.
Green, C. K., manager, Hamilton Radial Electric Railway, Hamilton, Ont.
Colvin, J., superintendent, Washington, Alexandria & Mt Vernon Railway Company, Washington, D. C.
Carney, N. L., president, Electric Street Railway, Clarksville, Tenn.
Semenza, Guido, Milan Edison Company, Milan, Italy. (Italian representative Street Railway Journal).
Zimmerman, Frank M., superintendent, Collins Park & Belt Railway, Atlanta, Ga.
Grover, T. F., vice-president and general manager, Fond du Lac Street Railway & Light Company, Fond du Lac, Wis.
Wilkins, James H., chief electrician and master mechanic, St. Louis & Belleville Railroad Company, Belleville, Ill.
Frederick, C. R., engineering department, Northwestern Elevated, Chicago, Ill.
Seacord, Judd, superintendent, Galesburg Electric Motor & Power Company, Galesburg, Ill.
Brown, William J., general manager, Home Electric Company, Dubuque, Ia.
Parsel, Jr., J. S., superintendent, Fairfield Traction Company, Lancaster, Ohio.
Kent, James, superintendent, Washington Electric Company, Washington, Pa.
Paul, G. J. A., superintendent, Henderson Street Railway Company, Henderson, Ky.
Clark, Edward C., assistant secretary, Cedar Rapids & Marion City Railway, Cedar Rapids, Ia.
Holbrook, Royal H., chief engineer, Cedar Rapids & Marion City Railway, Cedar Rapids, Ia.
Carpenter, Reid, treasurer, Citizens' Electric Railway, Mansfield, Ohio.
Greene, E. M., superintendent, Signal Mountain Railway Company, Chattanooga, Tenn.
Payne, H. B., electrician, Ottawa Railway, Light & Power Company, Ottawa, Ill.
Miller, Irving W., superintendent, Olean Street Railway Company, Olean, N. Y.
Given, Frank S., assistant general manager, Pennsylvania Traction Company, Lancaster, Pa.
Vieley, Elmer, master mechanic, Cedar Rapids & Marion City Railway, Cedar Rapids, Ia.
Cummins, M., superintendent, Indiana Railway Company, Elkhart, Ind.
Perdue, Whittier, superintendent of construction, Chicago Electric Traction Company, Chicago.
Hazelrigg, S. F., general manager, Atlantic Coast Elevated Railroad Company, Asbury Park, N. J.
Allen, Andrew J., general foreman of motive power, South Side Elevated Railroad, Chicago.
Burke, J. P., vice-president and manager, San Jose & Santa Clara Railroad Company, San Jose, Cal.
Cobb, C. H., vice-president and general manager, Kankakee Electric Railway Company, Kankakee, Ill.
Dyer, Jr., R. A., superintendent, Auburn City Railway Company, Auburn, N. Y.
Weed, H. I., attorney, Citizens' Traction Company, Oshkosh, Wis.
Gillingham, Jr., W. J., signal engineer, Illinois Central Railroad Company, Chicago.
Berry, Kav., electrician, Henderson Street Railway Company, Henderson, Ky.
Reed, William L., secretary, Omaha, Council Bluffs & Suburban Railway Company, Council Bluffs, Ia.
Townsend, George, president, Omaha, Council Bluffs & Suburban Railway Company, Council Bluffs.
Poor, F. A., foreman signals, Illinois Central Railroad Company, Chicago.
Barvion, A. M., general manager, Home Electric Light & Power Company, Elkhart, Ind.
Hart, H. D., director, St. Charles Street Railroad Company, New Orleans, La.
Kilmer, F. D., Santa Fe Railway Company, Oak Park, Ill.
Hourigan, John, auditor, Albany Railway Company, Albany, N. Y.
Harry, C. L., manager, Kokomo City Street Railway Company, Kokomo, Ind.
Evarts, Charles O., treasurer, Kansas City & Leavenworth Railway Company, Leavenworth, Kan.
Kimberley, D. H., president, Kansas City & Leavenworth Railway Company, Leavenworth, Kan.
Henry, F. R., secretary and treasurer, Missouri Railroad Company, St. Louis, Mo.

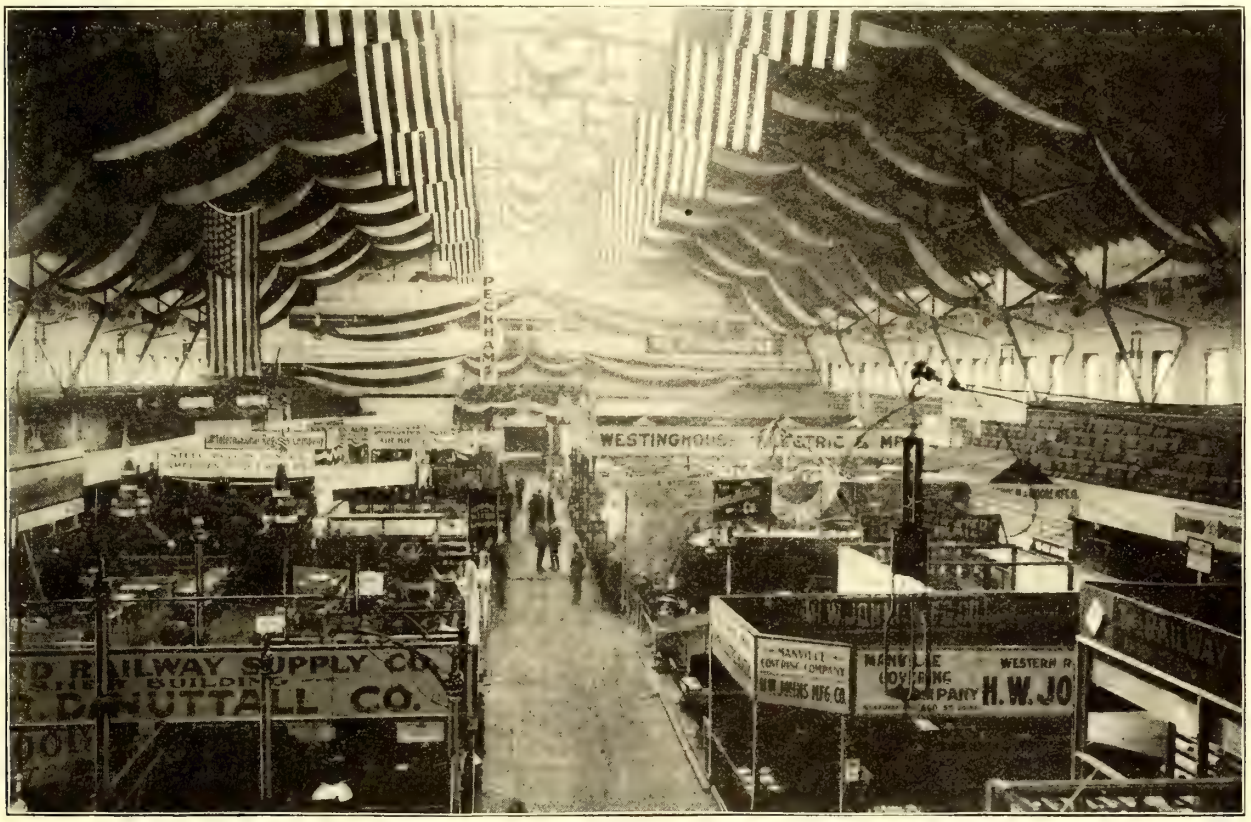
EXHIBITS AT THE CONVENTION



THE BUDA FOUNDRY & MANUFACTURING COMPANY, of Chicago, showed some of the well known Paulus drills and a special rapid running small drill for putting in rail bonds. The company's foreign business, in the hands of Laing, Wharton & Down, of London, has increased to large proportions, one foreign city alone having ordered within the past few months 500 drills. The exhibit was in charge of John McKinnon.

THE GREEN ENGINEERING COMPANY, of Chicago, was represented by P. Albert Poppenhusen. This company has recently secured several of the largest orders ever placed for traveling grates. The company represents the Edgemoor Iron Company, Goubert Manufacturing Company, Monarch Manufacturing Company and Broomell, Schmidt & Company.

THE CHISHOLM & MOORE MANUFACTURING COMPANY, of Cleveland, was represented by Col. W. E. Ludlow, manager of its American rail joint department, who has for the last twenty years been studying the needs of the track department of railways. The company states that with the completion of its malleable plant it is prepared to make about 10,000 joints per month, and therefore makes the following proposition to those who will want to commence laying track early next spring. It will close contracts for what joints will be wanted in the spring, and give the benefit of prices in force at time contract is made, purchaser to pay for same within thirty days of date of shipment, and shipments to be made at such time as purchaser may designate, but not later than May 1, 1900. A section of rail, 3 ft. in length, showing drilling, must be furnished within thirty days of date of contract. The company will at once make a joint and fit to rail and return for acceptance, and will guarantee that all others shall be same as sample. The joints on exhibition were samples of those furnished to different cities as follows: Chester, Pa.; Cincinnati, three sizes; Wilmington, Del.; Louisville, Ky.; Mobile, Kansas City and Detroit. There was also shown one of the latest types of joint on an 80-lb. T-rail, which, in order to test the material, had been driven on with forty blows of a 20-lb. sledge. Among the company's latest orders are 10,000 joints for the Chicago Union Traction Company, and 7500 for the Calumet Electric Railway in Chicago. The company is open for new ideas in track material and is prepared to manufacture same in its immense new plant. One of the newest things it has brought out is a rail-bracing tie-plate, which is proving popular. It also exhibited samples from its twenty-one sizes of differential hoists, in capacities from ½-ton to 20 tons and operated by compressed air, electricity, steam or hand power. Its souvenir was a track gage of Pennsylvania Railroad standard, which will be sent to anyone requesting same. The gage shows that with Fahrenheit thermometer readings of 80 degs. or over, the rail ends should butt tightly together; from 60 degs. to 80 degs., they should be 1/16 in. apart; from 40 degs. to 60 degs., ⅛ in. apart; from 20 degs. to 40 degs., 3/16 in. apart, and from zero to 20 degs., ¼ in. apart.

A. L. IDE & SONS, of Springfield, Ill., were represented by their genial Chicago agent, Enos Bookwalter.

THE PAIGE IRON WORKS, of Chicago, exhibited blue prints and photographs of their special track work, crossings, curves, switches, stands, etc. The company's output is distributed all over the city of Chicago and can be found on the Calumet, the Chicago City, North & West Chicago, South Chicago City, and the Chicago Electric Traction Company's lines. The company's shops are running to their fullest capacity, supplying orders not only for the roads mentioned but for others in almost every State in the Union. The exhibit was in charge of E. S. Nethercut, chief engineer. Other representatives present were J. M. Spackman, secretary; George Lowe, superintendent; T. H. Lovejoy, assistant superintendent.

GENERAL VIEW OF EXHIBITION HALL

C. F. ORR & COMPANY, of Chicago, exhibited some handsome uniforms for street railway conductors and motormen. C. F. Orr, owner of the business, reports that his trade with street railway companies all over the country is increasing at a rapid rate. He has recently booked orders from several Southern roads.

THE ATLAS RAILWAY SUPPLY COMPANY, of Chicago, had one of the handsomest booths at the exposition. A dainty maid served boullion and crackers and each lady visitor was presented an American beauty rose. Each gentleman caller went away with a carnation in his coat lapel. The company exhibited the Atlas rail joint, of which 275,000 are in use; also, "Cartime Surfacer," which is not a paint in the ordinary sense of the word, as it is a combination of materials which is not affected by ammonia,

carbonic, sulphurous or other gases, salt water, smoke or acids. It will not crack, peel off nor blister, and will last three times as long as white lead or mineral paint. It expands and contracts with the heat and cold on iron or tin roofs and will not scale off or become loose. These compositions have been in use on many of the leading railroads for the past nine years.

K. M'LENNAN & COMPANY, of Chicago, sole manufacturers of Gale's commutator compound, were represented by W. J. Isaacs, the manager of the company. This company's exhibit consisted of Gale's commutator compound. One of the features of the booth was a large bulletin board, on which were attached several hundred extracts from testimonials, and at the side of the board two original testimonials were displayed. Judging from the number of samples of compound which this company gave out at its exhibit, its compound is a necessity to the users of dynamos and motors. A neat souvenir was distributed in the way of a "Mauser" cartridge knife, which was much sought.

THE MANVILLE COVERING COMPANY, of Chicago, Western representatives of the H. W. Johns Manufacturing Company, had an attractive exhibit, showing a very complete line of molded mica overhead insulation, electric car heaters, vulcabeston

HE ADQUARTERS OF THE STREET RAILWAY JOURNAL

parts for street car motors and controllers. A special feature of this exhibit was the "Noark" fuse, it does not arc, but is an ideal protective against overload or short circuit, and a safe, accurate and correct motor protection. H. A. Reeves, who is manager of the electrical department of the Manville Covering Company, has had charge of the same department of the H. W. Johns Manufacturing Company since 1891, during which time he has succeeded in handling some large contracts for the latter concern. Six representatives of the H. W. Johns Manufacturing Company were also in attendance.

THE DIXON CRUCIBLE COMPANY, of Jersey City, N. J., was represented by Sam Mayer and Dudley Johnson, the company's Chicago representatives, and A. L. Harris, E. A. St. John and William Allen. The souvenirs of this company were large Uncle Sam pencils—also a thick pencil which, when once placed in the buttonhole, could not be detached without a deal of study, also souvenirs of plumbago medals made of the same graphite as used in Dixon's world renowned pencils. The Dixon booth soon became the headquarters of many of the old-timers, who thought they knew a good thing when they saw it. Large orders were booked for Dixon's graphited wood grease for use on electric railway car gears, and which was claimed to be something new and something better than ever before offered railway companies. Its advantages were said to be that it prevents noisy gears, keeps the gears and bearings constantly lubricated, prevents all drippings from gear cases and lasts longer and is more economical than any other lubricant.

THE LESCHEN-MACOMBER-WHYTE COMPANY, of Chicago, was represented by F. B. Macomber, George S. Whyte and E. E. Robirds. The exhibit consisted of galvanized steel strand, galvanized curtain cord, galvanized telephone wire, rubber insulated wires and cables, weather-proof feeder wires, magnet wire, "Century" tape, "Beacon" bearing metal, overhead line material, and the Standard head light. A very neat paper cutter was distributed as a souvenir. While the principal business of the Leschen-Macomber-Whyte Company is wire rope, its trade in the street railway direction is rapidly increasing and is now reaching large proportions.

THE MEAKER MANUFACTURING COMPANY, of North Chicago, was represented at the Chicago convention by J. W. and G. L. Meaker. The exhibit consisted of the Meaker registers, every detail of which is so thoroughly familiar to street railway men that any attempt at description would be superfluous. The company's handsome new catalogue which was given out, explained the register to the few who were so far behind the times as to be ignorant concerning it.

THE CHAPMAN VALVE MANUFACTURING COMPANY, of Indian Orchard, Mass., had a booth in charge of E. W. Buss, Western manager, where was displayed a line of valves for steam, water, gas, oil and ammonia, ranging in pressure from 50 lbs. to 250 lbs.

J. R. M'CARDELL & COMPANY, of Trenton, N. J., showed their tower wagon, of which over 400 are in use, although the company's first patents were issued in 1895. This wagon is in service in every country where there are electric railways, and over forty have been shipped to Europe during the present year. The wagon can be operated easily by one man, and can be changed to any position in one-quarter of the time required by collapsible wagons. It embodies certain principles of construction that render it impossible that it ever should become loose-jointed or dangerous. The wagon is built on honor with an eye solely to its utility and durability.

THE CUTTER ELECTRICAL & MANUFACTURING COMPANY, New York, in connection with McGill, Pomeroy & Company, the company's Western agents, showed its new type of circuit breaker. Old standard types were not exhibited since they are too well known to street railway men to need it. V. C. Gilpin, in charge, stated that he will be pleased to set up this new type of circuit breaker anywhere and without charge until thoroughly tested. It has been designed to meet the severest conditions incident upon the transmission of power, and combines with ease of operation and high current carrying efficiency, promptness and certainty of action. The main switch contact is made by a "laminated wedge," involving a new feature in switch construction and producing a switch which combines high carrying capacity with small size. During the opening of the main switch it is amply protected by a shunt switch, whose circuit is not only of low resistance, but non-inductive as well, thus altogether obviating the possibility of arcing at the main contacts. The final break is made on carbon.

THE MURPHY FURNACE COMPANY, Detroit, Mich., had its interests cared for by W. G. Amos, Chicago agent, who is well known to Western steam users.

EUGENE MUNSELL & COMPANY and THE MICA INSULATOR COMPANY, of New York, Chicago and London, occupied space No. 11, 200 sq. ft. The booth was very tastefully gotten up, dark rich blue material paneled in gilt, being used as the background, giving a very rich effect. The companies' space, being fitted up with easy chairs and a handsome rug, somewhat resembled a richly furnished parlor. The Mica Insulator Company's exhibit consisted of "micanite" plate, flexible plate, cloth, paper, M. I. C. compound, "empire" cloth and paper, "micanite" tubes and troughs, and various forms of insulation, of which this company makes a specialty. Eugene Munsell & Company's exhibit consisted of "mica" in the sheet, and a variety of sizes. Both the India and amber qualities were shown, also mica as it comes from the mines, and mica segments. Directly over the desk, suspended from the sign, was a large rare specimen of India mica, measuring 14 ins. x 36 ins., probably one of the largest sheets ever mined. This is such a rare specimen that there are probably less than 3 lbs. or 4 lbs. of mica of these dimensions in

the United States. The souvenir distributed was a very neat card-case, and it was highly appreciated by the delegates in attendance. The exhibit was in charge of Charles E. Coleman, Western manager, assisted by Howard M. Frantz.

WILLIAM WHARTON, JR., & COMPANY, Inc., of Philadelphia, Pa., exhibited their standard manganese steel special track work, among which was the Nichols protected heel tongue The Wharton unbroken main line switch, although well known, was examined by many. There were shown several novelties in track work, among which was the Nichols protected heel tongue switch, which prevents entirely the throwing of the tongue between wheels and the kicking of the tongue. A steam and street railway crossing, in which the steam rail was made entirely of

EXHIBIT OF THE IRONSIDES CO.

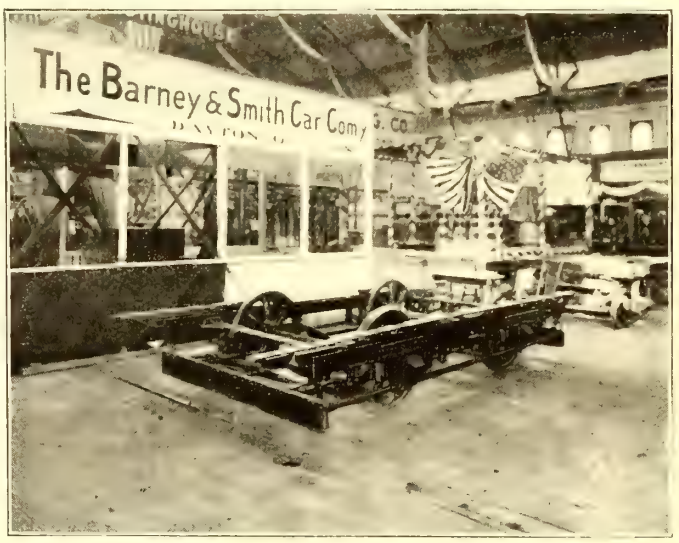


EXHIBIT OF THE BARNEY & SMITH CAR CO.

EXHIBIT OF THE INTERNATIONAL REGISTER CO.

EXHIBIT OF HEYWOOD BROS. & WAKEFIELD CO.

manganese steel, combining the running rail, guard rail, filler and third-rail, all in one piece, proved of interest to those who had had trouble with other steam railroad crossings in their tracks. A steam and street railroad crossing frog with manganese steel center for paved streets was shown and highly commended by track engineers. An example of its particular adaptation was shown by a large plan of a very intricate track layout in front of the new South Boston station in the city of Boston, in which a great mass of special work is crossed by a steam track. This layout, by the way, will be one of the, if not the most, important layout in Boston. Samples of T-rail, frogs and switches, cast entirely out of manganese steel, showed what strides had been made in handling this remarkable metal, which combines extreme hardness with great toughness. A double spring frog, long radius switch, complicated curving pieces and photographs of work made by the Wharton Company were further objects of the exhibit. The representatives present were F. P. Howe, first vice-president; Victor Angerer, second vice-president, Philadelphia; A. S. Partridge, St. Louis representative, and J. C. Robinson, of Harrington, Robinson & Company, agents in Boston.

THE AMERICAN MASON SAFETY TREAD COMPANY, of Boston, was represented by Herman Pfeffer, its Chicago agent, and Fletcher Randall, Cleveland agent, who showed the Mason unwearable non-slipping treads for street cars. These treads are adapted for both open and closed cars. They may also be applied to wood, iron, marble or granite stairs, to hydrant and manhole covers, coal hole covers and for similar uses. The tread is now in use on the Cleveland Electric Railway, the steps of the Boston Subway, the Brooklyn Bridge, the Chicago Elevated Railway and in many other important places.

ADAM COOK'S SONS, of New York, made an exhibit through their Western agents, Winne & Kellogg, of Chicago. The display included a variety of lubricating oils of the "Albany" brand, and greases, and compression and spindle grease cups of various sizes and for various purposes.

OWING to large increase of its business, the Springfield Manufacturing Company, of Bridgeport, Conn., manufacturer of car wheel and tool grinders, was unable to prepare for exhibit either a car wheel grinder or tool grinder. This company manufactures, in addition to the car wheel grinder exhibited at Buffalo and Boston, a machine using an 18 ins. x 1½ ins. emery wheel, also two different styles of single end grinders specially adapted for the smaller systems. The company was represented by its general manager, George W. Jackman.

THE FALK COMPANY, of Milwaukee, Wis., showed numerous large and very handsome photographs, some of which represented track, overhead and power-house construction of the Oshkosh & Neenah (Wis.) road, owned by the Citizens Traction Company, of Oshkosh, Wis. All of this work was built by the Falk Company under the superintendence of W. F. Carr, chief West Chicago Street Railway. Other pictures represented the engineer of the Falk Company, and recently chief engineer of the

construction of the Metropolitan Street Railway at Kansas City, Mo., illustrating particularly track construction and showing track laid in concrete beam without ties, which was described by Mr. Butts, chief engineer of the Metropolitan Street Railway Company, of Kansas City, in his paper read before the association. Other pictures showed some of the novel features of cast welding on the Third Avenue line, New York City, where the cars are run continuously, and special clamps were devised in this case so that the work could be carried on without interruption to traffic. Another of the series of large pictures was of gears and pinions manufactured by the Falk Company. This picture showed one of their large shipments to Cairo Tramways Company, Cairo, Egypt, which practically illustrated the wide extent of the business of the Falk Company. The company was represented by Gen. Otto H. Falk, Herman W. Falk, President, E. A. Wurster, Secretary and Treasurer, Clement C. Smith, Vice-President, Charles L. Jones, Assistant Secretary, Jacob Wendell and R. L. McDuffie, Eastern representatives of the company.

THE DEARBORN DRUG & CHEMICAL WORKS, with general offices and laboratories in Chicago, had a very elaborate booth decorated in red and green, with trimmings of red and green, and an abundance of flags. This company of chemists, organized some fourteen years ago, has built up a very extensive business in the treatment of boiler feed waters as per analysis, going into the subject most thoroughly and scientifically. In fact, it has developed the boiler compound business so that it is recognized to-day by the most practical engineers as a subject on which considerable economy can be obtained in the operation of the steam plant. All such analyses of waters are made free of charge and reported to the steam user with information as to the treatment required to prevent scale formation, and to overcome internal corrosive action, pitting, etc. These preparations are blended and prepared to meet the requirements of each case. These methods cannot help but appeal to the operator. These people are also in the refining and lubricating business, and their laboratory equipment for the refining and proper blending of lubricating oils, and the retesting of same, is probably the most thorough of any in existence. In the marketing of oils, this company, in the first place, gets the proper oil for the conditions of the steam plant, the first requisite being the highest quality and afterwards the price per gallon. Many of the largest steam plants in the United States are buying their oils of the Dearborn Company through its laboratory inspection, and the saving made in quantity required to give thorough lubrication has been something remarkable. When the proper oils are once introduced, every shipment is absolutely uniform on account of the double check testing system they employ. The company exhibited a very complete line of lubricating oils and greases, that are used especially by the street railway companies now running high pressure plants. Also to be seen in this booth were a great many interesting samples of scale formation, caused by different waters, and many samples of pipe, boiler tubes and braces, showing the different effects of pitting, caused by many waters charged heavily with sodium and potassium salts. Other specimens were shown illustrating the effect of some of the "cure all" boiler compounds, which are usually made from caustic soda, and while they reduce some scale formation, the deleterious after effect on the steam plant (such as pitting and corrosion) is a great deal worse than the apparent good effect obtained from removing some scale. This company has maintained for years that vegetable extracts only should be employed as feed water treatment; that they do the work perfectly in the boiler and act as a preservative to the entire system. The company gave as souvenirs a very handsome pocket spirit-level, and delighted the hearts of the ladies by presenting to each a bottle of very fine perfume, a product of its own laboratories. There were in attendance at the exhibit of this company Robert F. Carr, vice-president and general manager; Charles M. Eddy, secretary and treasurer; William B. McVicker, Eastern manager; T. J. McMaster, G. W. Spear and A. Ruffner, of the Chicago office. The company now has branch offices in Detroit, St. Louis, St. Paul, Denver, San Francisco and Los Angeles.

THE BARNEY & SMITH CAR COMPANY, of Dayton, Ohio, showed three trucks. Its maximum traction, double suburban and single truck. These trucks are too well known to the trade to require any description or explanation. A. M. Kittredge, superintendent; H. M. Esterbrook and H. Tesseyman were in attendance.

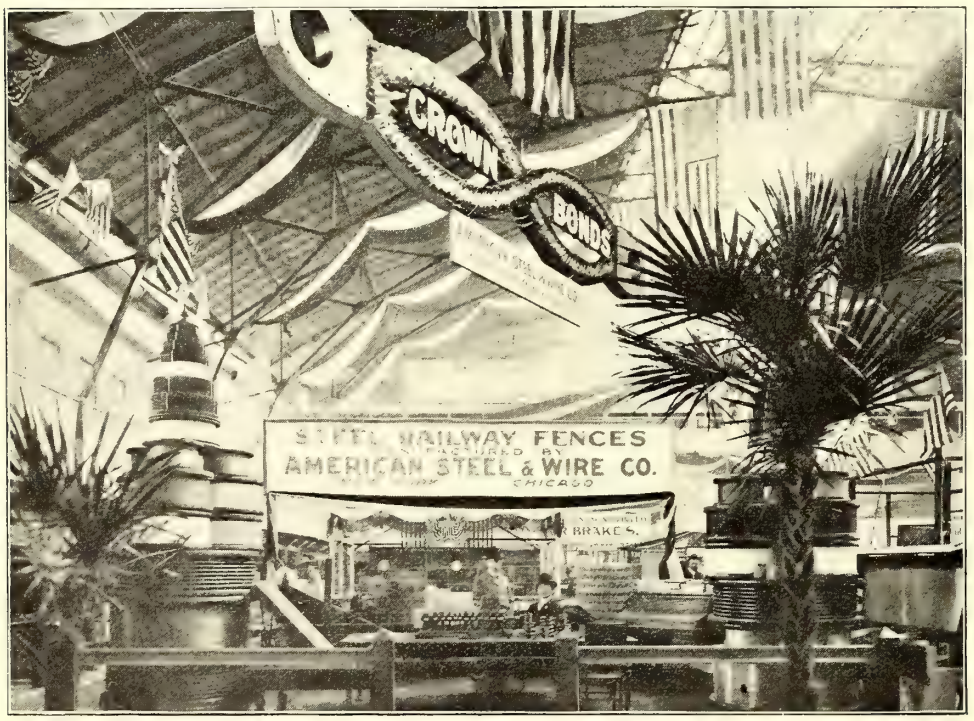

EXHIBIT OF AMERICAN STEEL & WIRE CO.

THE CENTRAL ELECTRIC COMPANY, of Chicago, had a very handsome booth decorated in yellow and black, and with a number of steel trolley poles spanning the doorway. M. M. Wood was in charge. There was exhibited a display board made up of overhead material, car fixtures, etc., elegantly polished. These were mostly of the well known Wood type, manufactured by the Central Union Brass Company. A brass cannon, a yoke of brass oxen, and a brass street car attracted no small attention. The company's souvenir was a neat brass paper cutter. The following gentlemen were also present: George A. McKinlock, president; Charles Brown, secretary, and C. W. Cobb.

THE GARTON-DANIELS ELECTRIC COMPANY, of Keokuk, Ia., was represented by J. V. E. Titus. Its booth contained a panel mounted with Garton station type arresters of different styles of finish, and connected with a 500-volt circuit. By the aid of a static machine the operation of the arresters was shown in a very satisfactory manner. They interrupt a short circuit so quickly that the ammeter shows little or no deflection. On a table was displayed a full line of pole, station and car arresters, as well as samples of 500-amp. and 800-amp. kicking coils, of which this company makes a specialty. Two samples were also shown of the Automotoneer, an invention of George W. Knox, electrical engineer of the Chicago City Railway Company. This device prevents too rapid starting of electric cars and attracted much attention. A more complete description will be given in these columns later.

THE EXHIBIT of the American Steel & Wire Company was a composite of all the different products of the company applicable to street railway interests. High above the booth swung a mammoth "Crown" rail bond, which was illuminated with more than a hundred incandescent bulbs, and at night was one of the most brilliant features of the exhibit. The words "crown bonds" were brought out with numerous electric lights. Crown bonds, indeed, in innumerable shapes and sizes, crown bonds, straight and twisted at every known curve and angle, were the "piece de resistance" of the American Steel & Wire Company's exhibit. These bonds, however, were supplemented on every side of the exhibit with devices calculated to interest every department of street railway maintenance and operation; trolley wires, round and odd-shaped, feeder wires and cables, steel armored cables, lead encased cables, submarine cables, magnet wires, every form of insulated wire, wire ropes, rheostat cables, car truck springs, etc. These again, were re-enforced by voluminous representation of

A GROUP OF PROMINENT EXHIBITORS

guy wires and span wires, both plain and twisted, also with huge model of the "high grade W. & M," double galvanized telephone and telegraph wires in "extra BB," "B B" and steel grates. Another feature was the exhibit of woven wire right-of-way fence. A panel of the company's celebrated "American" style of fencing was shown erected on the posts with stretcher attached and in operation. This company makes a specialty of railway fence building and has now contracts covering the erection of several thousand miles of right-of-way fencing in different parts of the country. It stands ready to demonstrate its ability to furnish all labor and material and turn over to the railway companies a better fence, and for less money, than the railway companies could secure in any other manner. Souvenirs in the form of solid leather memorandum and pocket-books were judiciously distributed. E. J. Pietzcker was in charge of the exhibit for the electrical department and George P. Rider was in charge of the fence exhibit.

H. P. CAMERON, Syracuse, N. Y., showed G. E.-800 commutators, and samples of his different styles for all kinds of street railway service. These commutators are made from the best drop forged Billings & Spencer segments, insulated with amber mica and turned to standard size. Perfect fit is guaranteed in every instance. He keeps a large stock made up and can ship any number promptly. Some large orders have recently been received.

THE MILLER KNOBLOCK COMPANY, of South Bend, Ind., was represented by its manager, A. W. Morrell. Its exhibit was a very fine line of assembled commutators for all standard

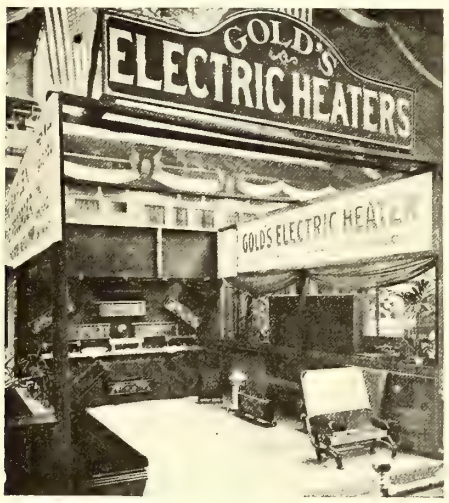

EXHIBIT OF GOLD'S ELECTRIC HEATERS

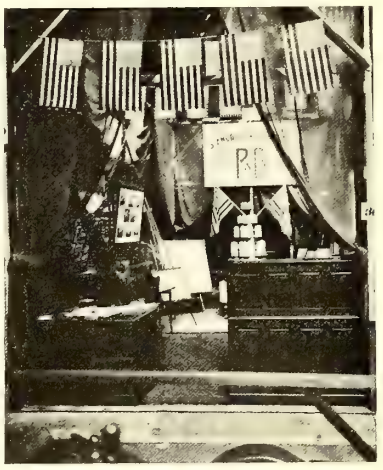

EXHIBIT OF THE STANDARD PAINT CO.

EXHIBIT OF THE SAFETY INSULATED WIRE & CABLE CO.

street railway motors. Its recently improved process for assembling commutators puts it well to the front on this class of work. A constantly increasing business has made it necessary to double the capacity of the company's shops. This exhibit elicited universal praise from street railway men. The company was also represented by A. M. Knoblock.

McGILL, POMEROY & COMPANY, of Chicago, were present in the persons of Mr. McGill, J. W. Porter and E. R. Mason. They showed samples of trolley poles, harps, wheels, rawhide pinions, and in connection with the Ohio Brass Company, a complete line of electric street railway supplies— "from the wire to the ties." In addition to their own line of supplies, they represent the following: The Ohio Brass Company, Mansfield, Ohio; the Forest City Electric Company, Cleveland, Ohio; the Cutter Company, Philadelphia, Pa.; the Orient Electric Company, Youngstown, Ohio.

THE CREAGHEAD ENGINEERING COMPANY, of Cincinnati, made its usual large exhibit of flexible brackets, overhead line material, iron and wood pole fittings, rail bonds, etc. One particularly attractive feature of this exhibit was an extra heavy double bracket for center pole construction, which was recently supplied for the rebuilding of the overhead work on the New Orleans & Carrollton Railway at New Orleans, La. A number of large photographs showing the company's material in use on roads in different parts of the world, completed this attractive exhibit, which was in charge of its superintendent, G. R. Scrugham. A steel pocket rule was given as a souvenir.

A. MAJOR, of New York, exhibited two useful and valuable articles. One of these is Major's cement, which is known throughout the country and extensively sold by druggists. Mr. Major discovered it in 1876 and put it on the market; it has had an increasing sale ever since. The other is an economincal arrangement for water-coolers. It is a receptacle that can be used in any water-cooler. With it in the cooler, the ice melts only half as fast and keeps the water at the temperature of cold spring water. It is now used by a number of prominent firms who approve of it and recommend it highly. Their testimonials state that the receptacle does everything Mr. Major represents it to do. The superintendent of one of the largest of Edison's electric plants in New York City stated to Mr. Major that since the receptacle has been used, not one man in the engine or boiler room has suffered from the effects of ice water. It also accomplishes a great saving in ice.

THE W. T. VAN DORN COMPANY, of Chicago, showed eleven patterns of couplers for cable, electric and elevated roads. Full-sized couplings for all these classes were shown in detail. Also two sizes of Mr. Van Dorn's well known ball joint. Two small cars fitted with Van Dorn's No. 5 complete with ball joint, made up the remainder of the exhibit. Visitors at this booth without exception pronounced the Van Dorn coupler perfect.

THE STAR BRASS WORKS, of Kalamazoo, Mich., had a neat booth in charge of Walter C. McKinlock. This company's trolley wheel, which has been on the market not quite two years, is running on thousands of cars. Some of the points of superiority claimed for it are as follows: It will run in sleet longer than any other, is self-oiling and therefore saves bushings, will run smoother and last longer, is a good conductor and is not complicated, will not injure the overhead equipment, is made in the standard sizes, 4 ins. and 6 ins., and will fit any standard harp.

THE GARL ELECTRIC COMPANY, of Akron, Ohio, represented by M. Garl, had on exhibition its street railway phones, which have been described in the JOURNAL in the past. The company has just bought out a new portable pocket phone which the motorman may carry in his pocket. The transmitter and receiver are all fastened together in one piece, the receiver forming a cap over the transmitter. When needed, the cap is removed and the phone plugged in at the stations along the line. The phone complete weighs only a pound. The company also showed house phones, and an ingenious fire and burglar alarm, which explodes a blank cartridge when disturbed by either fire or burglars. The cartridge serves the purpose not only of attracting the owner's attention, but of frightening the burglar as well.

THE AMERICAN VITRIFIED CONDUIT COMPANY, of New York, was disappointed by not receiving the material intended for its exhibit in time for making the extensive display, as originally planned. The company showed a few samples of its self-centering single and multiple ducts in its standard types of conduits for street railway and lighting service. The company was represented by B. S. Barnard.

CLIFT WISE, of Chicago, known to convention goers for the past fifteen years as one of Chicago's street railway contractors, was on hand as usual.

THE NORTH AMERICAN RAILWAY CONSTRUCTION COMPANY, of Chicago, had its interests cared for by A. S. Littlefield, president; D. J. Evans, secretary, and E. M. Fry, general superintendent. This company has had an immense amount of

work on its hands this summer, among its contracts being 25 miles in Indianapolis, the track work for the Northwestern Elevated in Chicago, and extensions of the Metropolitan Street Railway, of Kansas City, and the Chicago & Milwaukee Electric Railway.

THE STANDARD RAILWAY SUPPLY COMPANY, Chicago, was present in the person of its president and general manager, Garson Myers. This company represents the Christensen Engineering Company, R. D. Nuttall Company, Albert & J. M. Anderson Mfg. Co., Du Puy & Company, and others.

PIERCE & RICHARDSON, of Chicago, the well known Western contractors, were represented by the three gentlemen who comprise this firm: Richard H. Pierce, Robert E. Richardson and Samuel G. Neiler. This company acts strictly as consulting engineer, not being interested in nor handling any manufactured products. Among the company's clients are Armour & Company, Salt Lake (Utah) & Mercer Railroad, and the Chicago City Railway.

THE COMPRESSED AIR MOTOR COMPANY, of Chicago, had a small booth from which it issued its handsome new catalogue. Those of the company present were Henry D. Cooke, president; William E. Selleck, general manager; Robert Hardie, engineer; C. V. Kasson, head of sales department. This Company's compressed air system for operating street railway cars has often been discussed in the columns of the STREET RAILWAY JOURNAL. Air cars have been running in Chicago since May 30, 1899, and have performed continuous and uniformly satisfactory service. One interesting peculiarity about this operation is that on the first trip each night the run is made with air stored over from the previous run, and it is not unusual to attach one trailer, and sometimes two trailers.

THE SWARTS METAL REFINING COMPANY, of Chicago, is a name well and favorably known to street railway people throughout the entire country. This company has built up an immense business in the handling of worn-out trolley wire, scrap windings, brass castings, etc., etc. The company also furnishes a superior metal for motor bearings, which is coming into general use on the best roads. The company was represented by its president, S. Swarts.

SARGENT & LUNDY, of Chicago, known as engineers for many of the largest steam plant installations in the West, were present in the persons of Frederick Sargent and A. D. Lundy, neither of whom needs any introduction to street railway men of the present day. This company is retained as consulting engineer for a large number of the railways now being constructed in the West.

THE HEINE SAFETY BOILER COMPANY, of St. Louis, was present in the person of its genial Chicago representative, James H. Harris, who has represented this firm in Chicago for nearly twelve years, during which time he has been one of the best known among steam supply men.

NAUGLE, HOLCOMB & COMPANY, of Chicago, the contractors who built the Suburban Railroad in Chicago, and who are at present constructing 250 miles of the Tennessee Central Railway, much of which is through the roughest part of the Tennessee Mountains, were represented at the convention by E. E. Naugle. This company is the largest producer of ties and poles in the West, and has an enviable reputation for experience and reliability.

THE SPIRAL JOURNAL BEARING COMPANY, of St. Louis, exhibited with the Morris Electric Company its new motor bearing, which consists of an iron shell lined with two dissimilar metals, brass and anti-friction, so placed that the journal has a continuous bearing on both metals. From this combination it is claimed that a greater mileage is obtainable than from either a solid bronze or babbitted bearing. The company guarantees to replace without charge all spiral bearings removed from service on account of heating or breaking before wearing out. L. P. Delano, president, represented the company.

EXHIBIT OF WM. WHARTON, JR. & CO.

THE CYLINDORAMA RAILWAY COMPANY showed a new attraction for parks, which consists of a revolving steel cylinder 200 ft. long x 50 ft. in diameter, which contains forty convolutions of tracks, running around the inside of the shell. The cars, of which forty can be operated continuously, are held at the bottom of the cylinder by the action of gravity, but appear to the passenger to be running at great speed, due to the revolution of the cylinder. The cylinder is fitted with scenery, tunnels, bridges, etc. It is believed that this new park attraction cannot fail to meet with very great success. Samuel Barnes, secretary and general manager, and Harry J. Armstrong were in charge.

EXHIBIT OF OHMER REGISTERS

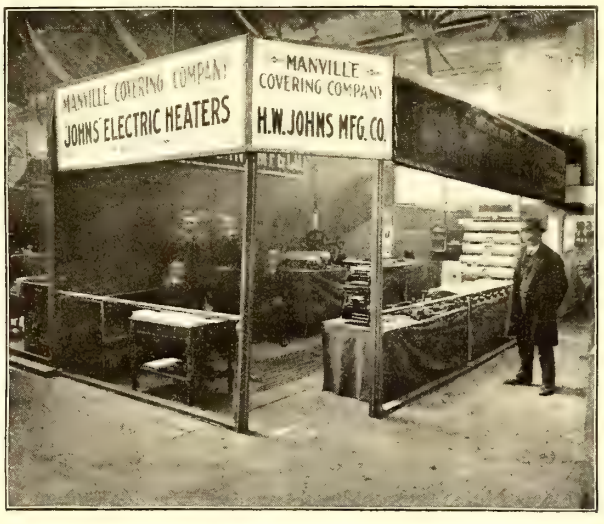

EXHIBIT OF JOHNS' ELECTRIC HEATERS

THE WESTERN ELECTRICAL SUPPLY COMPANY, which has rapidly built up the largest business in the Southwest in the handling of street railway supplies, was represented by the manager of its street railway department, Charles Scudder, Jr.

THE CENTRAL UNION BRASS COMPANY, of St. Louis, was represented by its manager, T. C. White. This company is bringing out an extensive line of overhead material and making

a special drive for street railway business. Mr. White reports that his factory is very busy and that the company's new material is meeting with much favor from street railway companies.

A. C. BECKEN, of Chicago, exhibited a case of Paillard non-magnetic watches, which, it is claimed, are absolutely uninfluenced by magnetic action. These watches are handsome and durable and accurate time-keepers.

THE SIEGRIST LUBRICATOR COMPANY, of St. Louis, had its booth enlivened by one of the best "coon" orchestras in town, whose good music and singing attracted and entertained a continuous crowd. The company's booth was a handsome one, decorated in purple. There were exhibited automatic oil cups and automatic sight feed lubricators, also a double automatic lubricator which has the advantage of two passages for the feeding oil, removing in a large measure the danger of stoppage on account of an obstruction in the oil passages; also the company's standard automatic oiling table. The company's manager, J. N. Edelin, was present with a constant supply of good cheer for his friends.

THE ALLEN & MORRISON BRAKE SHOE & MANUFACTURING COMPANY, of Chicago, showed its composite brake shoe, which was brought out some two years ago, and which is already well known to the trade. This shoe is in service on a great many lines and giving excellent satisfaction. A. M. Allen, J. H. Miller, F. R. Spear and F. D. Freeman, of the company, were present.

THE AMERICAN BRAKE SHOE COMPANY, of Chicago, illustrated the construction of its " Diamond S" brake shoe with sectional broken and complete shoes. The "Diamond S" is in service on a large proportion of the cars, both steam and electric, throughout this country. Representatives of the company were F. W. Sargent, W. D. Sargent, George H. Sargent, A. T. Herr, H. H. Haskell, J. W. Gardner, Arthur Gemunder, G. C. Isbester. The Sargent Company, of Chicago, displayed in this booth a number of steel castings. This company has for years furnished for street railways everything in the line of steel castings.

THE CURTAIN SUPPLY COMPANY, of Chicago, displayed all kinds of curtain fixtures, in a full-sized car model. The company will soon issue its new catalogue. This company, which bought all the old companies in the business, now controls all the curtain fixtures made. Those of the firm present were W. H. Forsyth, G. H. Forsyth, F. C. Kenly and A. L. Whipple.

THE HANNA SOLID OIL COMPANY, of Chicago, although a new company in the field, is becoming well known through its manager, J. W. Hanna, who was often seen at the Convention Hall.

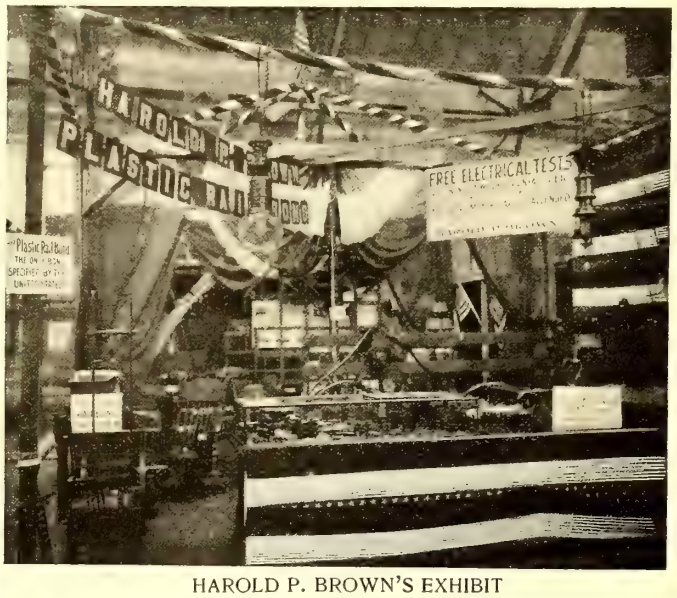
HEYWOOD BROS. & WAKEFIELD COMPANY, of Wakefield, Mass., made a very good exhibit of car seats of the Wheeler, Bushnell and Henry patterns. The special feature of the display was the "walk-over" seat, which was shown in leather, rattan and plush finish. The claims made for this seat are its simple mechanism and its neat appearance. The seat department of the exhibit was in charge of Bertram Berry, of New York, and James Hitchcock, of Chicago. The company also showed a new time recorder for use in car shops or factories of any kind where a large number of workmen are employed. Those interested were supplied with a handsome catalogue and samples of the records made by the recorder. This part of the exhibit was in charge of R. E. Kimball, of Chicago.

EXHIBIT OF THE GENERAL ELECTRIC CO.

THE DIAMOND STATE STEEL COMPANY, of Wilmington, Del., made an interesting exhibit of some of its track specialties, among which may be mentioned the Churchill girder and T-rail joints, the Diamond spike, the Diamond crescent spike, the Diamond tie-plate and the automatic rail joint spring. The Churchill girder rail joint was shown in full and also in cut sections, exhibiting the perfect union of parts and the wedged underbearing, preventing any movement of the rail ends and thereby eliminating wear. Blocks of wood illustrating the cutting of wood fiber by the Diamond spike, as compared with the ordinary pressed and even rolled point spikes, presented a striking contrast which attracted considerable attention. The automatic rail joint spring, which has already proven its effectiveness in steam railway practice, is claimed to add largely to the strength of channel as well as T-rail joints, and are invaluable in crossings where bolts tend to loosen and break. The Diamond tie-plate is a modification of the well known Servis type with longitudinal under flanges and projecting fluted web to shield the flange ways from water dripping from the rail. The company was represented by

W. S. Boughton, treasurer, formerly with Lorain Steel Company, and Benjamin Reece, engineer.

THE INTERNATIONAL REGISTER COMPANY, of Chicago, made a very handsome exhibit of its well known machines. The company was represented by A. H. Woodward, president; W. H. Brown, secretary; A. H. Place, W. J. Volkins, vice-presidents; A. H. Englund, of Philadelphia, and Charles N. Wood, of Boston. The features of the exhibit were the standard single register, with aluminum face, designed for one class of fares, and the double register for any two kinds of fares, such as tickets and cash, transfers and cash, five-cent and ten-cent fares or any other two classes as may be required. Any of these registers may be fitted with any style of pulls, cord or rod, and for any type of open or closed car. The double registers are fitted with two bells of different tones. Some of the registers shown were made with the aluminum face, others with black face. The exhibit included a full line of register fittings for both rod and cord, such as handles, pulleys, brackets, rods, etc. There was a great demand for the company's small portal scale souvenir, which was one of the most practical souvenirs at the convention.



THE OHIO BRASS COMPANY, of Mansfield, Ohio, made a very handsome exhibit, which was well arranged and was very comprehensive. The company was ably represented by three men from the Mansfield office, and one from the New York office. These were C. K. King, secretary; A. L. Wilkinson and G. A. Mead, of Mansfield, and R. A. Byrns, of New York. The arrangement of the display was well calculated to show off the material to good effect. Surrounding the space were placed both wood and iron poles, equipped with two styles of iron brackets. The brackets included the company's well known flexible brackets and these were fitted with hangers of the various types required in actual service. One pole was equipped with a flexible bracket on which the suspension yoke was fitted for supporting two parallel trolley wires. A full line of clamps and ears for figure 8 wire were shown, including a greater variety than ever before exhibited by the company. The insulating material used in the entire exhibit was of the Ohio Brass Company's well known standard type known as "Dirigo." Mention should be made of the very fine sample board which formed the background of the exhibit, made up of a well arranged display of small line material in a great variety of styles. A full line of feed-wire fittings was also shown. The entire central part of the company's space was taken up by a pyramid of steps, on which all small parts were displayed in great profusion. Besides this elaborate exhibit of line material the company also showed a variety of other supplies, such as headlights, ratchet brake handles, bell-metal motor bearings, track brushes and brush holders, the Monarch track scraper, gongs, bonding caps of steel and copper, etc., etc.

THE WATSON-STILLMAN COMPANY, of New York, had a practical exhibit which included a motor lift for pit work with a capacity of 3000 lbs.; hydraulic rail punches, suited for punching a hole 1 in. in diameter in 1-in. iron; swivel jacks of 7 tons and 10 tons capacity; hydraulic T-rail bender, and a hydraulic girder rail bender.

THE GENERAL ELECTRIC COMPANY was in full force with a large delegation from its various offices and factories. The delegates who attended were S. D. Greene, S. Trawick, George Rosenthal, E. D. Mullin, T. P. Bailey, R. H. Beach, F. W. Willcox, F. E. Case, F. H. Strieby, A. H. Armstrong, W. F. Hayes, B. E. Sunny, F. Barbour, W. J. Ferris, E. D. Priest, J. J. Mahoney, F. M. Kimball, R. A. Swain, George J. Cadwell, J. W. Johnson, W. B. Potter, F. N. Boyer, J. G. Barry, J. W. Buell, J. H. Livsey, H. R. Bishop, Jr.; George Breed, R. E. Moore, W. G. Carey, T. Ferris, Ward S. Arnold. The exhibit comprised two GE-55's mounted on a truck, which are to be used as an equipment for the Northwestern Elevated Railway. These motors are of 150-h.p. capacity. In addition, there were two GE-100's, equipped with the B-13 controller and electric brakes. The motors and brakes were mounted on a St. Louis Car Company's truck. One of the special features of the exhibit was the new GE-65 of 250 h.p. capacity. This motor was built expressly for the Paris & Orleans Railway, Paris, France. The exhibit of street car motors comprised a GE-52 and also a 57. A line of stationary motors was also shown, the new C. E. type being displayed. There was also an air compressor which the General Electric Company is building for elevator work. A line of standard switchboards also attracted much attention as showing the latest type for feeder panel boards. This part of the exhibit included two standard generator panels and an additional panel whereon was mounted a form G-2 station wattmeter. A large line of supplies of overhead material, circuit breakers, lightning arresters, assembled commutators, armature coils and porcelain insulators similar to those used on the third-rail system were also displayed.

EXHIBIT OF THE FALK CO.

HAROLD P. BROWN'S EXHIBIT

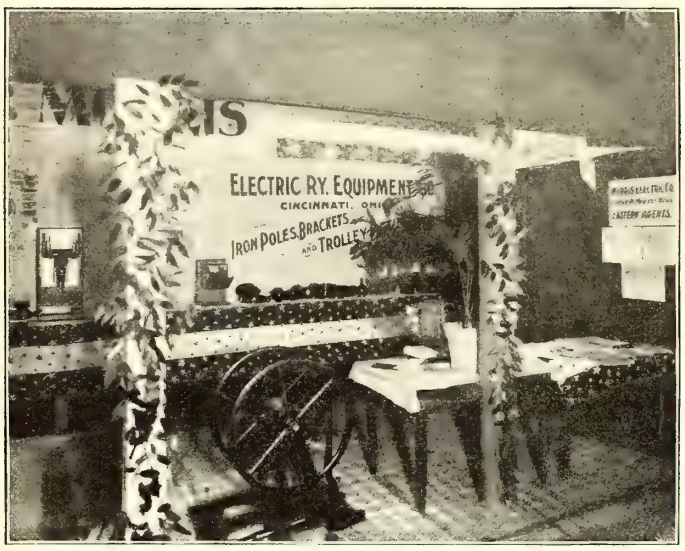
THE NEW HAVEN CAR REGISTER COMPANY, of New Haven, Conn., showed, in addition to its well known regular line of "New Haven" single, double and triple registers, its new round single and double registers, which the representatives of the company present claimed are the most complete, and in every respect, the finest round registers ever made. These machines are constructed in a very thorough manner, and are said to contain all the recognized desirable features, and in addition special and valuable points which none of the other makes possess. The completeness of the double register, which consists of two single registers in one case, is recognized at a glance, and the many unique features, such as showing the number of the trip, as well as the direction, the number of each class of fare rung up on the trip up to 1000 in large numerals, which can be plainly read from end of longest car, the total number of each class of fares up to 100,000, and indicating the class of fare last rung up in prominent letters, were appreciated by all practical railway men. Each machine is also provided with red safety shields and with automatic locking and controlling devices, preventing one side of register from being rung up while the other side is being operated. A locking device is also provided so that conductors can lock the register upon temporarily leaving car, preventing the ringing of any fares during their absence. This register is also adapted for use on two connecting roads, one side for each road, each conductor securely locking his side of register when leaving car. It can also be arranged as two separate registers, each side operating and being reset to zero independent of the other side. All these

different arrangements make this machine peculiarly adapted to meet the various conditions of registering fares on electric railways. The round single registers are provided with very prominent numerals and the safety shield is lettered "not registered." This shield covers the figures as soon as the conductor begins ringing up the fares, and remains in view until after the fare is rung up and registered. This machine has been adopted by the Third Avenue Railroad, of New York, on its new equipment. Both of these registers, in addition to being very complete, strong and durable, presented a very fine appearance with finely finished antique copper cases and ornamental aluminum dials and attracted much attention at the convention. The different parts of the New Haven registers were also shown mounted on boards, together with the "New Haven" simplex and duplex counting machines, used in commercial business for any kind of counting records. The representatives of the company at the convention were J. S. Bradley, president; F. C. Boyd, W. M. Anthony and H. E. Beach.

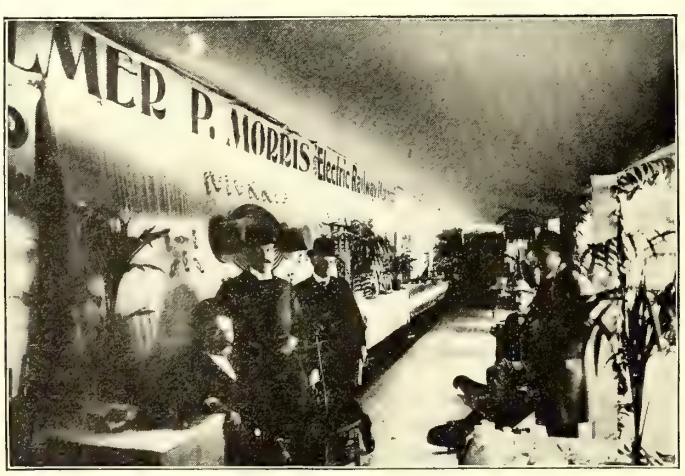
VIEWS TAKEN NEAR THE CENTER OF THE HALL

THE EUREKA ELECTRIC COMPANY, of Chicago, had a compact and comprehensive exhibit of its telephones, and called special attention to its excellent telephonic apparatus for railway

work, emergency purposes, etc. It was a shrewd idea to make such a display and it attracted much attention on the part of the managers and superintendents of roads. The exhibit was in care of I. J. Kusel, president; H. J. Kusel, vice-president, and Arthur Stein, secretary and treasurer. They are to be congratulated on the display made and the effect created.



SOME VIEWS TAKEN IN DIFFERENT SECTIONS OF THE HALL



W. R. BRIXEY, manufacturer of Day's kerite wires and cables, was represented by G. F. Porter, New York manager, who had samples of this product with him. This company has recently taken some of the big orders in the street railway line.

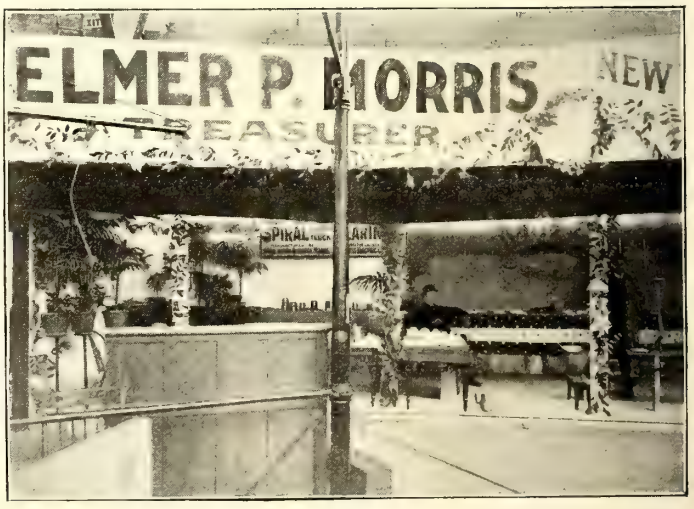
THE PITTSBURGH REDUCTION COMPANY had one of the smallest exhibits in the place, but it was decidedly one of the most novel and interesting. It consisted essentially of a large glazed frame holding an assortment of its aluminum wires and cables, which of late have made so distinct a place for themselves in electrical transmission and allied work. A few samples of other aluminum goods were also shown by J. A. Rutherford, representative.

THE FRANK RIDLON COMPANY, of Boston, was represented by Chas. N. Wood, who exhibited a Wilson trolley-pole catcher, which he showed in operation with a Nuttall pole. The

compact little round box containing the roll-up machine is easily attachable to the dashboard and the cord is held at the point where the conductor sets it, so that his mind and hands have greater freedom to attend to his more legitimate business of looking after the passengers and collecting fares that would otherwise be missed. The attachment is inexpensive, simple, and does not get out of order. It not only prevents trolley-pole accidents, but it keeps out of sight all the cord that is otherwise a nuisance by dangling idly. Testimonials that it kept the pole in position were shown from those using the device, testifying to its value on trolley cars, particularly in places where the high speed of running was likely to throw the trolley off.

THE TAUNTON LOCOMOTIVE MANUFACTURING COMPANY, of Taunton, Mass., was represented by W. R. Billings, treasurer; J. C. Sproat, J. H. Wright, agent, Lancaster, Ohio, and Messrs. Wendell & MacDuffie, both of these New Yorkers being also on hand. The exhibit was made wholly in the open air, and comprised a double-truck share snow plow, a nose plow and a snow sweeper, the last being the company's initial attempt in this direction. The double-truck plow has a long leveler that can be swung out widely from the cars, and which can level down the snow for carting away, sleighing, etc. Some seventy of the plows have been sold this year. The sweeper shown was sold to the Cleveland, Painesville & Eastern road. It has several notable features. The weight is about 11 tons, and the main sill is 11 ins. x 4½ ins. The heaviness of the sill gives strength, but with this go adjustability and the keeping of the sill level, even after years of service. Friction clutches are used on the broom motor shaft, and the brooms have malleable iron heads with extra heavy rattan in the brushes. There are extra heavy accessories and arrangements for the draw-bar, and specially heavy and long leveling wings on each side which can be quickly opened and shut. A first-class digger is supplied. The machine presented a most solid and massive appearance.

ALEXANDER H. LEWIS, Cincinnati agent for the Cahall boiler and the Kilgour safety brake, was in evidence for the first two or three days.



THE GOLD CAR HEATING COMPANY, of New York, had an effective and attractive display of its well known electric heaters, tastefully grouped and showing details. The exhibit included complete lines of this company's street car heaters and the types for house, office and apartment heating. The company was well represented, its forces on the ground including E. E. Gold, president; John E. Ward, general manager; Egbert H. Gold, Western representative; F. Weston, New York, and J. Watson and T. Downing, Western salesmen. A large business was done at the booth, which was visited by the delegates in great numbers, and the company was elated as to the victory recently achieved by it in the courts, and in regard to which a special circular was issued. The company, which has quite a reputation in the souvenir line, gave out liberally a choice leather pocket note-book, with many features of desirability.

THE CONSOLIDATED CAR HEATING COMPANY, of Albany, N. Y., had an attractive exhibit on the main aisle under the care of R. S. Scales, Western representative; W. P. Cosper, general agent at St. Louis, and J. H. Dubarry, Jr., of New York City. The heaters were shown separately, in detail, and in operation, under longitudinal and cross seats. Special attention was directed to the new three-point switch with a dial, which indicates visually the steps in throwing on the heaters and heating the car. Along the back of the booth or space the gratings of the heaters were used to mask some colored incandescent lamps under mica, giving a very pretty effect.

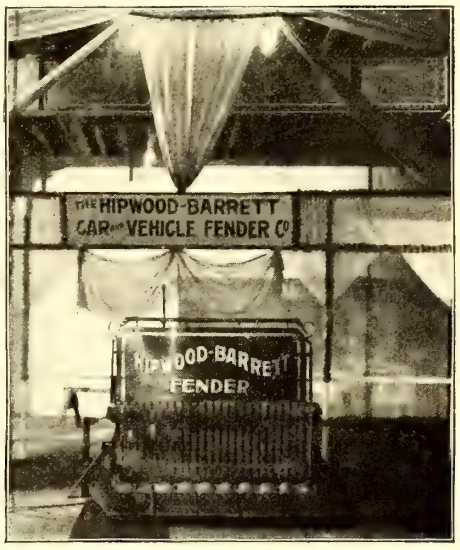
C. S. KNOWLES, Boston, a well known supply dealer, was ably represented by Percy Hodges, who is in charge of the street railway department.

THE STANDARD AIR BRAKE COMPANY, of New York City, was represented by J. R. Ellicott, general manager; E. H. Beacham, and G. E. Baker, of New York. The exhibit was very complete, illustrating thoroughly the application of mechanical brakes in the street railway service. It included three types of service, one with the motor driven compressor, one the gear driven and the third showing the eccentric driven. The independent motor driven compressor, which was fitted with a Storey motor, was admirably demonstrated, and the various parts were all available for examination, including compressor, automatic controller, cylinder, reservoir, operating valve, platform staff, etc. The automatic was set at 60 lbs., cutting in at 45 lbs. The other type cuts out at 90 lbs., and cuts in at 80 lbs. The interest shown by large throngs proved that while air brakes are still unfamiliar to many people in street railway work, the resort to them is rapidly becoming general and is encouraged by public opinion. Handsome catalogues were distributed and instruction books to those who could benefit by them.

J. G. WHITE & COMPANY, electrical engineers, etc., of New York, distributed a handsome brochure in which the statistics of the growth of electrical industries in the United States are presented very concisely. The total capitalized value is put at over $3,000,000,000, half of which is to be credited to electric railways alone, all due to the development of electric traction in the last ten years.

SNAP SHOTS OF THE MORRIS EXHIBIT

THE CHARLES SCOTT SPRING COMPANY, of Philadelphia, was represented by D. L. Roche, of that city; Scott R. Hayes, of Cleveland, and J. T. Harahan, Chicago. This com-



pany's compact exhibit included specimens of the various branches of its work, particularly a full line of springs for trolley trucks and trolley stands, as well as valve springs. At a central table stood a large nickeled spring, of the kind made to go under steam passenger coaches. Around the exhibit smaller springs were mounted on wooden pedestals for better inspection. The company distributed among its friends a valuable card case pocketbook in leather.

THE TAYLOR ELECTRIC TRUCK COMPANY, of Troy, N. Y., exhibited one of its heavy 8-ft. wheel base single trucks, designed for heavy vestibule single-truck cars, one of its Empire State radial trucks, one of its swing bolster double trucks for regular double-truck passenger car service, and a recently designed extra heavy swing bolster double truck, for long, heavy, high-speed suburban cars. The exhibit was in charge of John Taylor, manager of the company, and the Taylor trucks were thoroughly examined in detail and highly spoken of by many delegates. Of the extra heavy swing bolster style, sixteen have been ordered for Ottawa, Canada, while six long car sets have been sold to the Quebec, Montmorency & Charlevoix Street Railway.

THE R. D. NUTTALL COMPANY, of Allegheny, Pa., had a large space and was represented by F. A. Estep, president, associated with them in its occupancy being the Standard Railway Supply Company, Garson Myers, president, and C. N. Wood, of Boston, with whom was C. W. Held. The Nuttall exhibit included a variety of the trolley poles, springs, gears, pinions, etc., of the company's familiar make. The motor gear cutting plant owned by this company gives it unusual facilities in that line and the product

EXHIBIT OF THE STANDARD AIR BRAKE CO.

THE HIPWOOD-BARRETT FENDER

has thus won the reputation deserved by every piece shown in the exhibit.

F. B. BROWNELL, of the Brownell Car Company, St. Louis, was in attendance through the convention.

THE EXHIBIT of the Lorain Steel Company, of Lorain, Ohio, spread out over almost one entire end of Tattersall's, and needed the space taken for this varied display, which in many respects was one of the most comprehensive in the whole hall, as it ranged from car controllers and motors to the details of track construction. The exhibit was in charge of P. M. Boyd, of Lorain, secretary; S. P. S. Ellis, Pittsburgh; F. A. Merrick, Johnstown; W. W. Kingston, Atlanta; R. T. Lane, Johnstown; A. S. Littlefield, Chicago; O. C. Evans, Cincinnati, and H. C. Evans, of New York. The exhibit included, in the truck department, the company's new double truck, "style F," and its new single truck, "style C," the double taking two 50-h.p. "steel" motors, and the single two 35-h.p. "steel" motors, constituting a very substantial, but flexible mechanism. In the rail and crossings department were shown the company's guaranteed 9-in. switch pieces, with hardened plates, Lorain standard crossings and a remarkable 9-in. girder crossing with the continuous arms made in two pieces, so that there is only one pair of joints in it. Note must also be made here of the beautiful examples shown of electric welds, taken from real practice on 6-in. 66-lb. rail, recently, at Buffalo. The company also showed two of its new controllers, for which many points of excellence and uniqueness are made, and which are strikingly compact, simple as to wiring, easy of access, and renewability of working parts, which greatly simplify the work of the motorman. The single controller of this type for two motors up to 35 h.p. each was attached to one of the trucks and in operation. The double controller shown will take care of four motors up to 35 h.p. each, and is practically two motors rolled into one. The controllers were a subject of much interest on account of their originality and were in constant operation by the company's experts.

THE JACKSON & SHARP COMPANY, the well known car builders of Wilmington, Del., was represented by J. Monteith Jackson.

THE HIPWOOD-BARRETT CAR AND VEHICLE FENDER COMPANY made an exhibit which probably attracted as much attention as any in the hall, partly because of the intrinsic merit of the fender, and partly because it was accompanied by one of the most ingenious and effective devices for showing the working of a piece of apparatus ever seen at a convention. This was the "mutascope," by means of whose 1200 photographs, taken at the rate of forty per second, a car equipped with the Hipwood-Barrett fender is actually seen approaching the spectator at the rate of 15 miles an hour, while in the course of its travel it picks up two 65-lb. child dummies, one standing erect on the track, the other prostrate with one arm extended in the direction of the approaching car—conveys them a few feet further till the car can be stopped —and then is shown the operation of closing up the fender and running it out of the way under the car. The Hipwood-Barrett fender is constructed on the principle of providing yielding striking surfaces, by which the blow to the "strikee" is greatly lessened, and he is landed safely upon the fender. It is stated that the 65-lb. dummies shown by the mutascope, which are made of ordinary canvas, filled with sand, have been struck and captured by the fender 104 times to date without at any time tearing or ripping the canvas. As souvenirs of the convention, the company presented to its friends several circulars descriptive of the fender, together with a beautifully gotten up little souvenir showing pictures of all the challengers and defenders of the America's cup since the latter was first won in 1851. The European patents of this company have recently been sold to Frederic Romünder, of Cologne. The company was represented by A. B. Dalby, president; George Hipwood (inventor of the fender), treasurer; George Weiler, Western manager, and Henry S. Jenkins.

THE OHMER REGISTER COMPANY exhibited, as its principal feature, a complete working installation of a ten-fare Ohmer register with auxiliary apparatus, and this was examined with the greatest care by some of the principal street railway managers and auditors attending the convention, several spending an hour or more in watching the operation of this peculiar and valuable invention. The register has been brought to still greater perfection during the past year, and is now a very simple and highly efficient machine. Its principal mechanism is of malleable iron, and springs have been almost completely done away with, the action of the conductor's cord being to raise the iron parts to the point where the record is taken, these parts returning to their original position by means of their own weight. The counters are also simple and well made, and by an ingenious mechan-

ism, a record may be taken at the end of every single or round trip, or at any time, in such a way as to form a perfect check upon the conductor. This feature, joined with that of the multiple register plan of construction for registering different classifications of fares, transfers, etc., makes it possible to greatly simplify the work of the auditor's department, and at the same time that of the detective force, in ways which have already been quite fully explained in the STREET RAILWAY JOURNAL. Moreover, the method of ringing up fares by the conductor provides a "visible receipt" similar to that given by the cash registers now in common use in stores, and the system devised by the company for recording the different

EXHIBIT OF K. M'LENNAN & CO.

kinds of cash fares, transfers, etc., makes it possible to not only detect dishonesty in the case of any single conductor, but to find out who is his confederate, if any, together with the method employed by them for "beating the company." The Ohmer register will find a wide field, especially in interurban work in America and upon foreign tramways, where several different rates are charged, and one feature which gives it additional value abroad is that it can be used on double deck cars with almost the same advantage as with single deckers. The company was represented at the convention by John F. Ohmer, president and general manager; J. H. Stedman, secretary; H. Tyler, superintendent of manufacture; William F. Breidenbach, Western manager, and E. M. McDonald, and A. N. Loper, traveling agents. Mr. Stedman, the company's secretary, has recently become financially interested, and through his wide acquaintance and popularity will, undoubtedly, add great strength to the company.

THE CONTINUOUS RAIL JOINT COMPANY OF AMERICA made an exhibit consisting of several T and girder rail sections fitted with their joints, and showing well the admirable character of the work which this company does. Ordinarily, it is not an easy thing to make three fits with a fish-plate, one to the bottom of the rail, a second to the top of the base, and a third to the under side of the head, but the Continuous Joint is so carefully rolled as to make these fits absolutely perfect, and when this is done there is no question as to the strength or value of the joint, which is very popular among steam railroads, and might readily find wide use in street railways. The company was represented by J. F. Braine, general manager; William F. Ellis, New England agent; H. M. Montgomery, Western agent, and F. C. Schmitz, New York agent.

THE CONSOLIDATED CAR FENDER COMPANY exhibited not only its well known fender, which is undoubtedly the most widely used of any in the United States, but also showed a new step lifter for open cars, by means of which the motorman can easily raise or lower the step from the platform at the end of the trip, and also, when necessary, in passing through crowded streets, and the Campbell snow broom, which is a great improvement over the brooms ordinarily in use. The broom head is made in sections of malleable iron, and the rattan is passed through holes specially prepared for its reception and firmly held in place. It is claimed for this broom head that it will outlast an immense number of those ordinarily in use. The company distributed at the convention a number of bright and taking souvenirs, one of which, especially, was in great demand among the supply men as well as the delegates, and created much amusement. Another contained a Chinese coin given in the hope that "As a pocket piece it may serve as a charm against accidents and misfortune, and be a continual reminder of (the Providence) Fen-Der, a great magician and astronomer of ancient China." Other souvenirs were a small leather covered mirror and a mirror of a different pattern. The company was represented by Col. A. C. Woodworth, general manager, and George Hollingsworth, superintendent.

THE COLUMBIA MACHINE WORKS, of Brooklyn, N. Y., made an exhibit of a few of its street railway specialties, and was represented by W. R. Kerschner.

F. E. DONOHOE, Western agent, and E. H. Hammond, of the Chicago office, represented the American Electrical Works at Providence.

THE PENNSYLVANIA STEEL COMPANY, of Steelton, Pa., had its interests in the care of M. D. Pratt and C. S. Clark, the former being the company's street railway engineer and the latter its Boston manager. The entrance to the exhibit was framed by a huge arch of the company's No. 250 9-in. rail, weighing 128 lbs. to the yard, and the piece thus shaped into a perfect semi-circle of 12 ft. radius weighing about 2000 lbs. Among the samples exhibited were pyramids of rail sections, one column being T-rail and the other girder, through the range of from 12 lbs. to the yard up to 128 lbs. There were also samples of the company's regular Adamantine cast steel special work in frogs, switches and switch stands, and of the Adamantine worked up this way on T-rail frogs and switches using 60-lb. rail. A most interesting feature, both by its suggestiveness and by its relation to export trade, was that of the steel ties to be bedded in cement and intended specially for use on tropical roads, where the conditions are adverse to longevity in wood. With the tie were shown also the drop forged steel brackets used in the work. This style of construction will go on the Sao Paulo (Brazil) road, and is in requisition also for Australia.

THE M'GUIRE MANUFACTURING COMPANY, of Chicago, had, as usual, a very fine, comprehensive and complete exhibit, both within Tattersall's and outside, and was represented by a large staff, at the head of which were W. A. McGuire, president; W. J. Cooke, vice-president; W. P. McGuire, and E. E. Cook, superintendent. The exhibit in the hall covered a large space and comprised two No. 39 trucks, one elevated truck, one solid steel Columbian truck, six ratchet brake handles and six new

EXHIBIT OF EUGENE MUNSELL & CO. AND MICA INSULATOR CO.

Columbian car heaters. A great deal of interest was taken by experts and the public in the "A1" suspension truck shown, bearing a sign to the effect that it was one of 120 ordered for the Havana Electric Railway, and which is also of the type of which the New South Wales Government has bought 230. Of the No. 39 and the solid steel, the company also reported that it was exporting a number to Germany. An interesting feature of this exhibit, and one which attracted great attention, was a pair of side bars of the truck which had been twisted to form a spiral, then bent double. This showed the great ductility of the cast steel used and ability to withstand fracture. Outside the hall, the company had a 14-ton

electric snow sweeper, of which fifty-seven have already been sold this year, fourteen of them going to one road in St. Louis. In addition to the material included within its exhibit proper, the McGuire Company had auxiliary exhibits, so to speak, in the spaces of the General Electric Company and the Westinghouse Company, where railway motors carried on its trucks were in actual operation.

THE BADT-GOLTZ ENGINEERING COMPANY, of Chicago, comprising F. B. Badt and William Goltz, was conspicuously represented by the former, who was not only in constant attendance at the exhibition, but entertained friends in off hours at the Union League Club. Mr. Badt was quite busy with the delegates in regard to Weston instruments, Leonard rheostats and signs, Helios lamps and Edison-Brown plastic bonds. He had as a souvenir a handy pocket calendar for 1899-1900.

THE SIEMENS & HALSKE ELECTRIC COMPANY, of Chicago, was glad to welcome numerous visitors at its fine factory during the convention, but did not make an exhibit. The company was represented on the floor of the house by W. G. De Celle, W. H. Abbott, C. E. Wilson, W. R. Mason, of St. Louis, and Alex. Churchward, its electrical engineer.

THE JOHN A. ROEBLING'S SONS COMPANY, of Trenton, was very much in evidence all the time, not so much by exhibit and sample or souvenir, as by the indefatigable efforts of its large staff, which comprised M. R.Cockey, G. W. Swan, H. Jenkins, A. B. Conover, A. M. Whaley, H. E. Fisher, W. G. Tingley and W. P. Bowman, each paying attention to the roads represented from his respective territory.

EXHIBIT OF THE CENTRAL ELECTRIC CO.

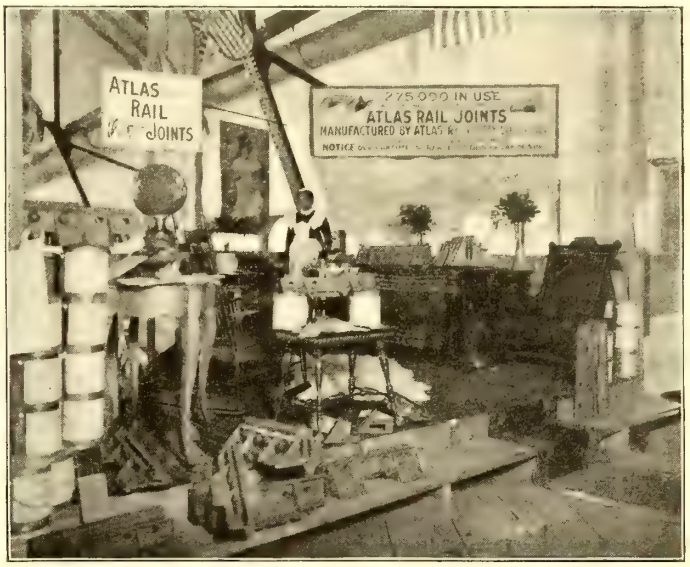


EXHIBIT OF ATLAS RAIL JOINTS

ROSSITER, MACGOVERN & COMPANY, of New York, were represented by Frank MacGovern and John A. Steuart, the Western representative. Mr. MacGovern was an assiduous attendant at the exercises of the convention and gave close attention to matters coming within the field which he has made specially his own. The changes in apparatus and his recent venture in the acquisition of the Excelsior Electric Company's manufacturing plant have brought Mr. MacGovern into touch with so many railway men that he had no time for social distractions except in their company.

THE SAFETY INSULATED WIRE & CABLE COMPANY, of New York, was represented by Lieutenant E. J. Spencer, of St. Louis, who had a well appointed booth. With him were associated M. B. Austin and A. B. Brown, of Austin & Brown, the Chicago agents. A very good display was made of some twenty special wires and cables, running up to the largest sizes. For example, there were shown sections of the cables made for the Chicago elevated roads, equalizer cables employed in Chicago railway power-houses, and the 6000-volt three-conductor three-phase cables of the Metropolitan Company. The Niagara power cable was also shown, and a number of special sections of cables relating to the war and in use by the United States signal corps.

JOHN W. BROOKS, of the Monadnock Block, as special agent in the territory, issued circulars as to the Syracuse headlights for cars, the Crouse-Hinds Electric Company's switches, switchboards, panel boards, etc., and the "Syracuse China" drop sockets of Pass & Seymour, the well known porcelain manufacturers. Crouse-Hinds switches range from 10 amps. to 5000 amps.

THE STANDARD PAINT COMPANY, of New York, and most other big cities in the world, had a pretty booth in which were grouped artistically cans and packages of the famous P. & B. compounds and other specialties so familiar in various departments of railway insulation. These were set off by framed diplomas of merit, etc. The company was represented by F. S. De Ronde, general manager at New York; J. C. Shainwald, manager at Chicago; O. K. Heppes, of the Chicago office, and F. S. Howard, traveling agent. In addition to the distribution of literature, samples, etc., the company presented its friends a handsome and costly leather pocketbook, which, it is needless to say, was eagerly sought after. It is whispered that there were some in white leather for the ladies.

THE SPEER CARBON COMPANY, of St. Marys, Pa., was represented by John S. Speer and A. Kaul, Jr., and made a promising debut at a street railway convention, although it was by no means Mr. Speer's first appearance at such scenes. The company had a display of its railway carbon specialties in the Morris space and exhibited electric light carbons in addition to carbon brushes. The company distributed considerable numbers of a new and handsome catalogue price list of fifty-two pages, devoted to dynamo and motor brushes for all classes of work, and of all the standard makes on the market. The data in this useful catalogue are most minute as to sizes and the type of brush required, price, etc. Besides this, Messrs. Speer and Kaul gave away with liberal hand leather cigar cases and purses.

HAROLD P. BROWN, of New York, with the co-operation of Lieutenant F. B. Badt, of Chicago, made, on the main aisle, an effective exhibit of his solid copper bond, emphasizing this evolution of the appliance in sharp contrast with the other extreme as embodied in the flexible types. This interesting Brown bond consists essentially of a piece of rolled electrolytic copper, 3 ins. long, about 1½ ins. wide and ⅛ in. thick, although these dimensions may be varied. At each end is a cup-shaped projection, and inside the concavity is a piece of sheet steel supporting a pair of steel springs. The steel is used to keep the springs from wearing the copper. The pieces are all held together by a small iron strap until the bond is applied, when the sharp web on the inside of the spring cuts it away and enters the angle plate, thus aiding the conductivity of the bond, which is amalgamated to prevent rusting, and which has its contact surfaces covered with plastic alloy. Naturally, this ingenious novelty attracted much attention. A case contained examples of other types to show freaks and peculiarities of wear; while the Brown bond was shown on sections of rail, in place. In order to give an accurate idea of its value, Mr. Brown had a compact plant operating in his space, comprising a Zucker-Levett American Giant double armature generator giving 3000 amps. at 10 volts, driven by an Edison 20-kw. motor, with Ward-Leonard rheostats, and two very fine Weston instruments, one reading up to 2000 amps. and the other reading fractions of a volt down to .00001. The effect of the bond in estab-

lishing perfect electrical continuity of track was demonstrated to all comers in this way. The current was first put in series through a joint of 80-lb. T rail, with no bond and a joint of 70-lb. T rail, with a Brown solid copper bond on each side and angle plates loosely set up. The unbonded 80-lb. joint, with 2000 amps., showed a drop of 0.423 volts. Mr. Brown then amalgamated the top of the rails at the inner ends, and laid upon these amalgamated spots one of his No. 0000 bonds. The drop with 2000 amps. was then .018 volts. The drop of 1 in. of solid rail with same current was .00223 volts, showing bond was equal to about 8¼ ins. of rail in resistance. The drop on the 70-lb. rail joint with 2000 amps. was .01946 volts. With an extra bond laid on top of rail the drop with same current was .00762 volts; the drop of 1 in. of this rail, with same current, was .00286, showing the bond was equal in resistance to about 7 ins. of rail. This joint was set up with a small monkey-wrench. In actual work, Mr. Brown said, much better results would have been attained. Tests were also made in the same way with other makes of bonds. One showed .425 volts' drop, with 1000 amps. and .75 volts, with 2000 amps. The other showed respectively .22 volts and .37 volts' drop. Both heated to redness in the time required to make tests.

THE MORRIS ELECTRIC COMPANY, of New York City, was represented by Elmer P. Morris, treasurer; G. C. Ewing and Mr. Delano. The exhibit was extensive and remarkably varied, covering the whole range of electric railway supplies. It was grouped along a considerable stretch of the left aisle and was tastefully arranged and decorated with plants, foliage and bunting. At one end was an annex known as the ball grounds and fair grounds, according to the selection of the visitor, the entrance to this abode of hospitality illustrating over its portal the operation of the Hunter illuminated sign. Conspicuous among the exhibits was the Morris rail bond, to which attention was directed by a large sign and by a model 4 ft. long. The rear wall of the exhibit on which these were placed, showed also an assortment of the car straps of J. E. Rhoades & Sons, the Anderson line material, and the Garton lightning arresters. There was also displayed a very interesting collection of complete and dissected bearings for various sizes of journals made by the Spiral Journal Bearing Company, of St. Louis. At the front of the booth were shown by well selected samples, the poles, brackets and line material of the Electric Railway Equipment Company, 25-amp., 50-amp. and 60-amp. circuit breakers of the General Equipment Company; the street track drill made by the Michigan Manufacturing Company; one, two and four duct Mason terra cotta conduits made by the Potomac Terra Cotta Company; Dale Manufacturing Company's shades and socketless clusters; the sand boxes of Louis Fink, of Boston, and the Bock triple-glaze insulators of Thomas & Company, of East Liverpool, Ohio. The samples of Speer carbons shown are referred to in another item. Other features of the exhibit were the track cleaner of Van Dorn & Dutton, and the neat work in detail and complete of H. P. Cameron's assembled commutators. The Munder incandescent lamp was shown and a clever point was made by large pictures of the Brooklyn Bridge with its huge "Welcome Dewey" sign built up from 8000 Munder lamps.

THE CRANE COMPANY, of Chicago, although making nearly everything used in power plants, found that the limited space at its disposal prevented an exhibit of a complete line and only such articles were shown as it was thought would prove interesting to users of high pressure steam. The exhibit comprised an assortment of extra heavy gate valves for 250 lbs. steam pressure, showing the No. 8-E with inside bronze screw, the No. 10-E with outside steel screw and yoke and the No. 11-E with outside steel screw, yoke and by-pass. High pressure globe and angle valves, Nos. 20-E and 21-E, pop safety valves, automatic relief valves, flanged fittings, large pipe, flanged to show style of workmanship, brass valves and pipe threading tools. Sections of the wedges and hard metal seats of the gate valves were also shown to illustrate the method of construction. The exhibit was in charge of J. A. Minwegen.

J. P. SJOBERG & COMPANY, manufacturers of street car woodwork, New York, were represented by J. P. Sjoberg and W. J. Walker.

THE SPRAGUE ELEVATOR COMPANY, of New York, through C. A. Benton, called attention to the ingenious system worked out by F. J. Sprague for handling trolley cars in car houses by electric elevators, so that better storage can be obtained in a tall building with facilities for easy release for service. The proposed scheme of operation was designed for the following conditions, viz.: that the elevator should be operated with load only, which load need not necessarily be the maximum one, but should consist of, at least, an empty trolley car on the platform. These conditions are specified for economical operating reasons only, otherwise the net hoisting duty imposed upon the machine would be too great to allow the economical operation. The elevator system is in equilibrium when the platform is carrying its maximum load, and under these conditions the highest economical rate of operation is attained, for the reason that the only power consumed is that which is necessary to overcome the friction in the various parts of the system. By employing the system as above described, it is evident that with proper changes in the weight of the drum and car counterweight, any conditions of average load can be successfully met with this type of machine. The capacity of the hoisting machine itself, as shown in blue print and as designed and built for the Central London Railway, is 10,000 lbs. net on the hoisting drum at a speed of 200 ft. a minute. By the multiple sheave arrangement proposed, the machine is amply able to meet the duty required at a speed of 100 ft. per minute. The control used in connection with this machine is entirely electrical and includes all the safeguards in the way of automatic upper and lower limits of car travel, slack cable device and speed regulator. These devices, in connection with the form of controlling switch used on the car itself, render the system safe under all conditions. In addition to Mr. Benton, the Sprague interests were represented by Mr. Shepard on behalf of the multiple-unit system, and Mr. Kittle, of Chicago, in behalf of its generators and motors.

THE IRONSIDES COMPANY, of Columbus, Ohio, had a very attractively arranged exhibit, representing a collection of barrels marked with the names of its respective specialties. The sign "Lubrication Without Oil" attracted attention. The specialties of this company comprised materials for preservation and protection of wire ropes and fibre ropes, the lubrication of gearing, paints for metallic surfaces, etc. For the electric cars the company is placing special stress on its lubricant for motor gearing, and to demonstrate the merits of this material, had on exhibition a pair of stand-

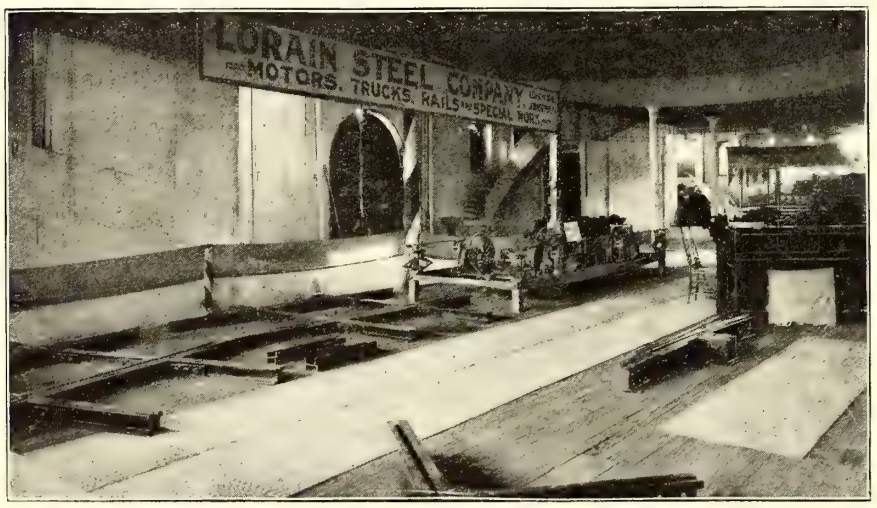

EXHIBIT OF THE LORAIN STEEL CO.

EXHIBIT OF GARTON LIGHTNING ARRESTERS

ard motor gears which had been treated with this lubricant gear shield. Large number of orders were reported as having been placed during the convention. This material has not only been shipped to all sections of this country, but orders have been taken from many distant parts of the world.

THE CHICAGO MICA COMPANY, of Chicago, had a neat pink and green booth in the gallery in charge of W. F. Hatch, secretary, and W. A. Snider. This is a new company in the mica business, but reports that it has already established a good trade. Its special mica composition is known as "Micabonds."

W. R. MASON, St. Louis, representative of the Siemens-Halske Company, of America, and who never misses a convention, was on hand in the interests of his company.

THE W. H. SILLS MICA COMPANY, of Chicago, had a wall space where it showed, on a board, a handsome collection of its products. C. B. Wisner, president, gave away an interesting card which showed graphically the years in which financial panics have and will occur again. It, therefore, warns the holder when to make and not to make investments.

THE UNITED STATES ROCKING GRATE BAR COMPANY, of Chicago, had one of its rocking grate bars on exhibition and gave away a "Lecture on Combustion," by his Satanic Majesty. John J. Moroney and J. F. Thompson were in charge.

MAYER & ENGLUND, of Philadelphia, were represented by A. H. Englund.

THE HALE & KILBURN MANUFACTURING COMPANY, of Philadelphia, displayed in its exhibit several styles of the popular "walkover" seats. The No. 80-¾ seat, made with movable foot rail, attracted much attention, every one heartily approving this new feature. The grip handle, which is applied to several seats in their exhibit, also received favorable comment. Some reversible seats were also exhibited as well as sample of spring edge longitudinal seating. The Hale & Kilburn patent steel top spring work was praised by every one, and many referred to it as the best spring construction upon the market. H. T. Bigelow, Western representative of the company, had charge of the exhibit.

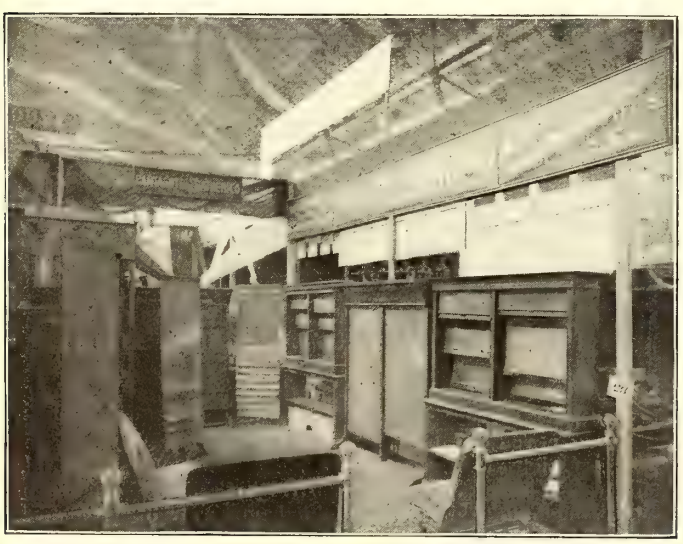
THE W. R. GARTON COMPANY, of Chicago, represented many well known manufactures. The new circuit breakers of the General Equipment Company, of Camden, N. J., served to attract general and very satisfactory attention, while the Eureka flexible copper rail-bond, the latest type, was displayed in a most becoming manner. The bond is made by the Eureka Tempered Copper Works, of North East, Pa. A line of its well known knife switches, copper and gauze brushes and segments, was also shown.

EXHIBITS OF CONSOLIDATED FENDERS, M'CARDELL WAGONS, MEAKER REGISTERS AND SIEGRIST LUBRICATING SYSTEM

The W. R. Garton Company also arranged an operative display of the Multiplex reflectors, arc and incandescent, a line of which is just being introduced by the Multiplex Reflector Company, of Cleveland, Ohio. This reflector is a decided departure in this line and was well received. The Partridge Carbon Company, of Sandusky, had an exhibit of its plumbago, as well as treated, special and regular carbon motor brushes. The Billings & Spencer Company, of Hartford, Conn., had a handsome display of its drop forged commutators bars. One of these bars weighed almost 50 lbs. The Keystone Electrical Instrument Company, of Philadelphia, had on display a magnificent board showing its various switchboard instruments, including ammeters, voltmeters for railway and arc light circuits; ground detectors, portable instruments, etc. A. O. Schoonmaker, of New York, exhibited some mammoth sheets of India and amber mica, and his mica discs were to be seen everywhere. The enclosed arc lamps of the Lea Manufacturing Company, of Elwood, Ind., made a decidedly favorable appearance. This company makes a full line of both d. c. and a. c. machinery. Johnson & Morton, of Ithaca, N. Y., had a series of photographs of their products on display. Samples of the Pitts-

burgh Steel Hollowware Company's pressed steel gongs were also shown, and had it not been for convention rulings, certainly would have made themselves heard. The Graphite Lubricating Company, of Bound Brook, had a pretty display board of its genuine graphite and bronze trolley wheel bushings. Enamalac and Armalac, the Massachusetts Chemical Company's specialties, along with samples of its various tapes and compounds were shown to advantage. Besides Mr. Garton and Mr. Lee, members of the W. R. Garton Company, Messrs. A. L. Short, of the Eureka

EXHIBIT OF DIAMOND BRAKE SHOES



Tempered Copper Company, and James Partridge, of the Partridge Carbon Company, were present to assist in the exhibit.

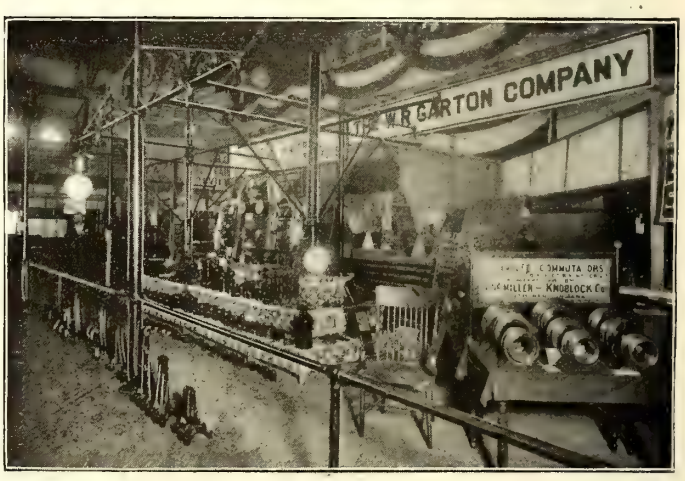
BERRY BROS., manufacturers of railway varnishes, Detroit, Mich., were represented by L. M. Combs, of St. Louis, who says he will never miss another street railway convention if in his power to be there.

J. B. PERRY, of Toronto, Ont., was in attendance in the interests of the McCollum Compound Friction Car Brake Company, of Toronto.

F. A. LAPHAM, of the Cleveland Frog & Crossing Company, Cleveland, was a constant attendant.

PATTERSON & GREENOUGH, of New York, were represented by Frank L. Crocker, their Chicago representative. This firm is selling agent for the Waterloo Woolen Manufacturing

THE PANTASOTE EXHIBIT



Company, of Waterloo, N. Y., and made a nice exhibit of uniform cloths, etc.

THE STIRLING BOILER was represented by B. M. Barr, of the New York office, and J. P. Snedden, chief engineer, of the Chicago office.

H. T. MERCUR, general agent of the Corning Brake Shoe, Corning, N. Y., was an active representative of this well known company.

THE ELECTRIC RAILWAY EQUIPMENT COMPANY, Cincinnati, Ohio, the well known manufacturer of street railway overhead line material and steel and iron tubular poles and brackets, had in charge of W. J. McCallum a display which was one of the most elaborate at the convention. A characteristic iron railing surrounded the space and a generous array of pole and bracket construction served to give the visitors at the convention an idea of the excellency of this line of the company's work. Across one side of the exhibit was arranged a number of 30-ft. steel tubular poles, showing various sections, diameters and lengths. Through the center of the space was arranged an oblong pedestal, supported at one end by a center pole, showing an arrangement for double track construction, and at the other by a pole upon which were mounted several of the companies numerous brackets. Upon this pedestal were shown in excellent shape the various items that go to make up one of the most complete lines of overhead material made in the world. A thorough demonstration of the company's type of figure 8 material, in all its forms, as well as that of the West End type, was most successfully given. Malleable iron pole fittings, cross arms, clamps, etc., were presented galore. Ornamental bases and trimmings for poles were also shown; in fact, all the poles erected were trimmed throughout in the latest approved fashion. One of the principal features in this display was the demonstration of the Equipment Company's method of tubular pole construction, which is meeting with so much favor to-day.

THE HUBBARD BRAKE COMPANY, of Chester, Pa., was represented by George E. Pratt, the vice-president of the com-

VIEW ON ONE OF THE AISLES

pany. The company made no exhibit, but Mr. Pratt distributed pamphlets that briefly explained the working of the company's new solenoid electric brake and secured several trial orders during his stay at the convention.

THE BINGHAMTON OIL REFINING COMPANY, of Binghamton, N. Y., was represented by A. S. Dexter, manager of the Chicago office.

A. C. VOSBURG represented the New Process Rawhide Company, at Syracuse, N. Y. Mr. Vosburg reports that the company's new plant is running to its fullest capacity and that the demand for its rawhide pinions has extended to every part of the world where gearing is used.

THE HARRINGTON RAIL BONDING COMPANY, of New York, was represented by S. H. Harrington, the general manager of the company.

THE G. C. KUHLMAN COMPANY, street car builders at Cleveland, Ohio, was represented by G. C. Kuhlman.

THE R. BLISS MANUFACTURING COMPANY, of Pawtucket, R. I., had on exhibition full-size working models of its well known Wood platform gates, of which from 45,000 to 50,000 are now in use on the street, steam and elevated railways of the United States. A working model was also shown of a new folding gate for double-door and vestibule cars. This gate, when closed, is folded back against the car body, fitting very well into the narrow panel found on double-door cars. Another novelty shown was the Crone pneumatic gate for use on air power cars or cars using air for brakes. This has been in use for two years and gives good results. The exhibit was in charge of N. H. Colwell, the general manager of the company.

JAMES L. HOWARD & COMPANY, Hartford, Conn., were represented by F. K. Dorrance, of the Western Union Building, Chicago. Models were shown of the Agard vestibule sliding door. This door is used successfully on the cars of the Hartford Street Railway and other Eastern roads, and is considered a very decided improvement over hinged doors.

F. H. NEWCOMB, of New York, manufacturer of uniform caps, made an interesting exhibit, showing samples of uniform caps as supplied to various companies throughout the United States.

THE CROUSE-HINDS ELECTRIC COMPANY, of Syracuse, manufacturer of the Syracuse changeable electric headlight, was disappointed in not getting its goods to the convention in time to make an exhibit. The company was represented, however, by its Chicago representative, John W. Brooks. The company reports that it has never been so busy since its organization. The "Syracuse Changeable" has become the standard headlight on a large number of roads throughout the United States, and is generally regarded as not only the highest type of headlight manufactured, but the most economical one to purchase, as one light answers for either end of car or for either a summer or winter car.

THE HUNTER ILLUMINATED CAR SIGN COMPANY was represented by Lytle J. Hunter, the president of the company, and made an exhibit in connection with the Morris Electric Company, the Eastern agent for the company. The company showed

EXHIBIT OF THE DEARBORN DRUG AND CHEMICAL WORKS

an illuminated car sign with over thirty changes and arranged to be easily operated by the motorman.

EDWARD ROBINSON, New York, sole proprietor and manufacturer of the Wells light, was an early arrival at the convention. The Wells light is known to practically every steam and street railway for use in night construction and repair work.

THE VULCANUS FORGING COMPANY, of Cleveland, Ohio, was represented by Alfred G. Hathaway, who is well known in the street railway field as the builder of the Hathaway transfer table.

P. F. LEACH was present at the convention, representing Leach & Simpson, of Chicago, selling agents for The Bass Foundry & Machine Company, of Fort Wayne, Ind., builders of engines and boilers, and manufacturers of car wheels and railway castings.

THE ADAMS-BAGNALL ELECTRIC COMPANY, of Cleveland, was represented by E. J. Bagnall.

THE JEWETT CAR COMPANY, of Jewett, Ohio, was disappointed at not receiving its shipment for exhibition. A. H. Sisson, manager; C. E. Krebs, secretary, and N. Paulson, superintendent, were in attendance.

THE ST. LOUIS CAR WHEEL COMPANY, of St. Louis, was represented by A. A. Hilton, sales agent for the company.

SALVATOR POTIS, formerly chief engineer of the North and West Chicago Street Railway Companies, was a visitor at the convention.

THE AMERICAN CAR & FOUNDRY COMPANY, whose general offices are now in St. Louis, with manufacturing plants located at various points, both East and West, had a very practical exhibit of street car wheels. The exhibit was in charge of Scott H. Blewett, of the home office. A feature of the wheel exhibit was the display of finished wheels, with parts broken from their rims in such a way as to show the strength of the metal used in the rims, hubs and spokes, and the depth of the chill. The sample wheels shown included plate wheels for interurban service, plate wheels for ordinary city use, and a new style of key seat designed to save the strength of the axle. The display was made under the joint auspices of the Missouri Car & Foundry Company, the Wells

NEW M'GUIRE SWEEPERS

& French Company and the Terre Haute Car & Manufacturing Company, as the output of all of these concerns is now controlled by the American Car & Foundry Company.

THE AMERICAN RAILWAY SUPPLY COMPANY, of New York, maker of badges, had on exhibition a very handsome sample board of conductors' and motormen's badges in bronze, nickel and aluminum finish.

THE STANDARD UNDERGROUND CABLE COMPANY, of Pittsburgh, was represented by its Western sales manager, J. R. Wiley. The full line of samples usually shown at ex-

TAUNTON NOSE AND SHARE PLOWS

hibitions of this kind is now at the Export Exposition in Philadelphia, and on this account Mr. Wiley simply distributed the company's literature and "took orders." The Standard Company's manufacturing capacity is now so heavily taxed that it is building a new factory at San Francisco, and another in the East.

THE PROTECTED RAIL BOND COMPANY was very ably represented by J. M. Atkinson, Chicago, representing the Western territory, and A. H. Englund, of Mayer & Englund, Philadelphia, Eastern representative.

THE GARL ELECTRIC COMPANY, of Akron, Ohio, had an attractive booth, in which were shown the telephones manufactured by this company for railway work. In the branch of car

dispatching by telephonic communication, the company has made a specialty and its system is employed on a large number of roads. Mr. Garl was present in person and explained the method of operation to the visiting delegates.

THE PANTASOTE COMPANY, of New York, was represented by John M. High, the general agent, and H. M. Grier, the Western agent of the company. The display of car curtains for both open and closed cars, as well as curtains and upholstering material, was very handsome. Some especially striking effects are obtained by the use of curtain material wih silk finish. Pantasote curtains were shown on a sample car made by the St. Louis Car Company for the Chicago City Railway Company. Pantasote as applied to other products, such as sportsman's outfits, caddy bags, etc., also formed a part of the exhibit.

THE MILWAUKEE RAIL JOINT & WELDING COMPANY, of Milwaukee, had an exhibit at Tattersall's consisting of a variety of rail sections showing the actual condition and appearance of the cast joints employed in its system. The exhibit was carefully examined by many delegates who universally commended the system, especially the feature by which the joints can be cast without removing ties. In addition to completed joints, the company showed the steel jackets used as molds. E. M. McVicker, manager, and H. L. Prather, of Cleveland, Eastern agent, were present.

J. A. RUTHERFORD was at the convention with an attractive exhibit of samples of wire and cable for street railway purposes, as manufactured by the Pittsburgh Reduction Company, of Pittsburgh, Pa.

A. M. KITTRIDGE, manager of the Barney & Smith Car Company, Dayton, Ohio, made a hurried visit to the convention.

THE PECKHAM MOTOR TRUCK & WHEEL COMPANY, of New York and Kingston, did not consider it necessary to make as elaborate an exhibit as in former years, partly because its trucks have been employed so extensively in Chicago that practically all types can be seen, from the single trucks used under surface cars, to the heaviest double trucks employed on the South Side Elevated cars, and partly because the truck has been so widely adopted elsewhere that it can now be seen in operation in practically every large city in this country and abroad. The company had on exhibition, however, two of its latest type of truck. the 14-B3, described in the last issue. These trucks were equipped with motors, were examined with a great deal of interest by the delegates in attendance and their merits were explained by E. G. Long, J. A. Hanna and W. H. Gray, who represented the company. Edgar Peckham, the well known president of the company, was not in attendance. In addition, the company had one of its "Metropolitan Special" trucks in the exhibit of the Westinghouse Company.

E. A. and HIRAM B. CURTIS, of the Chicago Truck Company, were there.

THE BALTIMORE CAR WHEEL COMPANY, of Baltimore, Md., was represented by J. Paul Baker, secretary of the company, and exhibited one of the Lord Baltimore maximum traction trucks. This style of truck met with many favorable comments and gave the impression of strength and durability. Mr. Baker stated that the company had received many orders for this type of truck, including one of good size from Baltimore.

THE EXHIBIT of the Griffin Wheel Company, of Chicago, was one of the most tasteful at the convention. The space was given up to showing samples of different sized wheels made by this company, and sections of wheels, exhibiting the character and depth of chill. The exhibit was in charge of C. K. Knickerbocker, who had many customers among the delegates, all of whom spoke in the highest terms of the service given by the Griffin wheels. An attractive feature of the exhibit was the unique railing surrounding the booth; it was made up largely of small half wheels which gave a most business like appearance to the space.

EXHIBIT OF THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO.

THE J. G. BRILL COMPANY, of Philadelphia, was represented by W. H. Heulings, Jr., and G. M. Haskell, of the company's New England office. The Brill Company made no regular exhibit, but had a parlor at the Auditorium, where were shown models of the company's trucks, as well as photographs of some of the latest styles of cars built by it. These headquarters were very popular, particularly in the evenings, and visitors were most hospitably welcomed.

THE ST. LOUIS CAR COMPANY, of St. Louis, made no exhibit, but was ably represented by George Kobusch, the president of the company; Charles Y. Flanders, Eastern agent, and Lytle J. Hunter, Cincinnati representative.

THE CLING SURFACE MANUFACTURING COMPANY had an exhibit which attracted much attention from those steam users who are employing belted plants, and while direct connection has made great advance during the past few years, there are still many power stations in which belts are employed, and a number of engineers remarked that their number might have been greater if the Cling Surface had been on the market for a longer period of time. This compound has been indorsed by the highest

authorities in steam engineering, and its merits were clearly demonstrated in a practical way at the Chicago Convention.

G. P. MAGANN AIR BRAKE COMPANY, of Detroit, was represented by W. D. Ray, the company's general manager, and expected to have on exhibition its storage system of air brakes applied to a Peckham truck. Unfortunately the apparatus did not arrive in time to be shown in the hall, but the advantages of the storage system of air brakes were explained by Mr. Ray, who pointed out the fact that no compressing machinery is required on the car and that the car mechanism is reduced to the greatest degree possible. The absence of compressing machinery includes, of course, the elimination of all noise, and possibility of accident to this part of brake mechanism. Although this system has been on the market for less than a year, the orders secured have been numerous and the company is now entering upon the second year of its existence with an enviable record.

THE ELECTRICAL INSTALLATION COMPANY, of Chicago, was well represented at the convention, those of the firm present being J. I. Case, president; F. H. Fitch, vice-president; J. A. Brett, general manager, and A. M. Hewes, secretary and treasurer. This company has made a remarkable record during the six and a half years it has been in business, having closed in that time 112 contracts for street railway and lighting work, which number will be materially increased before the end of 1899, by the addition of several other contracts, upon which the company is now figuring. During the past season, the company has completed work in Kansas City, Vicksburg, Miss.; Chicago, and many other cities. The company is prepared to entertain propositions for any kind of electrical construction in any section of the country.

W. E. DODDS, of the Allis Company, Milwaukee, and J. B. Allan, Chicago representative of the company, were in attendance.

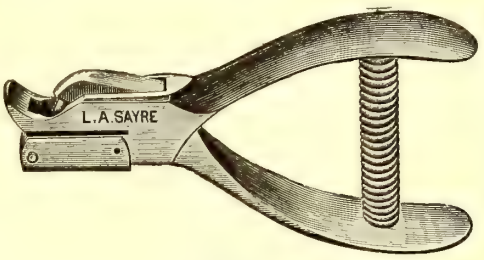
THE POWER TRACK CLEANER COMPANY, of Toronto, Can., exhibited at the convention, a track cleaner and digger, which is for use in both winter and summer. This is a contrivance for cleaning the track, so made that it passes over the uneven joints in the track and clears all obstructions before it. It is within control and easy operation of the motorman and can be placed upon the smallest platform without interfering with the brake or controller. Those roads which have used it have given the most flattering testimonials concerning its work. The company will shortly open up an office in the States, probably in Chicago.

THE KANSAS CITY CAR & FOUNDRY COMPANY, of Kansas City, Mo., showed various types of street car wheels. The company manufactures every type of wheel for car and engine service. The company was represented by F. W. and A. J. Fisher.

THE WESTERN ELECTRIC COMPANY, of Chicago, was represented at the convention by J. C. Cannon, Philip Rust and F. L. Swan. They had headquarters in booth 30, where they entertained friends of the company and distributed printed matter and souvenirs to visitors. The souvenir was a match-box having on one side an illustration of a petite arc lamp, and on the other, an illustration of a 16-in. fan motor. On both edges of the box were "Western Electric Company, Chicago-New York." The box was finished in silver and white celluloid.

JOHN T. McROY, inventor of the McRoy vitrified clay conduits, and who is owner of what is said to be the largest clay converting works in the world, was on the special New York Central Lake Shore train, bound for Chicago, and attended the convention. Mr. McRoy says that the entire output of his work is sold for two years to come.

THE AMERICAN CAR COMPANY, of St. Louis, was represented by William Sutton, president, and E. J. Lawless, of New York.



GEORGE E. SHINKLE and A. WHITING WATRISS, Chicago representatives of Charles A. Schieren & Company, were active at Tattersall's, though they did not make an exhibit.

THE HAM SAND BOX COMPANY, of Troy, N. Y., was present, as usual, and the exhibit of its box attracted much attention. The construction of this box is so well understood that no particulars are required here. It need only be said that the fact that the box has no valves and few parts, and is warranted not to rust, leak, waste sand and draw moisture, made the exhibit an interesting one. The box is used extensively in Chicago.

E. J. BAGNALL, of the Adams-Bagnall Company, was in Chicago during two days of the convention, and visited the exhibit at Tattersall's. The Adams-Bagnall Company is just putting upon the market a new arc lamp, which it believes is the first satisfactory lamp of this kind yet put out.

THOMAS AHEARN, of Ottawa, one of the best known engineers and contractors, of Canada, was present at the Chicago convention on Wednesday and Thursday, and will come to New York before returning home.

L. A. SAYRE & COMPANY, makers of punches, Newark, N. J., were represented by Mr. Sayre, who showed their No. 428 punch, which is especially adapted to street railway service and which is in use on a large number of railways. Mr. Sayre presented to the street railway people present one of the most unique and handsome souvenirs that was shown. It consisted of one of their No. 428 punches in miniature size and a handsome deck of playing cards, both enclosed in a handsome case. An illustration of this punch is shown herewith.

MINIATURE PUNCH

Exhibit of the Christensen Engineering Company

The Christensen Engineering Company's exhibit at the convention consisted of—

First.—A complete air-brake instruction stand showing the operation of the independent motor compressor air brake. This instruction equipment is more particularly described in the Christensen Engineering Company's catalogue B, page 37.

Second.—An installation of a five-car equipment, with automatic air brakes complete and in operation, with air gages showing the pressure in each cylinder on application of the brakes. The triple valves are the Christensen quick-acting type, suitable for steam railway practice. This is the device on which the Court of Appeals for the District of Columbia recently rendered a favorable decision. The engineers' valves in this five-car equipment are of the automatic train pipe feed type, giving excess pressure in the main reservoir.

Third.—An exhibit of a special high-pressure air compressor made for the United States torpedo service. It is designed for 1500 lbs. per square inch, and is capable of compressing up to 2500 lbs. The storage tanks for this compressor are tested to a pressure of 4000 lbs. per square inch, and are made in one piece of steel on the cold-drawn process.

Fourth.—A complete portable air-compressing apparatus for use around car shops and power-houses. It consists of an air compressor of 11 cu. ft. of free air capacity per minute, together with automatic cut-out switch, fuse, piping, etc. It weighs about 800 lbs., and is mounted on a truck, so as to be wheeled about wherever it is desired to use the compressed air.

Fifth.—A portable air-compressing apparatus, built up in substantially the same manner as the one above mentioned with the exception that it is a much larger compressor, being of a capacity of 50 cu. ft. of free air per minute. Its weight complete is about 1600 lbs.

Sixth.—An air hoist of the standard type, made by the Christensen Engineering Company, having an automatically closing valve working in such a way that no air can enter into the hoist from the main reservoir, nor escape from the hoist to the atmosphere without the operator holding the valve open, either for admission or exhaust.

The company brought a new catalogue to the convention, and among the many courtesies bestowed upon the delegates was the presentation by the company to each lady attending the banquet of a beautiful basket of flowers. The company was represented by S. W. Watkins, N. A. Christensen, A. Beveridge, and W. J. Richards, of the home office, and F. C. Randall, general Eastern agent.

Exhibit of the Westinghouse Company

The most costly and elaborate exhibit made at the convention was that of the Westinghouse Electric & Manufacturing Company. The largest piece in the exhibit was a 500-kw. "engine type" railway generator complete—a beautiful machine in design and workmanship. The armature was placed on a platform apart from the fields, so that both could be examined to better advantage. There also appeared in the Westinghouse exhibit a 200-kw. rotary converter, equipped with starting motor, and a rail-

way station switchboard complete for three generators, six feeders and one load panel, together with two No. 68 500-volt railway motors, with auxiliary apparatus, mounted on a Peckham truck, two No. 49 500-volt railway motors, with auxiliary apparatus, mounted on a McGuire truck; one No. 70 railway motor complete, one No. 69 railway motor complete, one No. 56 railway motor complete, and several armatures partially wound, with commutator connected, so that all stages in the building of the armature could be observed, and a complete line of detail apparatus, including fuse boxes, lightning arresters, canopy switches, etc., used in street railway equipment.

The 500-kw. generator was one of three of the same size recently sold to the Monongahela Traction Company, of Pittsburgh, and the switchboard is also sold to the same company. The No. 68 and No. 69 motors are the latest types built by the Westinghouse Company, and in placing them on exhibition the company called attention to a number of new features of great importance. One of these is the increased current-carrying capacity of the field windings, by means of which an equal temperature rise in both field and armature is permitted, instead of, as has heretofore usually been the case, the passage of more current, in proportion, through the fields than through the armature. Another feature is found in the use of field poles, which are bolted to the yoke, instead of being cast in, as has been the practice for the last ten years with the Westinghouse and other companies. These new motors were originally built on an order from the Third Avenue Railroad Company, of New York City, and since then large orders have been placed by the Brooklyn Rapid Transit Company and others.

The company was represented at the convention by the following: William Bauder, J. M. Duncan, C. S. Cook, W. M. Probasco, F. McCoy, J. H. Reid, C. E. Skinner, N. W. Storer, F. S. Smith, of Pittsburgh, Pa.; W. W. Grant, of Ottawa; J. R. Gordon, of Atlanta; H. C. Marsh, of Cincinnati; R. S. Brown, of Boston; C. H. Bragg, of Philadelphia, and C. S. Powell, of Cleveland; W. S. Rugg, Irvin Dryer, C. W. Regester, Frederick Nelson, C. G. Burton, W. R. Pinkard, L. M. Harvey, T. A. Hall, T. P. Gaylord, and Ivor Hennings, of Chicago; T. Julian McGill, of Minneapolis; C. F. Medbury, of Detroit, and A. Hatet, of the Westinghouse Electric Company, of France.

New Type of Electric Brake

A new electric brake, in which the motors are used as generators, has been placed on the market by the Hubbard Brake Company, of Chester, Pa. The brake consists of a large solenoidal magnet, to the plunger of which the brake levers are connected without interfering with the hand brake. The latter is left intact and ready for use. The solenoid is actuated by changing the motor terminals so that they will act as generators while the car is in motion, and these connections are made by a movement of the brake controller. The amount of current taken from the motors is about 25 amps. maximum, and the braking effect is automatically reduced as the speed of the car decreases, so that the greatest braking efficiency is obtained, while the possibility of sliding the wheels is prevented. The latter fact also eliminates trouble from flattening wheels. In case of accident to the motors the line current can be used to set the brake, but ordinarily the motor current is used.

In the system two brake controllers are employed, one on either platform. They are of about one-third the size of the car controllers, of which they are independent, except that if the brakes should be applied while the car controller-handle is on the "on" position, the connection between the motors and the line current is broken.

The general manager of the company is George E. Pratt, well known in street railway circles.

Resistance Tests in Chicago

The Chicago Edison Company has recently been making some interesting tests of resistance under different conditions of working contact. Readings were taken upon a Weston milli-voltmeter reading .0002 volts per degree. The first test was taken across the joint of an Edison tube through extension strips with contacts bolted. The average current was 1800 amps. and the ten readings varied from .00550 to .00544 volts. The average was .005466. The same joint was tested later with contacts amalgamated and treated with the Edison-Brown plastic alloy. The current used was 1740 amps. and the average drop was .003564.

Similar tests were made on a tube in the Edison Company's subway, near the Chicago River, with ordinary bolted contact and 1800 amps. The drop in voltage, with 1800 amps., averaged .004619. For the same joint, with contact amalgamated and treated with Edison-Brown plastic alloy, the average current being 1730 amps., the drop was .00321. Other tests were made, indicating about the same difference in resistance, due to the use of this device.

Cork as a Frictional Agent

The use of cork for frictional purposes in brake shoes by the Composite Brake Shoe Company, of Boston, is well known, and it has proved so satisfactory for this purpose that the company is extending its application to other industrial uses, notably to discs and friction clutches in machinery. Such discs are now being used on the friction clutches of heavy movable-bed reversible planers for reversing the travel or motion, and where the application of the clutch with cork inserts is made twenty-five or more times per minute. The action is found to be quick, but without gripping effect, due, without doubt, to the elasticity of the cork. Oil is freely used on the clutch without apparent detriment to the functions of the cork inserts.

The application of cork in brake-shoes is not confined to steam and street railway service, but is coming into general use on fire apparatus and heavy wagons and carriages, and is also being experimented with on horseless carriages. Another field which is attracting special attention just now is its application to rubber tires, for which it has manifest advantages.

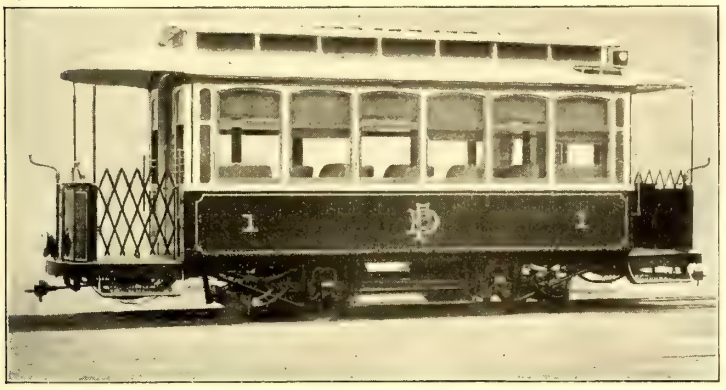
In the electric railway service in New England this brake-shoe is very largely used, and it is found that the elasticity of the cork overcomes the usual gripping effect and the flattening of wheels, and secures a smoother running of the cars. Wood plugs were formerly used, but cork is more tenacious, and, because of its elasticity and resilient nature, it will not become impregnated with iron particles from the wheels, or gather up sand and grit from the street, an important feature in connection with rubber tires.

Legal Decision

A decision in favor of the defendant has recently been rendered in the suit of the Consolidated Car Heating Company vs. the Palmer & Monson Street Railway Company. The suit was brought for the alleged infringement of patent No. 608,211, on improvements in electric heaters, and was defended by the Gold Car Heating Company, whose heaters were being used by the street railway company. The decision just rendered declares that these Gold heaters are not an infringement of this patent.

The Largest Rope Cable in the World

What is said to be the largest rope cable in the world is in use on the Glasgow district subway, and was manufactured by D. H. & G. Haggie, of the Wearmouth Patent Rope Works, Sunderland. Its weight is about 55 tons. The last cable removed from this cable road was also manufactured by the Messrs. Haggie, after a life of 14½ months. The previous best record was 10½ months. In other words, the rope just removed ran 85,000 miles, while the previous best record was 61,000 miles. The success of this cable is largely due to the improved cable-making machinery specially erected by Messrs. Haggie. The process adopted by them consists in making the strands and closing the rope on one machine, thereby securing the greatest possible efficiency and a perfect mechanically constructed rope.

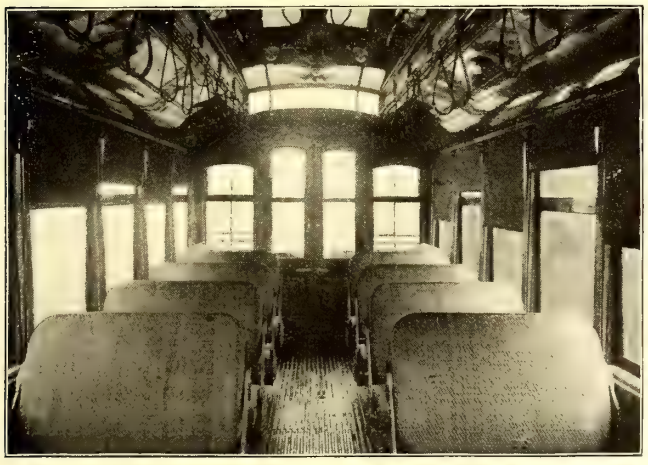


Enclosed Rheostats

The inclosed type of rheostat has become the favorite type for motor starters during the past few years. The resistance material is usually in the form of a reflex ribbon, which is embedded in sand, which sand is the filling material of a shallow box made entirely of iron or having one face of slate. A patent was issued Oct. 24, 1899, to H. Ward Leonard, which thoroughly covers the essential features of this form of rheostat box. The patent contains twenty-eight claims, and a typical claim reads as follows:

Claim 23. "In a resistance box, the combination of a box having two large parallel surfaces and a relatively narrow edge, one of the large surfaces being in the form of a cover, a resistance within the box arranged in steps or sections, terminals to which said steps or sections are connected, and a removable filling of mineral insulating material surrounding said resistance."

Street Car for Mexico



The car shown in the illustrations herewith is one of a large number recently built for the Ferro Carril del Districto of the City of Mexico. Externally these cars are very handsome, the large monogram and the straight panels setting off the gold of the lettering to admirable advantage. The length over the end panels is 18 ft. and the total width 8 ft. 2 ins. There are two platforms, each 4 ft. in length, making the length over the dashers 26 ft. The cars are mounted on Brill No. 21-E trucks, with 7-ft. wheel base, and equipped with two G. E.-1000 motors. There are eight reversible back seats, covered with woven cane, and four stationary back seats in the corners. Spring roller curtains are fitted to the windows, which are made to drop into the side of the car. The

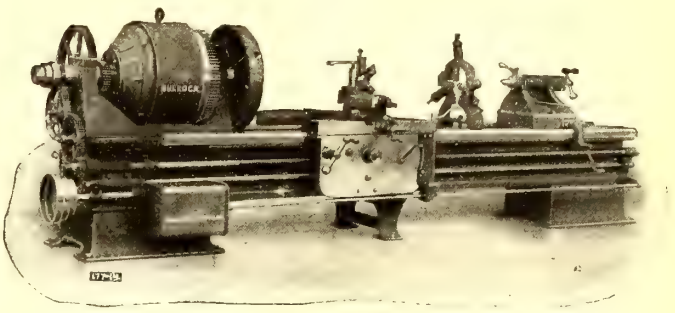
CAR FOR MEXICO

use of the cross seats was one of the reasons which brought the innovation of a straight-side car for street railway use. By a proper design and putting together of the side frame an exceedingly strong belt was obtained below the windows. The braces were cut into the belts, and posts secured with screws, and the sheathing was put on in the usual way and then glue-blocked afterward. Inside, the height from the floor to the belt rail is 2 ft. 3 ins., and from the bottom of the sill over the trolley-board about 9 ft.

As these cars have to be run in trains, there is a 15-in. opening in the center of each dasher. This has a sliding iron door, which goes in from the top, and when not in use is placed in grooves at

INTERIOR OF MEXICAN CAR

one side of the opening. Brill angle iron bumpers and Brill gates are fitted to the car. There are also two Brill sand-boxes and two Dedenda gongs. The trim is solid bronze throughout. The signal lamps are in a rather unusual position, being placed diagonally opposite each other on the roof landings. This is at the right-hand corner of the car going forward. It should be added that there are four spectacle glasses for each lamp, presenting four different colors—red, blue, green and yellow. The headlights are electric.



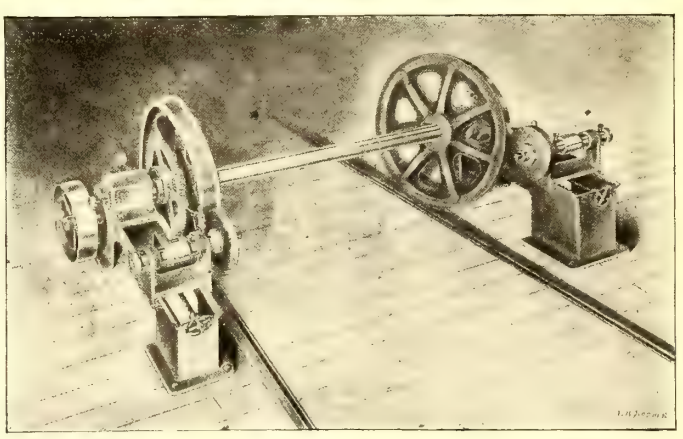
These cars were built on the Brill special system of construction, by which, after being completely finished "in the white," they are taken apart and shipped; one only of the whole number was completely painted in this country. From the view of the interior it will be seen that the car is a pleasant and agreeable one for the passenger, presenting the good features of elegance with light effect. The central chandelier is a combination of oil and electric lamp.

Electrically Driven Lathe

The practice of driving machine tools individually by electric motors, a method which is growing popular in many industrial establishments, seems particularly applicable to electric railway repair shops.

The illustration herewith shows a 28-in. swing-screw cutting engine lathe of this kind, driven by a Bullock, type "N" motor. As will be seen, the motor is placed directly on the spindle in the head stock, taking the place of the cone pulleys. The armature spider is built directly upon the hollow spindle of the lathe.

By means of a new system of variable speed control the motor is given a greater range of speed, without loss of torque, than is



ELECTRICALLY DRIVEN LATHE

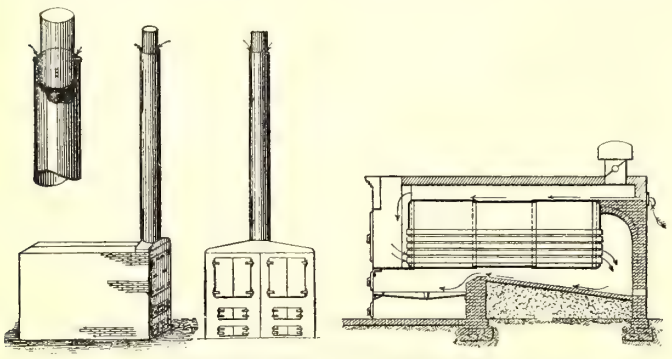
ordinarily given by the cone pulley, having sixteen speeds in either direction, including the back gear. The controller is placed upon the leg of the lathe directly under the head stock, and is operated by a spliced shaft running along the bed of the lathe, and a handle which travels with the carriage. The slowest speed is 60 r.p.m., and the highest about 250 r.p.m.

Car Wheel Grinder

Below is shown a new car wheel grinder designed to meet the demand for a substantial grinder at a low price. In this grinder the car wheels are rolled into bearings from the rear end, and the difference in the size of the axles is provided for by an adjustable

CAR WHEEL GRINDER

bushing operated by a screw. The car wheels are revolved at about 10 r.p.m. by a large gear and pinion, the latter being driven by a large pulley, which is belted to a small pulley on the countershaft. The large gear is held on the car wheel axle by a screw with adjustable bushings, and is put on before the car wheel is rolled into the machine.



The bearings for the emery wheel are two sleeves, each 7 in. long, with dust-proof collars. A sliding motion is obtained by a keyway cut on the outside of the sleeve bearings. An eccentric on the car wheel gear gives an automatic feed across the face of the car wheel. An emery wheel with a grooved face is used for grinding the car wheel flanges.

The advantages claimed for this grinder are that the adjustable bearings for the axle enable the operator to grind the wheel true

with the axle, even though the axle be worn or sprung, and that the weight of the car wheels can be much more easily supported by adjustable bearings when the strain is downward than on centers where the strain is outward as well as downward. The machines carry two 14 ins. x 1½ in. emery wheels. The grinder is manufactured by the Hampden Corundum Wheel Company of Brightwood, Springfield, Mass.

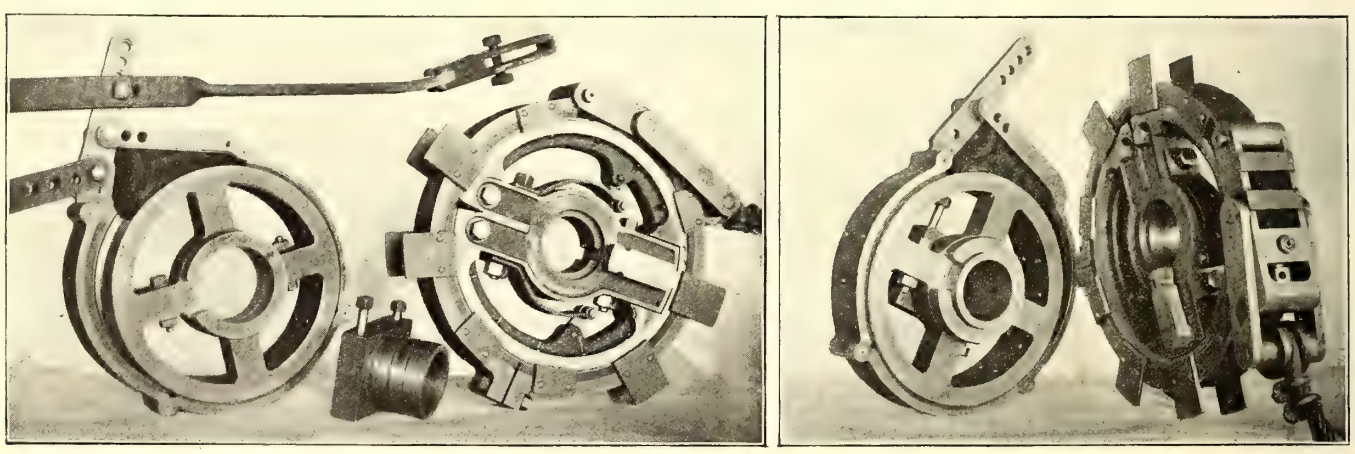
Schlicht Process of Combustion

Radical changes in methods of generating steam have been comparatively rare recently, as it is generally assumed that this branch of steam engineering has reached a stationary condition, so far as principles are concerned. For this reason the Schlicht process of combustion, which is certainly bold and novel in conception, has attracted much interest, especially from the fact that it has been employed in a number of manufacturing establishments with excellent results. Some of the prominent users of this

NEW PROCESS OF COMBUSTION

process are Fuchs & Lang Company, Brooklyn; Barber Asphalt Paving Company, Long Island City; the Fleischmann Distillery, Blissville, L. I.; Summit Silk Mills, Summit, N. J. The theory of the economy resulting from this process is the introduction of hot air, instead of cold air, into the combustion chamber. The method of this introduction, which constitutes the peculiarity of the system, is through the chimney. The process was thoroughly described by Mr. Schlicht in an address read before the Franklin Institute about a year ago, and in which he stated that when a tube of smaller diameter than the stack or chimney is inserted in the latter, the gases of combustion will escape through this tube, while a current of air will flow down outside of the tube within the flue, and thus reach the fire. It is not necessary to have the deflector the same height as the stack or, in fact, at all approaching the height of the stack; its insertion a short distance at the top of the stack is sufficient for the purpose.

The air in this passage down the stack is, of course, heated from the hot gases of combustion, so that when it reaches the fire the oxygen in it will readily ignite with the combustible elements in the fuel. With this method of working, of course, no air is admitted to the grate in the usual way. At first sight it would appear paradoxical to conceive a current of air flowing in the stack in a direction directly opposite to the gases of combustion, and it was upon this ground that the Government Patent Office originally rejected Mr. Schlicht's application, on the ground of inoperativeness. It was not until the inventor had made a demonstration in the basement of the Patent Office of the practicability of this invention, that its critics were convinced and then spoke in the highest terms of the invention.



Another interesting feature of the device is that separate chimneys to each furnace are not necessary for its successful use, but that each furnace will automatically take the quantity of air proportional to the combustion occurring therein. For instance, if twice the amount of fuel is being burned in one furnace than in another, both connected with the same stack, approximately twice the amount of air will automatically flow into the combustion chamber of that furnace. When used in furnaces burning soft coal the system materially reduces the amount of smoke injected into the air. The process is being placed on the market by the Schlicht Combustion Process Company, of New York. H. M. Thompson is vice-president and general manager of the company.

New Compound Friction Car Brake

For over a year tests and experiments with a new mechanical friction brake have been conducted on one of the large double truck cars of the Toronto Railway with such success that the company has acquired the right from the owners to equip its entire system with the new invention. Officials of the Buffalo Railway Company and of the Rochester Railway Company, who have visited Toronto to examine the device, have also been so impressed with its possibilities that both companies are planning to give it a trial in high speed service on their respective systems.

The brake is composed of two wheels 18 ins. in diameter, which, when fitted closely side by side on the car axle, occupy only 6 ins. of actual space. One of the wheels is expandable and is keyed firmly to the axle. The other wheel runs loosely on a sleeve on the axle. The wheels are connected togther by a loose rocker, or clutch, resting in opposite recesses in each wheel, causing both wheels to run together. A steel band lined with ½ in. of compressed paper encircles the periphery of each wheel, the band on the loose wheel being compressible while that on the keyed wheel is a rigid circle.

To operate the brake, the motorman, with suitable connection rods, gently compresses the band on the loose running wheel, retarding its motion, thereby reversing its pressure on the loose clutch, which in its turn, expands the other wheel within the rigid circular band. To this band the chain from the brake frame lever is attached, and thus the strain is put upon the brake shoes. It will be observed that unlike other friction car brakes, this not only depends on a compound, or double friction, but the wind of the chain is on an 18-in. circumference. A compression of only 1/16 of an inch on the loose wheel friction gives a great leverage on the main keyed wheel friction, makes the operator's work in the cab very easy, and gives him absolute control of his car.

COMPOUND FRICTION BRAKE

In stopping on grades, there is no back roll of the car, as the wind is so far from the axle, and although the most sudden emergency stop can be made, complete control over the operation of the brake is retained. As to the durability of the apparatus, it is stated that when the parts were examined after four months' steady running, making approximately 13,000 miles, and 196,000 stops, there was no perceptible wear. It will be noticed that the frictional pressure is most severe on the band linings, and these, it is said, were found had not worn down 0.01 in. in the four months.

The brake complete weighs about 175 lbs., and outside of slight regular lubricating, is said to require no personal attention whatever. J. B. Perry, director of the McCollum Company, Bedford Road, Toronto, which is manufacturing this brake, is about to form a company in the United States to place it on the market.

Important Presentation in New York

One of the principal points brought out in the discussion in Chicago upon Mr. Yerkes' paper was on the relations existing between employees and the managements of the transportation systems in different parts of the country. Apropos of this, one of the most striking events, showing the possibility of cordial relations existing between these two departments, occurred in New York last month, and its importance, judged in many ways, is so great, that more than a passing notice should be given it. It shows clearly that enlightened treatment, coupled with a thorough understanding of the needs and wishes of the men composing the operating force, and a willingness to comply with those wishes, when reasonable, is thoroughly appreciated by the men, and able to bring about a feeling in all departments that the welfare of each is being cared for by the other.

What makes the event, which of itself, we think, was unique, the more remarkable was its occurrence within a month after an attempted strike, during which every atttempt was made to create within the minds of the employees a feeling of distrust against the management, and their fidelity was assailed by all the demagogic arguments known to labor agitators, who had staked their reputations upon creating dissatisfaction against the company. It is needless to say that these efforts failed utterly, and the feeling of loyalty on the part of the road where the attempt was made was greater than ever before. The importance of this to the company can hardly be overestimated.

The event to which reference is made was the presentation of a loving cup and a set of testimonials to H. H. Vreeland, president of the Metropolitan Street Railway Company, by his employees. The presentation occurred at Carnegie Hall, Oct. 7, at the third annual meeting of the Metropolitan Street Railway Association of which Mr. Vreeland is president, and which is a mutual benefit organization of the employees of the Metropolitan Street Railway Company. The cup and testimonials were secured by a committee of the employees, entirely without the knowledge of the management, to whom the entire affair was a complete surprise. The contribution of each employee was limited in amount to 10 cents, and only those were allowed to contribute who had been with the company since before the attempted strike. In this way the offering became essentially a spontaneous tribute from those who were well acquainted with the personality and characteristics of the person whom they honored.

The cup, which is of silver, is illustrated herewith. The resolutions, which were very handsomely engrossed, bore the following words:

"The employees of the Metropolitan Street Railway Company, of the city of New York, being desirous of showing our high appreciation of your worth as an official, a man and a friend, offer you, Herbert H. Vreeland, president, our best wishes, and extend a vote of thanks for the interest taken in our welfare and the many kindnesses shown us in sickness and in health.

"That you and your family, through the grace of God, may enjoy many days in health and happiness is the prayer of the

"COMMITTEE FOR THE EMPLOYEES.

"October 7, 1899."

It is certain that no railway manager was ever a recipient of such a gift from all his employees as this, and it is one which is to be regarded as the most valuable of heirlooms.

The Metropolitan Street Railway Association, to which reference has been made, has been in existence for three years, during which time its membership has increased from 100 to 2630. Any employee of the Metropolitan Street Railway Company is eligible to membership, and it now includes most of the men employed by the company. Its main object is to give free medical attendance to its members, and $150 to their families in case of death, at an expense of 50 cents per capita per month. During the past two years the association has also established an excellent library for its members and their families, and if any member wishes a technical or engineering book for his own use or for that of some member of his family, and the work is not already in the library, it will be purchased upon request.

The meeting on Oct. 7 was preceded by an address by the president, Mr. Vreeland. Among other things he said: "At a time like this, when there is so much misleading talk concerning the evil effects to workingmen of large combinations of property, it is well for us to study our own case, and inquire what the effect of combination has been upon us. It is, of course, no part of our duty to here discuss the affairs of any other class than our own. We are railroad men, pure and simple, and we must regard movements and tendencies as they affect ourselves and our business.

"In probably no industry in the world has consolidation been more active in the last ten years than in railroads. In fact, railroad history of that period is one continuous record of 'combinations,' 'amalgamations,' 'mergings,' 'leasings,' or whatever term lawyers please to give to one and the same thing. In the nine years since 1890, 946 railroads, aggregating 63,000 miles, have been consolidated.

"None of the eloquent gentlemen whose prerogative it is to interest himself in every one else's business will claim that by reason of this consolidation the number of railroad employees in

CUP PRESENTED TO MR. VREELAND

the United States has been lessened or wages reduced. It is true, these consolidations have saved millions of dollars paid to high-class and ornamental officials, but so far as the operating and working forces are concerned (and with this we are most interested), the effect has been good.

"Within the period named, hours of labor have been lessened and wages increased, and in that time the number of railroad employees has grown, not alone by reason of extended mileage, but because even the so-called labor-saving improvements have called for more human help. I think it is safe to say that in every instance where an improved appliance has displaced one man, the demand for greater safety and improved facilities has created a demand for two.

"Nothing will bring this fact home to your minds more surely than a glance at the past and the present of the railroad systems on which you are employed. Do you find that the introduction of electricity as a motive power, instead of horses, has increased or diminished the working forces on the street railways which constitute the Metropolitan system? That system as now consolidated has a wage list ten times as great as that when its constituent properties were operated separately and by horses.

"Nor is this all, for with every increase in the volume of the list of paid operators, there has been a marked improvement in

the personnel and in the standard of the men. No one who knows the truth would, for instance, think of comparing the employees of this system with the rag-tag and bob-tail that constituted the working force of its constituent parts or companies when they were separately operated by horse power. The effect of consolidation upon us has been to elevate out of the slough of what is contemptuously called 'miscellaneous labor' between five and six thousand men into a distinct class, in which not only muscle but brain is demanded.

"New York City represents but a small portion of the mileage of street railways under electrical operation in the United States, and it is known to every one of you that any man who has been trained on this system, and whose character is good, can claim a place and obtain a standing by the very reason of his apprenticeship here, on any system anywhere in the world. So then, so far as we are concerned, we can look without any special discomfort at a combination whose results have been beneficial to us."

The immense audience which crowded the spacious hall were evidently in accord with Mr. Vreeland's remarks, judging from the hearty applause which followed. After the reading of the secretary's report a committee ascended the platform and made the presentation already described.

Mr. Vreeland acknowledged the gift in a few well-chosen words. A high-class vaudeville entertainment followed, and was thoroughly enjoyed by all present.

John M. Roach

The newly-elected president of the American Street Railway Association, John M. Roach, has had a long and most successful experience in electric railroading, and is generally looked upon by those acquainted with the street railway interests in this country as one of the most astute and successful managers of street railway properties in the United States. Like many other men of success, he has achieved his knowledge of and distinction in his chosen profession by beginning at the lower rungs of the ladder, and has successively shown his ability to master the prob-

JOHN M. ROACH

lems connected with railways operating with horse, cable and electric power, exhibiting in each a remarkable grasp upon the fundamental principles of the transportation and mechanical questions involved.

The subject of this sketch was born in Noble County, Jackson Township, Ohio, on Jan. 30, 1851. His ancestors came from Virginia and settled in the garrison on the Muskingon River, near Beverly. Mr. Roach left Ohio when eleven years of age, and went to Rockford, Ill., where he attended a high school for one year. After this he went to Corinne, Utah, and from that place to Helena, Montana, covering the entire range of the Rocky Mountains and spending three years in that section of the country prospecting for gold. On a "bucking" broncho he rode to Walla Walla, Washington Territory; Portland, Oregon; Oakland, and down into the lower part of California, around White Pigeon, Utah, and back to Helena, Montana.

After roving around the western part of the Continent for seven years, making and losing large sums of money, he returned to Rockford for a year, and settled in the city of Chicago on Oct. 7, 1872, entering the employ of the North Chicago Street Railroad Company as a conductor. He was an absolute stranger in the city, and had no friends nor acquaintances there. After serving the company as a conductor for four months he was taken into the office and made a cashier. From that position he served in all the intermediate positions, until in 1889 he was made general manager of the North Chicago Street Railroad Company, and in 1897 general manager of the West Chicago Street Railway Company, in both of which positions he remains in the companies which have succeeded to the control of these properties.

Mr. Roach married Miss Kate Lyon in 1872, at Rockford, Ill., and has one son, F. Lyon Roach, born in 1875. Mr. Roach is a member of the Union League Club, Marquette Club and Union Club, of Chicago, and a Knight Templar, Lincoln Park Commandery.

Personal

MR. SIEZO MISAKI, chief engineer of an interurban road connecting the city of Osaka, Japan, with the neighboring city of Kobe, was in Chicago during the convention and was much interested in the exhibits.

MR. W. S. DIMMOCK, general superintendent, and W. D. Tarkington, master mechanic, of the Omaha & Council Bluffs Railway & Bridge Company, attended the Chicago convention and renewed acquaintance with many of their old friends.

PROFESSOR ALEXANDER B. W. KENNEDY, one of the leading electrical engineers of London, has taken into partnership Mr. Bernard Maxwell Jenkin, who has been for some years past his principal assistant. The new firm will be very strong in engineering circles.

MR. W. J. COOKE, vice-president of the McGuire Manufacturing Company, was reported as ill at his home, and typhoid fever was feared. Mr. Cooke's many friends will sincerely hope that this danger may be averted and that he will soon be around again in his accustomed travels.

MR. F. S. DRAKE, formerly general manager of the Nassau Electric Railroad Company, of Brooklyn, and later master mechanic of the Brooklyn Rapid Transit Company, has now become connected with the St. Louis Transit Company as mechanical engineer, and attended the convention with friends. Mr. Drake has had a very valuable experience in electric railroading, dating from 1889 to 1890, when he was engineer in charge of construction of the first electric railway built in Buffalo. He later went to Pittsburgh and then to Brooklyn.

MR. F. L. FULLER, resigned, on Oct. 1, his position of general superintendent of the West Chicago Street Railway Company, to accept that of assistant to the president of the United Power & Transportation Company, of Philadelphia. This company, as is generally known, is a recent organization and controls and operates a large number of formerly independent railway and lighting companies in the neighborhood of Philadelphia and Wilmington, Del., also in other parts of Eastern Pennsylvania and in New Jersey. Among the companies included in this consolidation are the Wilmington City Railway Company, Wilmington City Electric Company, Wilmington & Chester Traction Company, Chester Traction Company, United Traction Company, of Reading; Reading & Womelsdorf Electric Railway Company, Holmesburg, Tacony & Frankford Electric Railway Company; Roxborough, Chestnut Hill & Norristown Railway Company; Trenton Street Railway Company, of Trenton, N. J.; Citizens' Electric Light & Power Company, of Delaware County; Delaware County & Philadelphia Electric Railway Company, the Lebanon Valley Street Railway Company, the Edison Electric & Illuminating Company, of Lebanon; Wilkesbarre & Wyoming

F. L. FULLER.

Valley Traction Company, Wilkesbarre, Dallas & Harvey's Lake Railway Company, and the Metropolitan Electric Company, of Reading.

To this company Mr. Fuller will bring a long experience in electric railroading, obtained in Chicago and elsewhere, which has given him a high reputation in this line of work. Mr. Fuller's connection with street railways dates from January, 1888, when he entered the service of the St. Paul City Railway Company, at which time he was appointed foreman of the Selby Avenue cable line, just then put in operation. In the following year the company decided to substitute electricity for horses on the greater part of its system, and at that time Mr. Fuller was appointed assistant superintendent. He remained with this company until the consolidation with the Minneapolis system in April of 1893, when he resigned and entered the service of the West Chicago Street Railway Company, of Chicago, as assistant superintendent. At this time the latter company had two cable lines in operation, but on the rest of the line horses were employed. In 1894 it was decided to change all the lines not operated by cable to electric, and Mr. Fuller was appointed superintendent. In 1895 he was made general superintendent and remained in that position until Oct. 1, this year, when he accepted the position mentioned above. Mr. Fuller will make his headquarters in Philadelphia.

MR. E. S. DIMMOCK has been made general manager of the Bay Cities (Mich.) Consolidated Railway Company. Mr. Dimmock has been engaged in steam railroading practically all his life until four years ago. He was in early life for seven years apprenticed in the mechanical department of a prominent road, and later became superintendent of motive power of the Union Stock Yards at Omaha, and superintendent of electric lighting of the stock yards. He is a practical engineer and machinist and will be a valuable acquisition to the Bay Cities Company. He is a brother to W. S. Dimmock, superintendent of the Omaha & Council Bluffs Railway & Bridge Company.

MR. H. F. J. PORTER, whose portrait is presented herewith, is well known through his connection with the general subject of hollow-forged open-hearth and nickel-steel shafts, and, in particular, upon their adaptability to street railway power plants. Mr. Porter has so long been an advocate of this type of forging for such service that his name has become closely associated with it in the development that has been witnessed in all sections of the United States. The earliest installations were made at Chicago, and to that city belongs the credit for much of the prestige now held by such shafts. Now that the hollow shaft has been firmly established in favor for use in large plants, it is hard to appreciate the immense labor involved in its introduction, for not only was it necessary to show its superiority over wrought-iron shafts which had been most generally in service in smaller plants up to that time, but Mr. Porter found a more or less firmly rooted antipathy to steel for this service, owing to the failures experienced in solid shafts made of low grade steels. Mr. Porter was formerly Chicago representative of Bethlehem Steel Company, but of recent years has been connected with the company's general sales department at South Bethlehem. He has not, however, confined himself to commercial life, but has delivered many lectures before technical institutions, principally on subjects connected with recent developments in high-class forging. His most recent work in this direction was an interesting talk on "The Position of Forging in the Arts," given Oct. 19, before the Political Economy Club at Chicago. Shafts of fluid-compressed open-hearth and nickel-steels, annealed and oil-tempered, have been adopted for practically all of the more recently planned large power stations in the East, notably those of the Metropolitan Street Railway Company, at Ninety-sixth Street, New York; the Third Avenue Railroad Company, of New York, and the Boston Elevated Railway Company, and it is safe to say that this practice will be closely followed in all future work involving the enormous units demanded by modern street railway practice.

H. F. J. PORTER.

MR. IRA A. McCORMACK has resigned his position as general superintendent of the Brooklyn Rapid Transit Railway Company to accept that of vice-president and managing director of the Syracuse Rapid Transit Railway Company. Mr. McCormack is known as one of the ablest managers in the country, and had been engaged in steam railroading for twenty years before going to Brooklyn. During this time his record was one of continual promotion. He filled each position in a most satisfactory manner, and was at one time located at Syracuse in charge of the interests of the West Shore Railroad Company. He moved to Brooklyn in June, 1895, to take charge of the eastern district of the Rapid Transit system, but was soon appointed general superintendent. As the Brooklyn Heights Company gained control of the various lines that now go to make up the system of the Rapid Transit Company they were placed in charge of Mr. McCormack, who soon had them running with the same evenness that has been brought about on the original lines of the company. Mr. McCormack's success has been attributed to two things, his just treatment of the employees, and his interest in behalf of the railroad company. He always felt that there were two duties of equal importance attached to his position, one being to the company and the other to the men. Mr. McCormack has the reputation among the rank and file of the company of treating his men with the greatest civility and this conduct he also inculcated among the minor officers of the road in their dealings with the men under them. During all the late difficulties with the men of the Rapid Transit road it was said that no harsh words were uttered against the superintendent. Mr. McCormack will occupy the position recently held by Mr. E. W. Moore, who resigned on account of large business interests elsewhere, except that Mr. McCormack will reside in Syracuse, which his immediate predecessor did not. Mr. C. Loomis Allen, present general manager of the Syracuse Rapid Transit Company, will continue in that position.

IRA A. McCORMACK.

AMONG THE MANUFACTURERS

THE GOLD STREET CAR HEATING COMPANY, of New York, has been awarded a contract for several hundred electric car heaters for the Glasgow tramways.

THE SIEGRIST LUBRICATOR COMPANY, of St. Louis, Mo., has recently published a new and tasteful catalogue, which they will be glad to send to any reader on application.

THE Q. & C. COMPANY, of Chicago, has announced that it now has exclusive control of the sale of Magnolia anti-friction metal to railroads, both steam and electric, of the United States, Canada and Mexico.

RUSSELL & COMPANY, of Massillon, Ohio, builders of the Russell single valve automatic cut-off engine, have recently issued a very tasteful catalogue containing general and detailed views of this engine, together with engravings showing the company's works.

HENRY L. PRATHER, of Cleveland, Ohio, has recently closed a contract with the Rochester Railway Company, of Rochester, N. Y., for the cast welding of several thousand joints on 4½-in., 6-in. and 9-in. rail. The welding system of the Milwaukee Rail Joint & Welding Company will be used.

THE J. G. BRILL COMPANY, of Philadelphia, has recently secured what is undoubtedly the largest order for trucks ever placed in a European country. It was awarded by the Electric Railway & Tramway Carriage Works, of Preston, Eng., and was for 700 trucks of the Brill 21-E and maximum traction types.

THE LYNN INCANDESCENT LAMP COMPANY, of Lynn, Mass., is manufacturing an incandescent lamp for street railway use, which embodies a number of important improvements. The lamp is anchored and cannot droop or be broken by the motion of the car. The lamps are made to burn in series on 500, 525, 560 and 600-volt circuits and are carefully selected so that they are uniform and long lived.

WILSON & COMPANY, of Brooklyn, N. Y., manufacturers of the Wilson trolley pole catcher, call attention to the fact that this device locks and holds the trolley pole fast the instant the trolley leaves the wire and does not draw it down below the trolley

wire in this contingency, as stated in the last issue. The company has a large number of letters from prominent railway companies, speaking in the highest terms of this device.

THE UNION BOILER TUBE CLEANER COMPANY, of Pittsburgh, Pa., has recently finished what is said to be the largest contract ever awarded for cleaning boilers, being twenty-two water tube boilers, containing an aggregate of 10 miles of 4-in. tubes—a task no other concern in the world has the equipment to accomplish. The company has also just shipped eight machines to England and Scotland. The initial machine for export was shipped just one year ago. One of the latter was a repeat of the first order.

THE LORAIN STEEL COMPANY, of Lorain, Ohio, has just published what is probably the most tasteful rail catalogue which has ever been published. The rail sections, which are usually illustrated by line sections are here represented by fine vignetted half-tone engravings, which adds much to the appearance of the book, while making the section shown no less convenient for measuring purposes. The rails are all reproduced full size, and there are some sixty-five of them, including both slot and service rails. The special work, crossings, joints, etc., are illustrated in the same way.

THE MANUFACTURING PLANT of the Vulcanas Forging Company, situated between Wason Street and Case Avenue, Cleveland, was entirely destroyed by fire Oct. 25. The fire was discovered by the watchman in making his rounds and had gained such headway by the time of the arrival of the fire apparatus that it was utterly impossible to save the building. Several freight cars which were standing in the rear of the building waiting to be loaded with forgings were also destroyed. The building was two stories high, and about 175 ft. long x 50 ft. wide. The loss is estimated at $30,000.

THE GENERAL INCANDESCENT ARC LIGHT COMPANY, of New York, is issuing circulars and price lists devoted to underground electrical apparatus. The Tailleur coupling boxes, service boxes, junction boxes and coupling joints and Ferguson's all copper safety catches are among the devices illustrated and described. The company has branch offices in all the large cities, and manufactures arc lamps, incandescent lamps, pure drawn copper switches, automatic clock and voltmeter switches, push button switches, fan motors, power motors, dynamos, switchboards, rheostats, underground materials, Wright's discount meter, etc.

THE TRADE PAPER ADVERTISING AGENCY, 150 Nassau Street, New York, has made a valuable addition to its force, in securing the services of Sam A. Elkington, who has been associated as advertising manager and advertising writer for the past ten years with a number of the leading trade journals of this country. There are few men more successful as an advertising expert, or one that is more familiar with technical journals than Mr. Elkington, and advertisers desirous of using trade papers will find his services of great assistance and value to them. Mr. Elkington will have charge of the Philadelphia office of the company.

THE CHRISTENSEN ENGINEERING COMPANY, of Milwaukee, has recently published a revised edition of its catalogue on the Christensen straight air brake apparatus, which gives not only views and complete information of the company's air brake, but a short synopsis of the progress of the company since it entered the field, and a discussion of the desirability of the use of straight over automatic air for electric railway service. It is interesting to note that the company has sold and delivered, during the past two years, nearly 1000 equipments, and that during that time the cost of maintenance for these equipments, computed from the sale of repair parts, has been only a fraction of 1 per cent.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, of Cincinnati, reports sales for the month of September involving sixty-one machines ranging in size from 3 kw. to 150 kw. Among the more important were fifteen engine-type generators for United States Army transports and ten 50-h.p. motors to operate at 200 r.p.m. for Messrs. Dick, Kerr & Company, of London, England. Several repeat orders were received, among them being the following: Maryland Steel Company, Baltimore, Md., third order; Consumers Park Brewery, Brooklyn, N. Y., third order; Atlas Cement Company, Northampton, Pa., fifth order; Missouri Lead & Zinc Company, Joplin, Mo., third order. When representative concerns, such as those named, find it to their advantage to continually add to their equipment of Bullock apparatus, it can mean but one thing, and that is, that the machines have given perfect satisfaction. A new bulletin, just issued by the company, describes type "N" motors. This is the first bulletin of the standard 6 ins. x 9 ins. size which has been issued. Those interested in electrical literature will appreciate this reduction in size, as it is more readily filed than the larger pamphlets. It may be had by addressing the company.

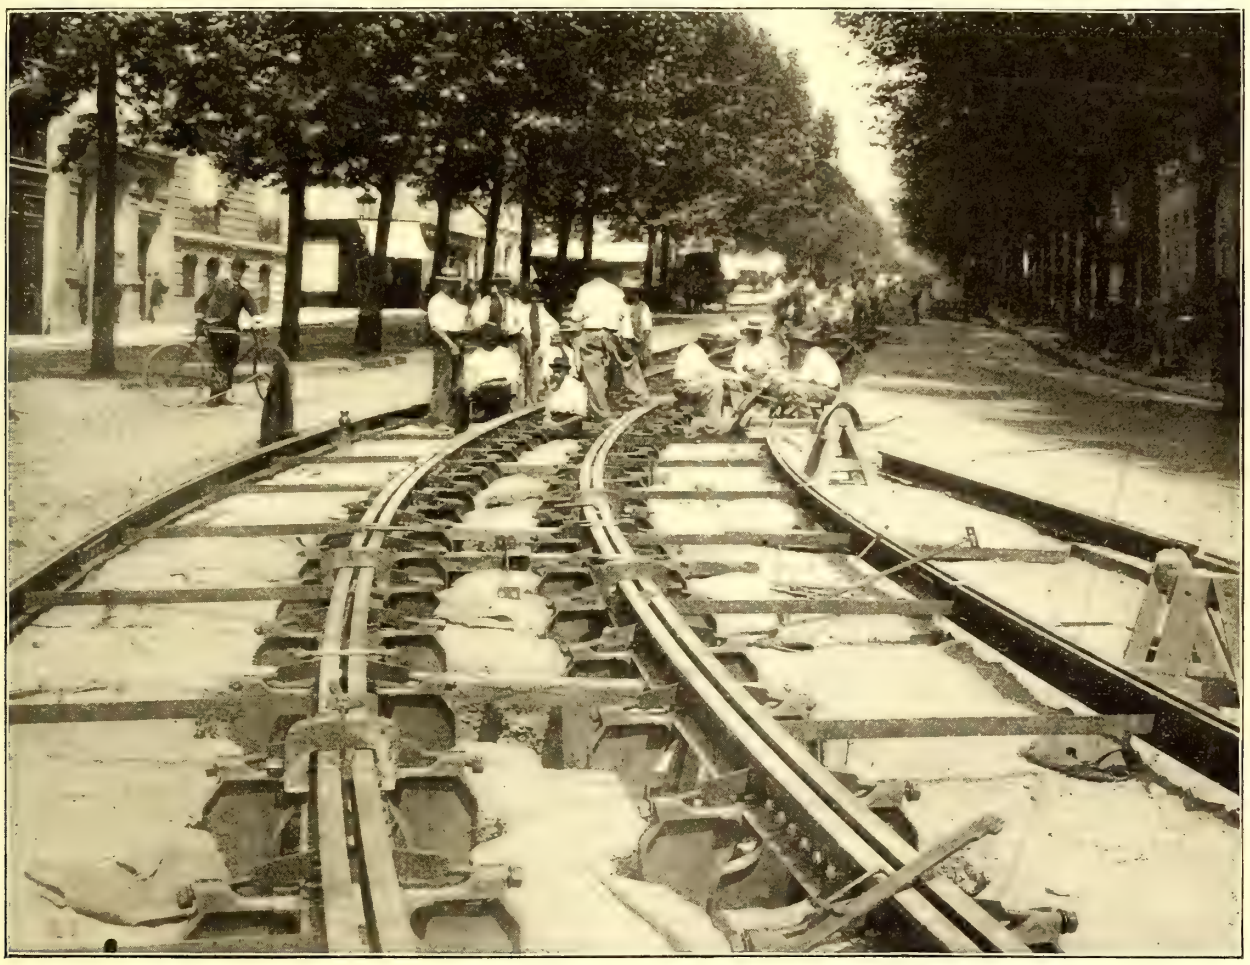
THE SIMPLEX ELECTRICAL COMPANY, of Boston, Mass., reports an active demand for "American" car heaters. In addition to many recent orders in New England and in the West, the company reports the sale of 600 heaters to the United Railways and Electric Companies of Baltimore, Md., this being the third successive order received from Baltimore within the past two years. The Simplex Company claims great durability for the "American" car heaters, and lays particular stress on the claim that their coils never rust out, as they use a special non-corrosive wire instead of steel alloy. While the wire is far more expensive than that commonly used, the results more than justify this practice—so the company claims. Since the Simplex Company announced the sale of enamel car heaters, there has been much interest evinced and sample equipments ordered by street railway companies. The peculiar advantages claimed for the enamel heater are, that owing to the resistance wires being completely imbedded in enamel uniformly distributed over cast iron plates, there is no possibility of injury or trouble developing by any meddling or carelessness on the part of passengers, and that the heaters being entirely waterproof offer no opportunities for trouble when the cars are cleaned, even if a hose is used. The company insists that this is the heater of the future.

THE RESULT of a series of tests carried on by Professor R. C. Carpenter, of Cornell University, upon "Cling Surface," a compound for belts manufactured by the Cling Surface Manufacturing Company, of Buffalo, was published in the May issue. Those whose attention was attracted to that article will be interested in a letter which Professor Carpenter sent under date of Oct. 7, to the same company. In this he says: "Later tests of the use of Cling Surface on belting substantiate in every particular the statements made in my report of April 17. They also indicate higher efficiency of transmission and less loss of power in the case of belts treated with Cling Surface than in the case of belts not so treated, when working under the conditions prevailing at the time of the earlier test. This is due to the fact that the slipping of a belt causes considerable loss of power, the power so lost passing off in heat. The use of Cling Surface reduces the slipping and consequently reduces the loss of power occasioned by the use of belts that slip. During the past six months I have had occasion to observe the practical use of Cling Surface in a number of instances. In all such cases Cling Surface has improved the belts by softening them, and as far as I can determine in the limited time (seven months) tends to preserve the leather of which they are constructed."

New Publication

The Growing Magnitude of Electrical Industries. Prepared by T. Commerford Martin for J. G. White & Company.

The small brochure bearing this title gives briefly an idea of the advance made in electrical interest and investments during the last few decades. The subject matter is divided into various headings devoted to the different branches of electrical interests, and interesting figures are given of each. For instance, Mr. Martin estimates the gross income of the telephone companies during the last year as about $50,000,000, and gives the number of conversations over the Bell lines as a little over two and one-quarter billions. The central electric lighting and power stations of the United States, have a gross income yearly of about $66,000,000 and are capitalized at about $600,000,000. The isolated and municipal lighting plants represent a capital investment of about $400,000,000. Of electric railway work, the writer says: "The capital liabilities of the street railways of the United States at the close of 1898, were $1,621,820,000, a gain in one year of nearly $150,000,000. A conservative, authoritative estimate made in 1897 was that the street railways were then earning gross at least $150,000,000, a fair figure in view of the fact that in three Eastern States with less than one-third of the mileage, the earnings in 1896 were $64,000,000. It is therefore safe to say, in view of the rapid growth of carrying capacity, that the total earnings in 1898 were not less than $175,000,000. It appears that 220 roads earned $130,000,000 in that year. There are about 900 roads or systems. If the net be taken at around 40 per cent, there was applicable on bonds and stock, the sum of from $60,000,000 to $70,000,000, or from 4 per cent to 5 per cent over the whole capitalization." As a summary Mr. Martin estimates the investments in all electrical industries in the United States at about $3,260,000,000.



Street Railway Journal

VOL. XV. NEW YORK AND CHICAGO, DECEMBER, 1899. No. 12.

ELECTRIC CONDUIT CONSTRUCTION IN PARIS

BY A. N. CONNETT

Your readers are probably well aware of the fact that the "trolley" has taken extremely well in France, and that now all cities are or are about to be equipped with it, Paris being the one prominent exception. In some of the larger cities certain streets have been excepted, and for relatively short districts the trolley is forbidden. The most prominent cases of this partial exclusion of the trolley are in Lyons, Bordeaux and Nice. In these three cities the French Thomson-Houston Company has built or is building the electric conduit system in place of the trolley upon the sections where the latter is not allowed.

CURVE CONSTRUCTION, SIDE SLOT CONDUIT—PARIS

In Lyons 3600 meters (2.23 miles) of conduit track is in operation; in Nice 6000 meters (3.72 miles) will soon be in operation, and in Bordeaux 4000 meters (2.48 miles).

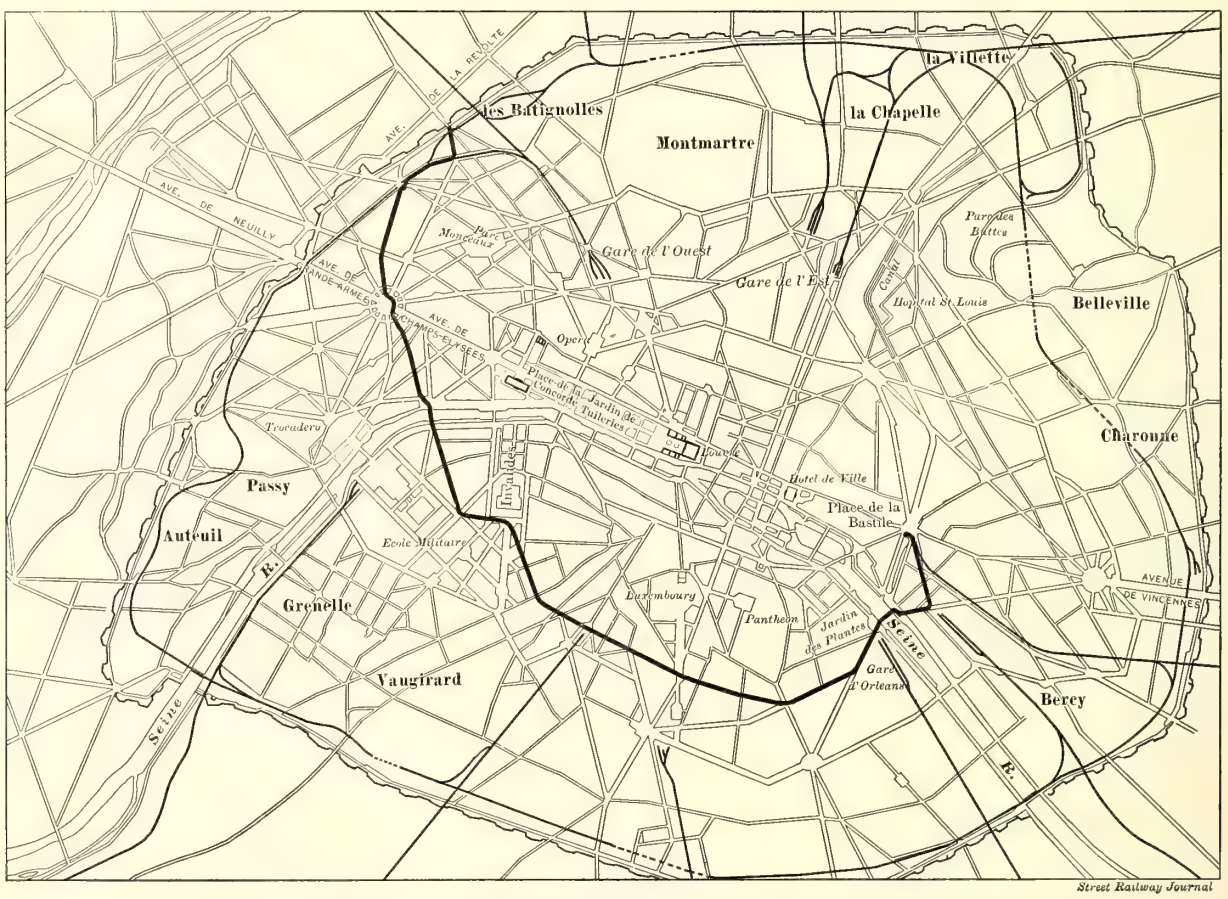
It is not exactly true to say that the trolley lines are excluded entirely from Paris. The Cie. Generale Parisienne de Tramways put in electrical operation in November, 1898, its Bastille-Charenton line, and this is almost wholly trolley. Of its total street length of 6150 meters (3.81 miles) 3520 meters (2.18 miles) are in the city of Paris, and of this 2650 meters (1.64 miles) are trolley; the rest, viz., 870 meters (0.54 miles) in conduit, is divided into two short sections, each of about equal length, one at the Place Daumesnil and the other the Paris terminus at the Place Bastille and the Rue de Lyon.

This line was built by the French Thomson-Houston Company, and has been deservedly very much praised, no expense having been spared in the construction and equipment to make it a model road. In appearance, at least, the overhead construction has never been excelled or even equaled elsewhere, as can be seen from the engraving on page 852. The service also has been excellent, comparing favorably with the best lines anywhere and far superior to any existing line in Paris.

But even with this splendid example of what service a well-built and well-equipped line can give, the prejudice

against the overhead construction still continues, and no other trolley lines are in construction or even projected at this moment. Apparently the question of good street car service must be solved otherwise. It must not be understood that mechanical traction is unknown in Paris, for in reality it is quite the contrary. There are more systems in use here than in any other city, but none of them combines the necessary attributes of a rapid, frequent service to the public, with operating expenses inviting to the shareholders.

The experience of Buda-Pesth, Washington, New York, Berlin and Brussels with conduit construction was not unknown to engineers here, but a natural desire to construct the trolley on a number of lines where the local conditions seemed ideal for this system, has hindered the construction of conduits up to now.



The Cie. Generale Parisienne de Tramways was given a new concession of a line called "St. Ouen-Champ de Mars," which will run from the Porte d'Asniéres to the Ecole Militaire, within the city limits of Paris. The concession being explicit that the system in Paris must be one of "underground electrical conductors" the company decided to equip this section of the line with conduits. The authorities also accorded the company the privilege of extending the conduits to the company's depot beyond the Gare Montparnasse. Lately the company decided to extend the conduit to the Place de la Bastille. The relation of this line to the rest of the system can be seen by reference to the map.

The conduit so prolonged will serve for three lines, viz., the St. Ouen-Champ de Mars, from the Porte d'Asniéres to the Ecole Militaire; the line from the Place de l'Etoile to the Gare Montparnasse, and the line from the last point to the Place de la Bastille. The two latter are at present important horse lines.

It will readily be seen that this is an important piece of work both from its extent, 10.5 km. (6.5 miles) of double track, and from the character of the territory through which it passes.

Some features of the conduit construction differ quite radically from anything yet done, and they may be of interest to the readers of the Street Railway Journal.

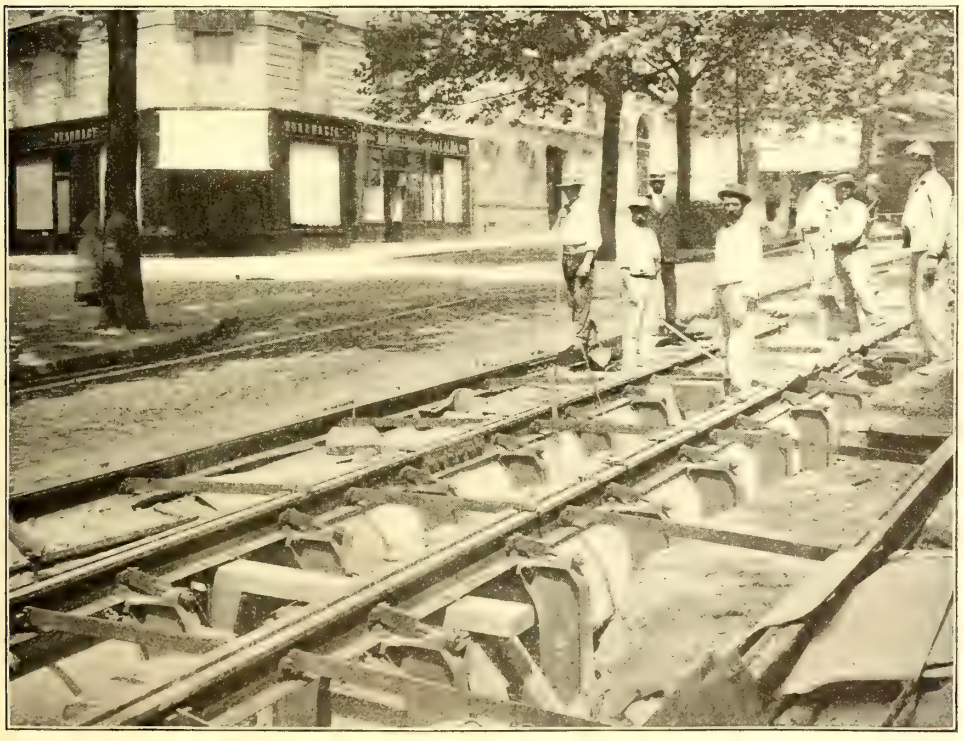
The conduits built by the French Thomson-Houston Company (and this is the only company which up to this time has constructed conduits for electric roads in France) have all been with the center slot. The type of construction in the main resembles that of the Metropolitan Railroad Company, of Washington, the important difference being that the cast iron insulator shields are bolted directly to the bottom flange of the slot rail, and the insulator pits are covered with a cast iron plate, this being low enough to allow its being paved over. This avoided the use of manholes in the street in any quantity, the municipal regulations being such in Paris that manhole covers must be entirely suppressed or reduced to a very strict minimum.

MAP OF PARIS, SHOWING LOCATION OF NEW ELECTRIC CONDUIT LINE

While the Thomson-Houston Company made every effort to continue the construction of this central slot conduit in Paris it has not succeeded and this is largely due to the question of pavement. Wooden pavement has been adopted here, as the standard. The wear is excessive, and in consequence it does not take long to leave the rail above the surface of the pavement. This is very hard on vehicular traffic, especially in a city with so many light vehicles as in Paris. Therefore the engineers in charge looked decidedly askance at the proposition of adding another line of rails in the center of the tracks. The wheel rails were regarded as necessary evils, but any other rails than these, which could be avoided, were not to be thought of. The plans of the company were therefore rejected, and it was invited to submit others which would avoid the central slot rails.

Of course there was nothing left but to do the best possible with the side slot conduit. The objections to this are:

1st. The question of slot closure becomes doubly important from the fact that the wheel flanges as well as the plow shank must pass into the slot.

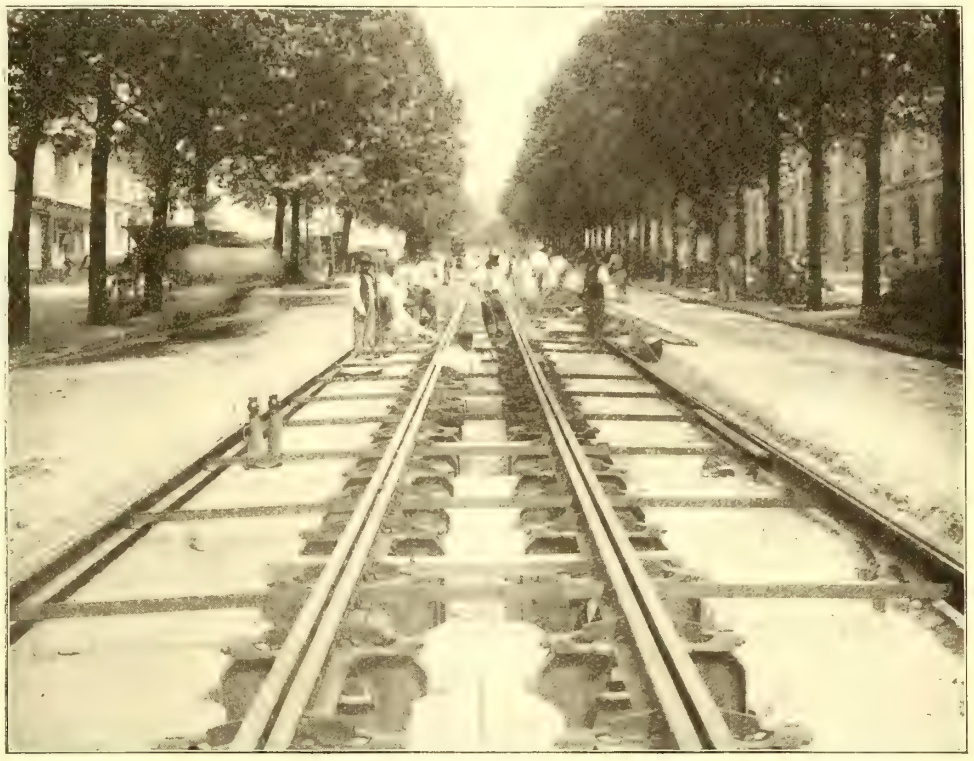


2d. The entire car traffic passing on the overhung yoke seats makes a stronger construction necessary.

3d. The plow insulation is rendered more difficult from the splash of mud and water directly on it from the wheels.

4th. It is fundamentally impossible to make a really satisfactory slot switch.

The last reason is much the most important. A wide slot is of course necessary for the wheel flanges, and the upper surface of the switch must be flush with the rail head because the wheels roll upon it. It must be very strong for this reason also, and have considerable width at the point where it must be supported. With these conditions a mechanically satisfactory switch will give a slot width of from $1\frac{3}{4}$ ins. to 2 ins. at the point. Such a width seems to be admissible in some European cities, but it needs no argument to prove that it is undesirable, and to be avoided if possible. In the Paris construction the difficulty has been avoided by the device to be hereinafter described.



The general type of construction is shown in Fig. 1. The

VIEW SHOWING CONDUIT LINE IN COURSE OF CONSTRUCTION

two conduits are interiorly placed. The wheel rails are held to gage by tie-rods spaced every 2.10 meters (6 ft. 10 11-16 ins.) and the two interior slot rails are tied together in a similar manner. The insulator, conductor rail, the clips for fastening the latter in position to the insulators are, in general, very similar in construction to those of the Metropolitan Railroad Company, of Washington, D. C.

The regular track construction is clearly shown in the engravings herewith. The metal work is tied together by the tie-rods and gaged accurately. The forms are put into

VIEW SHOWING CONDUIT LINE IN COURSE OF CONSTRUCTION

position, and then the conduit walls are formed with concrete. The sheet iron forms are afterward withdrawn through the slot. They are in three separate parts, so that this is done with extreme facility. The use of sheet iron removable forms is to be recommended from every point of view.

The construction of the road bed is extremely simple. The delay in getting material has been a constant source of annoyance, and would not warrant an organization for rapid track laying, but nevertheless, with no effort, the advancement has been about 100 meters (328 ft.) of street per diem, or twice that length of track.

The paving in and between track is wood, and outside principally Belgium block and macadam. The conduit construction has shown every sign of being amply strong. The swelling of the wooden pavement blocks has not affected the slot width. While it has stood this severe pressure well, the same cannot be said of the wheel rails. Not being supported by the concrete base of the exterior wooden paving (the usual condition) these rails have tilted somewhat. The use of wooden pavements adds a most perplexing problem to the engineer. The most unheard of things happen to the track and the engineer never knows exactly what "bizarre" effect is going to result.

To avoid the inherent difficulties of the side slot switch, the device of deflecting the slot to the center at such points

was decided upon. The engravings on page 851 show clearly this construction at the terminus of the "Etoile Montparnasse" line at the head of the Avenue Marceau. The center slot switch is then always used and the difficult problem of the side slot switch effectually avoided by "dodging." The slot switch mechanism is one designed especially for the Omnibus et Tramway Cie., of Lyons, where it has given very good results. Figs. 2 and 3 show this in plan and section respectively. The slot and track

The line crosses the Seine on what is called the Pont Alma. The height over the masonry arches would not permit the regular conduit construction. A special conduit was designed for this; see Fig. 4. It is a continuous cast iron tube, reinforced by an exterior web every 1.05

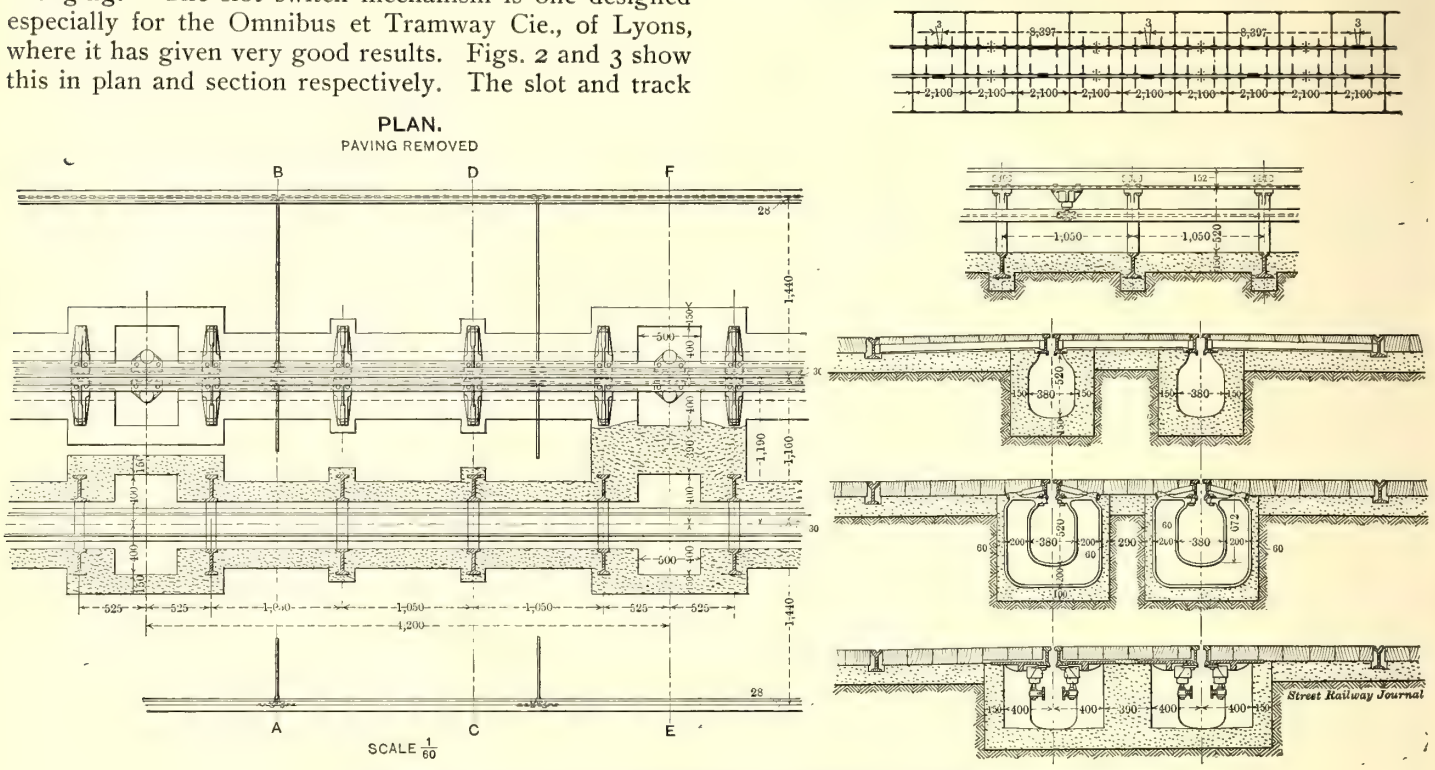


FIG. 1.—PLANS AND SECTIONS OF UNDERGROUND CONDUIT CONSTRUCTION—PARIS

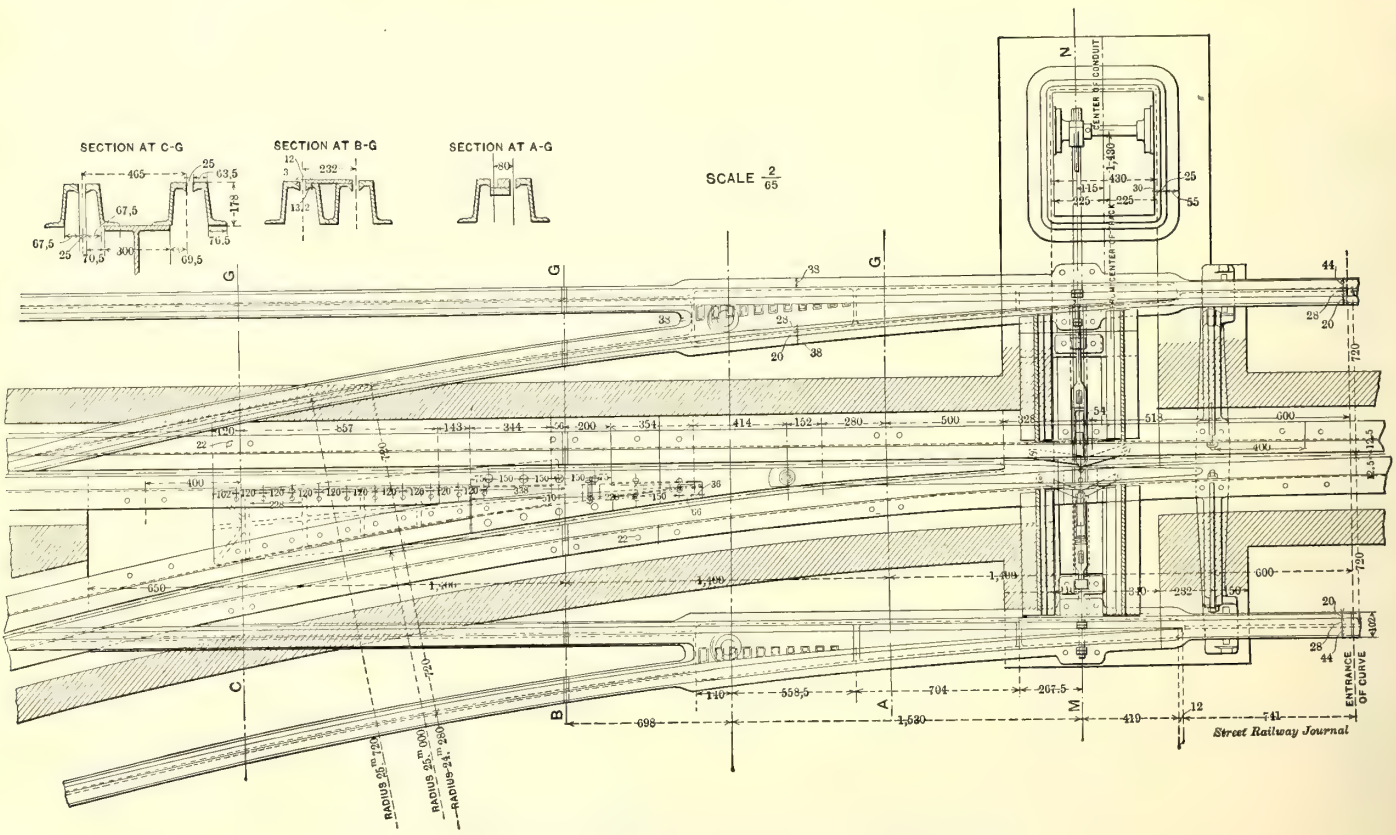

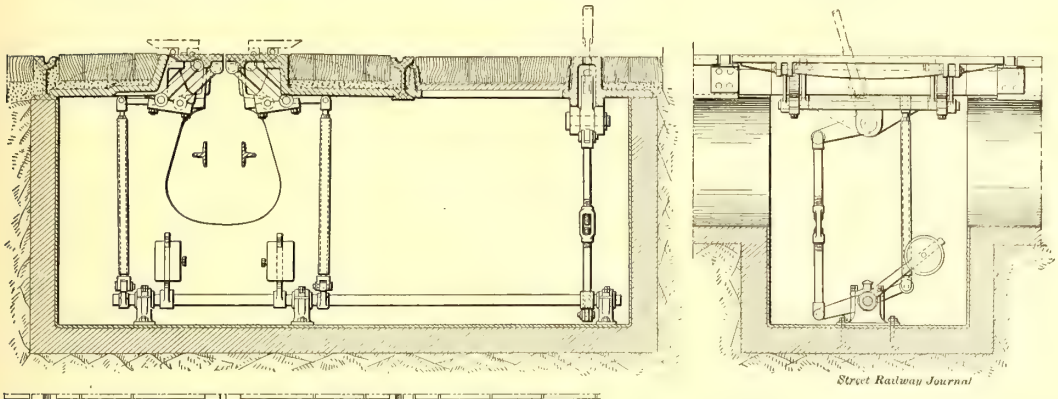

FIG. 2.—SWITCH MECHANISM, WITH SLOT IN CENTER OF TRACK

switches are thrown into position together by a pull on the detachable switch lever placed outside of the track. The arms which push the slot tongue are inclined to the slot. The plow in passing pushes them back under the slot rail. The force required to do this is so very slight that there is no danger of damage to the plow or the plow carrier.

meters (3 ft. 5 ins.). The tubes are covered with steel plates upon which a special Z bar is bolted, this forming the slot rail. Special steel castings act as tie-rods to hold the slot rails in position. This construction requires raising the conductor bars 12 cm. (4¾ ins.) above their level in the normal conduit. Special means to raise and lower

the plow for the passage over this bridge are therefore necessary.

The "St. Ouen-Champ de Mars" line being partly trolley and partly conduit special requirements are necessary at the points of contact of these systems to make it possible. The necessity of cars running at will on conduit and overhead systems is one common to all European conduit roads. This problem has been solved on two unimportant lines in the United States by the crude method of attaching and detaching the plow at these points. For an important line where this manoeuvre must be made many hundreds of times a day the question of making the change without an appreciable loss of time becomes important. The placing of men in vaults under the street is also to be avoided if possible.

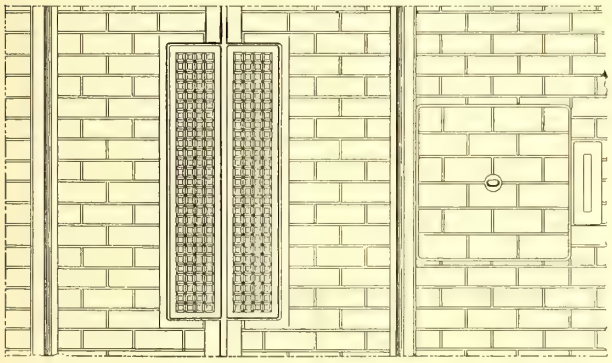

FIG. 5.—ARRANGEMENTS FOR WIDENING SLOT TO PERMIT REMOVAL OF PLOW

The problem has been very ingeniously solved on the Continental roads at Berlin and Brussels, and the latter roads at Buda-Pesth. It has been recognized that the simplest and most practical solution was to carry the plow on the car always, and to provide the proper means on the car of raising it from or lowering it into the conduit. The plows are designed to pass through the normal slot, therefore they can be raised or lowered at will anywhere on the conduit line. This involves a question of permissible slot width which

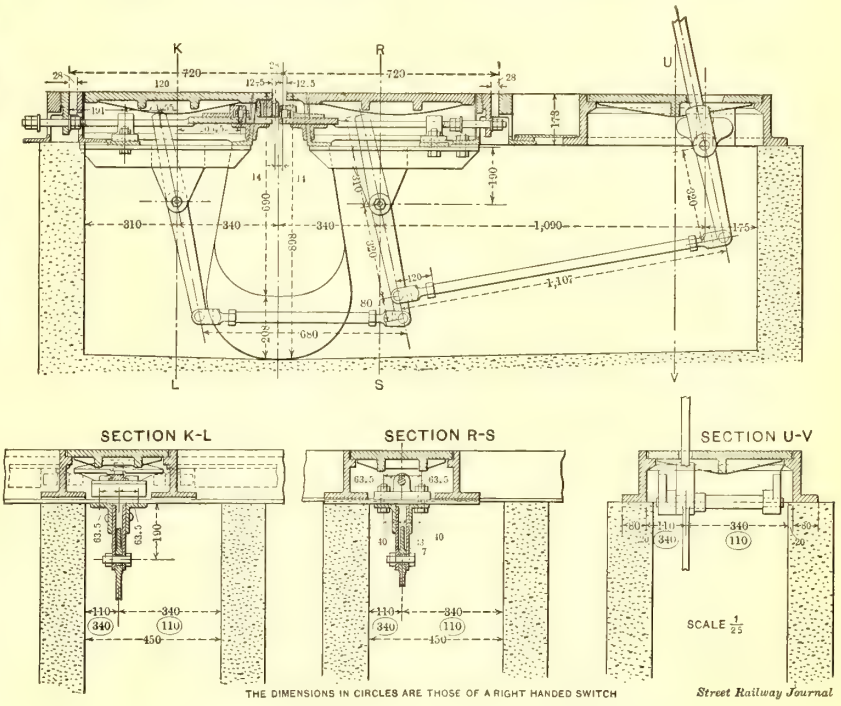

FIG. 3.—SECTIONS OF SLOT SWITCH MECHANISM

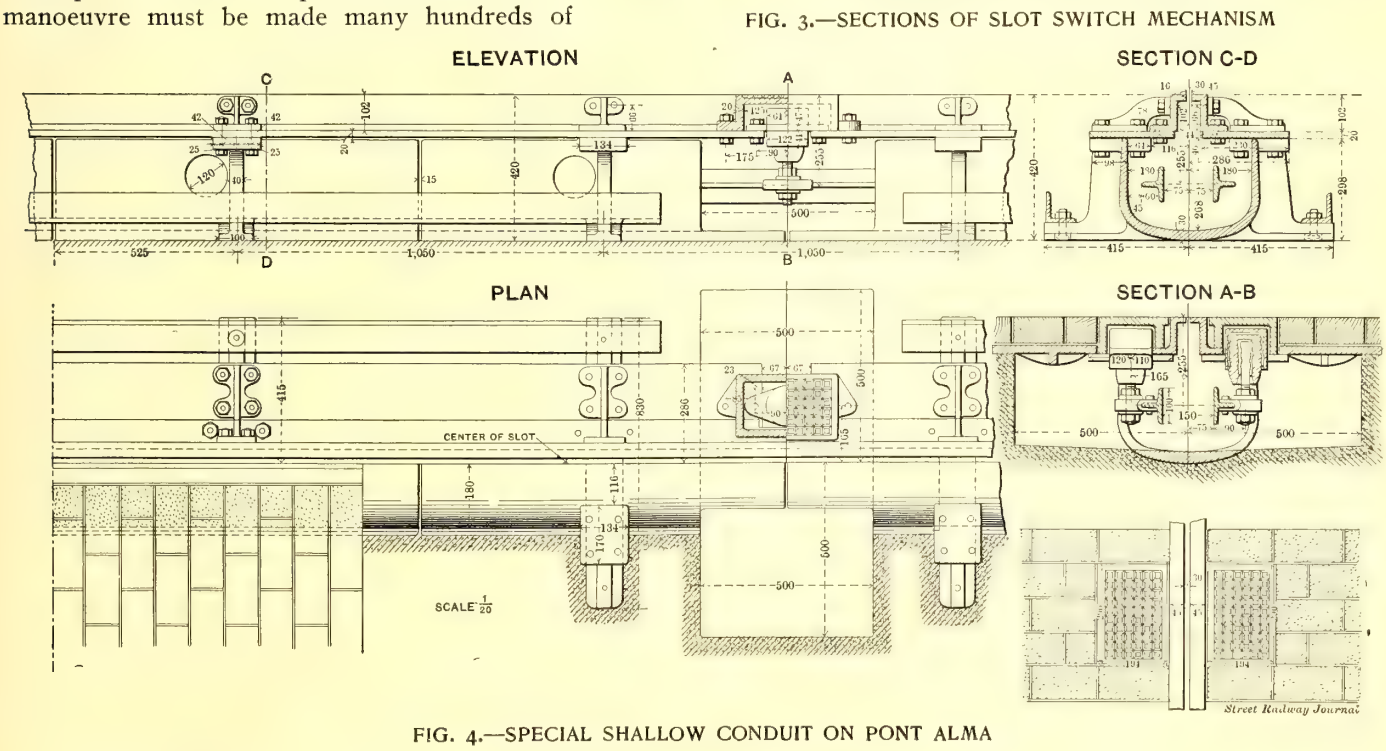

FIG. 4.—SPECIAL SHALLOW CONDUIT ON PONT ALMA

would make it impracticable for all American and many European cities. Besides it requires a form of plow construction of which many engineers would not approve. The writer, after giving the matter much thought, decided to adopt for the conduit lines of the French Thomson-Houston Company the main idea of the plow he had successfully used in Washington, viz., cast iron shoes pressed sideways by light semi-elliptic springs, the shoes being supported by horizontal links which limited their outward play. These links make the question of the mechanical strength of the springs unimportant, as they carry the shoes and resist all of the shocks; the role of the springs therefore is simply to lightly press the shoes against the conductor rail. At the same time he adopted some excellent ideas from the plows designed by the General Electric Company, for New York, which increased very materially the insulation resistance of the Washington plows while retaining the excellent mechanical features of the latter.

But starting from the point that for the best interests of operation such a form of plow was superior, it was necessary to give up the advantages of being able to raise or lower the plow from or into the conduit without a special construction. The advantage claimed by the adherents of the other method of being able to do this anywhere on the conduit line is of slight practical value. But the fact of

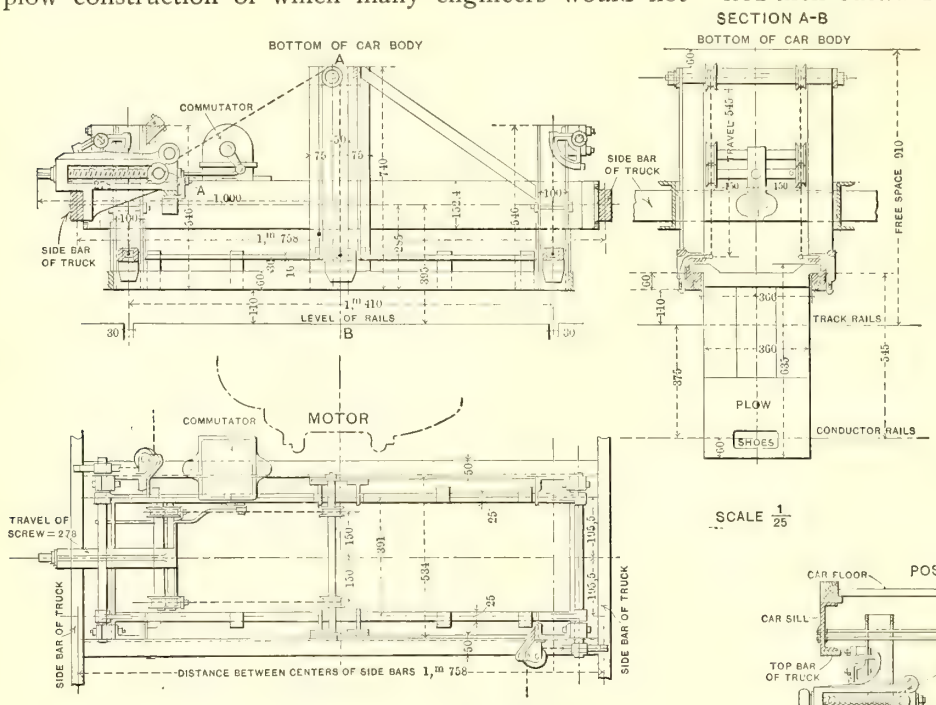

FIG. 7.—METHOD OF SUPPORTING AND RAISING PLOW

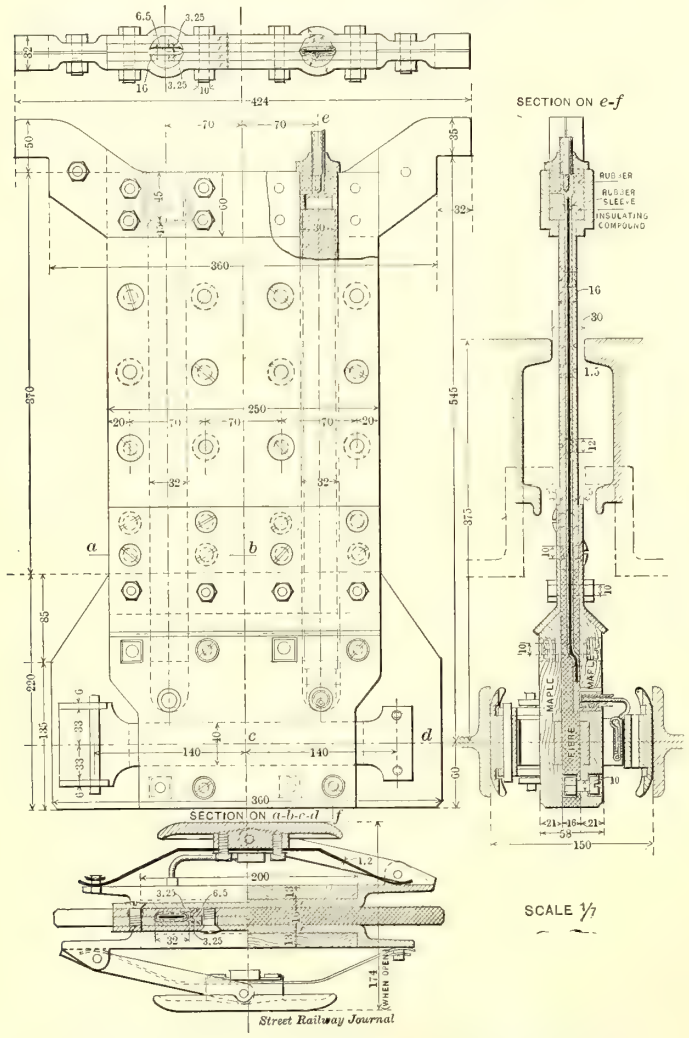

FIG. 8.—SECTIONS AND SIDE ELEVATION OF PLOW

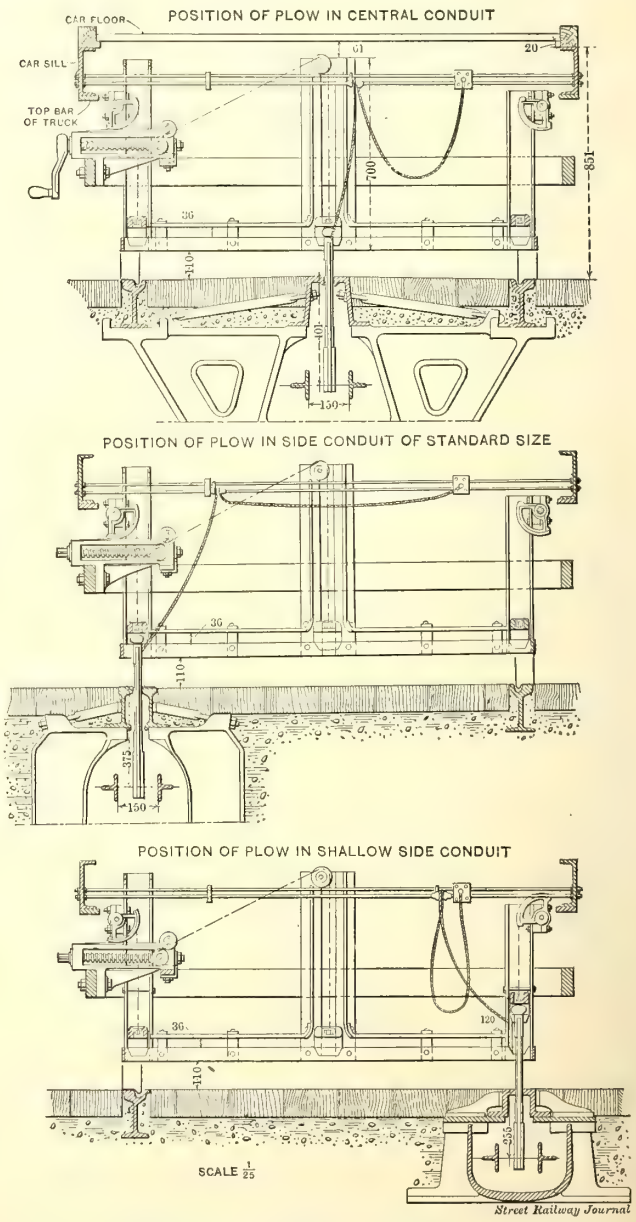

FIG. 6.—SECTIONS SHOWING POSITION OF PLOW IN DIFFERENT TYPES OF CONDUIT

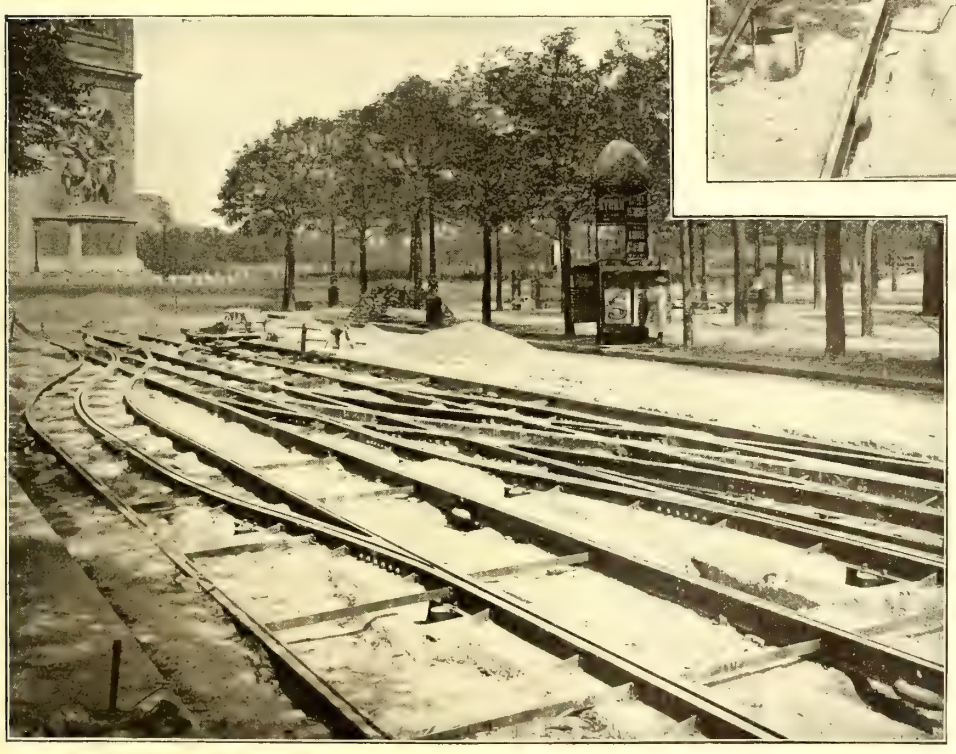
being able to do it at the points of contact of trolley and conduit lines without any special construction is a decided advantage. The problem of making an opening in the slot wide enough to allow the plow to pass through and which could be opened and shut quickly by a sure and simple mechanism was a rather difficult problem to solve. The one finally chosen (Fig. 5) has proved most successful in Paris and Lyons, and has been adopted as the standard of the company. In the slot are placed two cast steel covers, supported on one side by a cast iron frame, and the ends by angle irons bolted to the slot rails.

These covers are raised to the dotted position shown in the drawing by a simple motion of a removable lever placed outside of the track. The use of counter weights makes this operation an exceedingly easy one. Sheet iron guides (not shown in the drawing) are fastened to the conductor rails, and direct the shoes when the plow is lowered. The covers are opened by the conductor, who, at the same time, raises or lowers the plow from the side of the car by the device to be explained. If the car traffic is very heavy it pays to have a man for this who takes care of two traps, one for each track, and placed side by side.



The most difficult problem has been in the design of the plow carrier. The conditions necessary to fulfil were:

First. That the plow should be able to slide laterally the full width of the track.

Second. That at its central position it could be raised clear from the conduit so as to be carried over the trolley section, and vice versa, to be lowered into the conduit.

Third. That it could be raised and lowered from each of its side positions the necessary distance between the height of the conductor rails, so as to pass the shallow conduit of the Pont Alma.

Fourth. That at the contact points of trolley and conduit, the circuits could be changed automatically with the same operation of raising and lowering the plow. This change is rendered necessary from the fact that the conduit circuit is a completely insulated one, while on the trolley the return is by the rails. The advantages of this change being automatic are self evident.

VIEWS AT HEAD OF AVE. MARCEAU, SHOWING METHOD OF DEFLECTING SLOT FROM SIDE TO CENTER OF TRACK AT SWITCHES

Fig. 6 shows the plow in the three different conduits, and gives a general idea in section of the operating mechanism. The plow is deflected to the center, and is raised or lowered by means of the trap already described (Fig. 5). The plow carrier is shown more in detail in Fig. 7.

The plow is raised from its central position by means of the screw bolted to the side bar of the truck. This

screw is turned with a controller handle. The switching of the circuits is accomplished at the same time by the bar attached to the "commutateur." The necessary motion is given to the crank handle attached to the cylinder, at the ends of the course of the block "A," insuring that the switching of the circuits takes place at the proper moment.

This "commutator" is in construction based on a car controller, with fingertips, cylinder, and a spring to make a quick break and so avoid destructive arcs. It is a very important mechanism. With some modifications dictated by the results of experience, it has proved itself entirely satisfactory.

This entire lifting device is the same as that employed on the Bastile-Charenton line, at Lyons, Nice, etc., with the exception that on these lines the lifting chains are attached directly to the plow. This becomes impracticable in this case, where the plow shifts its position the entire width of the track. The chains are therefore attached to a "cage" in which the plow slides. This "cage" must be

fixed mechanically in position, so that it will not be an obstruction to the plow in its side movement. At the same time the movement of the chains should release the "cage" without any additional manoeuvre.

Fig. 7 shows in section the hook for this purpose. The pull of the chain first releases the hook and the "cage" with the plow slides up the ways provided for this purpose. In the casting opposite the hook a hole is drilled (not shown in the drawing) in which is placed a small spiral spring, which acts to engage the hook when the "cage" descends to its seat.

The same apparatus is shown at each end of the slides to lift the plow for the passage over the shallow conduit. As shown on the drawing this is intended to be done by the motorman from the car platform. This operation in reality will be done by another mechanism from the side of the car, it being considered safer to bring the car to a standstill, and release the motorman of any other responsibility than to stop his car at the proper point. The drawings are not sufficiently advanced to show this modified mechanism.

TROLLEY LINE, PLACE DAUMESNIL—PARIS

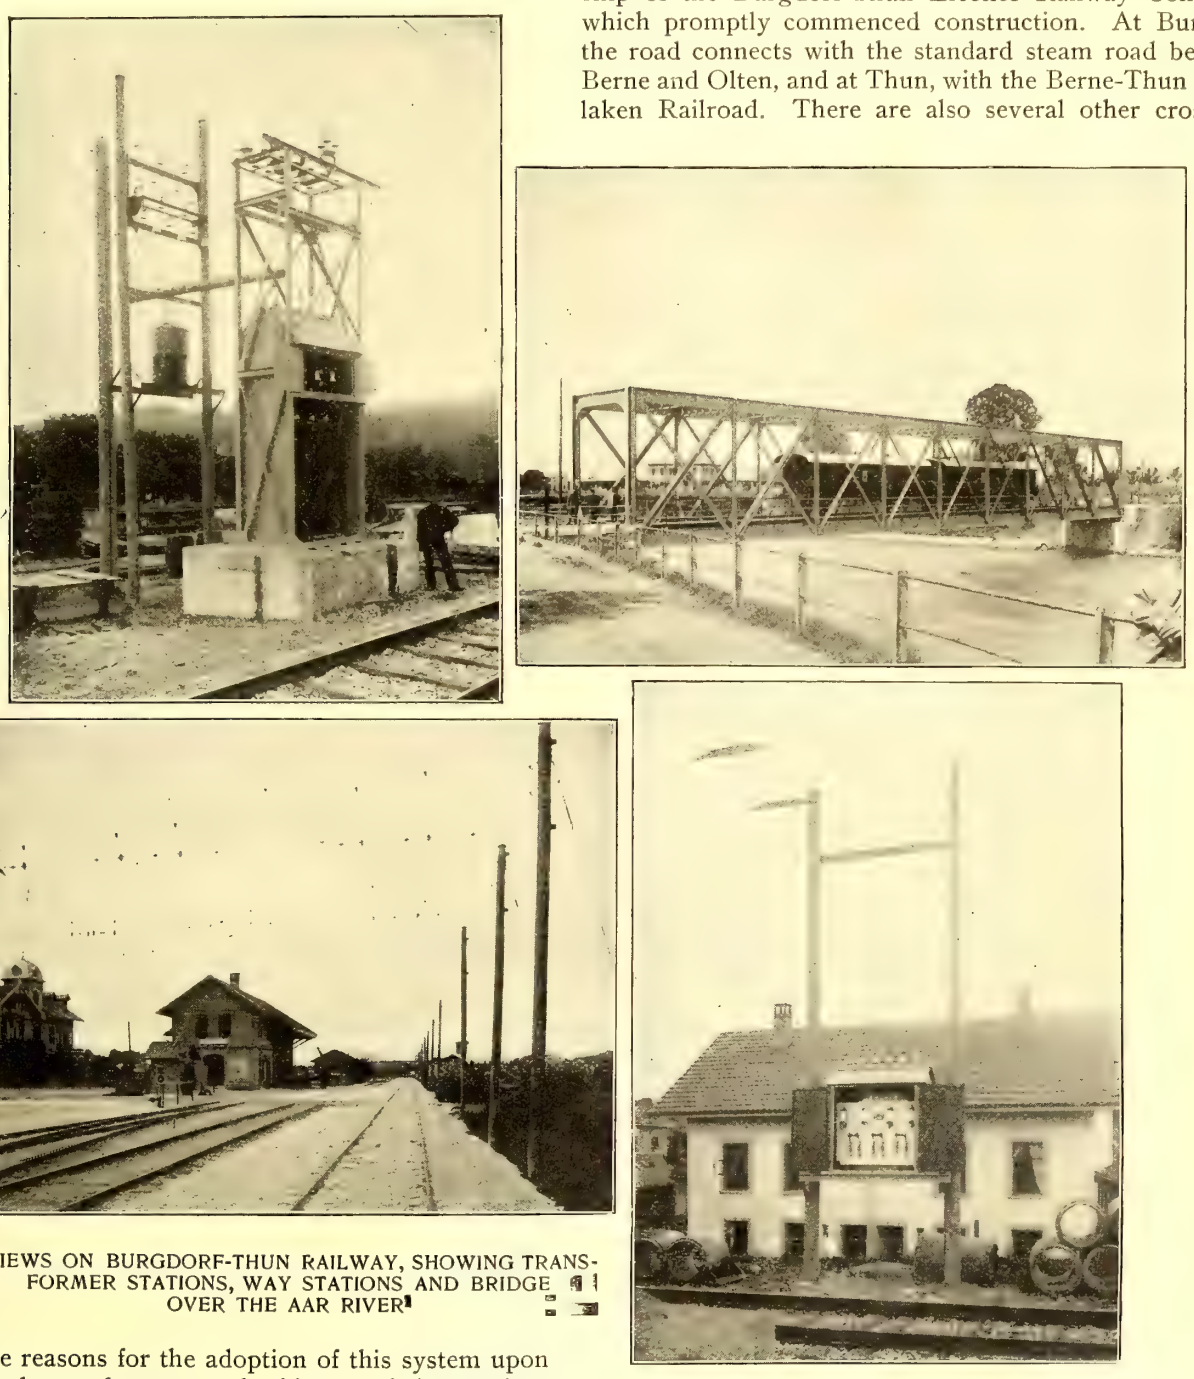
The plow design needed a special study. The type already in such successful use for the central slot not being at all applicable for the side slot or the shallow conduit, another form had to be adopted. That finally selected is shown in Fig. 8. It offers all of the advantages of the "Bastille-Charenton" type, while being much simpler in construction. This plow should give an excellent account of itself.

This line has numerous other points which have required special construction and perhaps additional information will be given in another article, but for the present enough probably has been said to show that the line is one having some special points of interest.

High Speed Service on Private Right of Way in Buffalo

The International Traction Company has recently put in service a new route for its Buffalo and Lockport branch. On account of the length of this line, high speed and a private right of way are almost imperative. Between Tonawanda and Lockport the cars always have run on the Erie railroad tracks, but heretofore, between Tonawanda and Buffalo, they have used the tracks of the Niagara Falls line, which extend along the highway.

The new route between Tonawanda and Buffalo consists of about 6 miles of track from Tonawanda to Buffalo city line, where the cars turn into Main Street, near Cold Spring, and thence run down town. The new private right of way has allowed a considerable reduction in the schedule running time, which is now seventy minutes between the downtown section of Buffalo and Lockport. The time on the New York Central road is from fifty minutes to fifty-five minutes. Of this seventy minutes, thirty minutes are spent on the streets of Buffalo, the average speed on the private right of way being 45 miles per hour between stops, with maximum speeds running up to nearly 60 miles per hour. The new road is single track, and laid with 85-lb. American Society Standard rail. The whole line is operated by a regular train dispatching system exactly like that of steam roads. The passenger cars run every thirty minutes throughout nearly the whole day.



The overhead construction used involves some new features, which were introduced by the electrical engineer, C. K. Marshall. The overhead wire is carried on brackets, but instead of suspending the trolley wire immediately from the brackets, a 7-16-in. stranded steel cable is strung the whole length of the line, and the trolley wire is hung from this cable by means of ordinary straight-line hangers offset on the cable a considerable distance from the brackets. This gives flexible suspension, and in addition prevents any break of the trolley wire from twisting out of shape several brackets. The International Traction Company has also directed the General Electric Company to gear up one of its freight locomotives for experimental purposes to determine its applicability to passenger train service. The locomotive will be geared to give a maximum speed of 70 miles per hour, and if this speed can be attained with a load of 150 tons, electric locomotives will be used on the Erie tracks between Buffalo and Niagara Falls to haul regular Wabash and other passenger trains.

E. G. Tillston, Jacob Mandlebaum, H. R. Newcomb and others, of Cleveland, have acquired control of about four-fifths of the capital stock of the Dayton Traction Company, and have been elected to the directorate of the company. It is said to be the intention of the syndicate to consolidate the property with that of the Cincinnati & Miami Valley Traction Company, and the Cincinnati & Hamilton Electric Railway, which it now owns. Mr. Mandlebaum is quoted regarding the deal as follows: "Our plans are not yet in shape to be discussed. All that I can say is that we now have a line practically completed from Cincinnati to Dayton. When the reorganization is carried out, which will be very shortly, enough bonds will be left in the treasury of the (new) company to pay for the extension of the line through to the northward from Dayton, the whole length of the Miami Valley to Troy. This will, I believe, be the longest trolley line in existence. The valley of the Miami is the richest territory in the State, and I regard Dayton as the best traction town in the State. The road, when completed, will be about 72 miles long, and will traverse a territory having a population of 750,000. Practically the whole enterprise is a Cleveland affair.

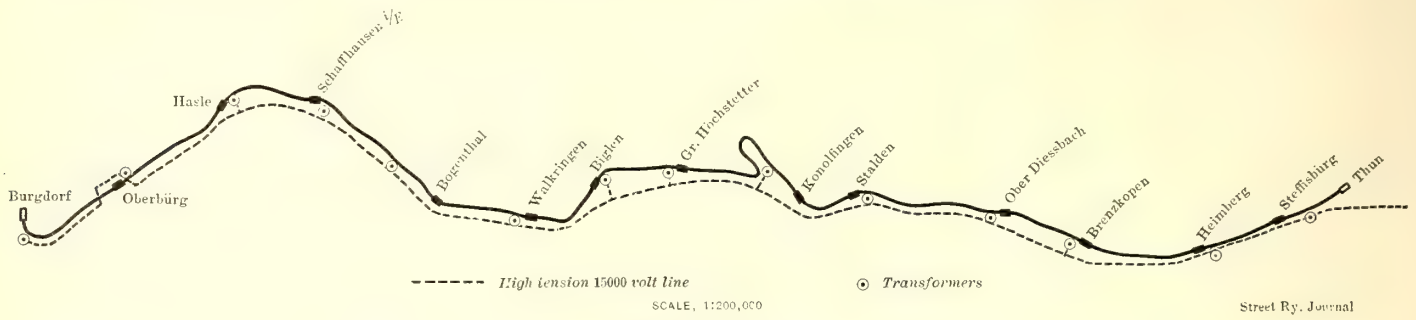
Important Three-Phase Electric Railway in Switzerland

BY CHARLES ROCHAT

On July 21, last, a railway was put in operation in Switzerland which will mark an interesting epoch in the history of electric railroading. The road referred to is that connecting Burgdorf and Thun, about 40 km. in length, and is noteworthy from the fact that it is the first extensive line to employ the three-phase current, and is as well the largest road of this type which has ever been installed. To understand the reasons for the adoption of this system upon this road a short reference to the history of the employment of the three-phase system is necessary.

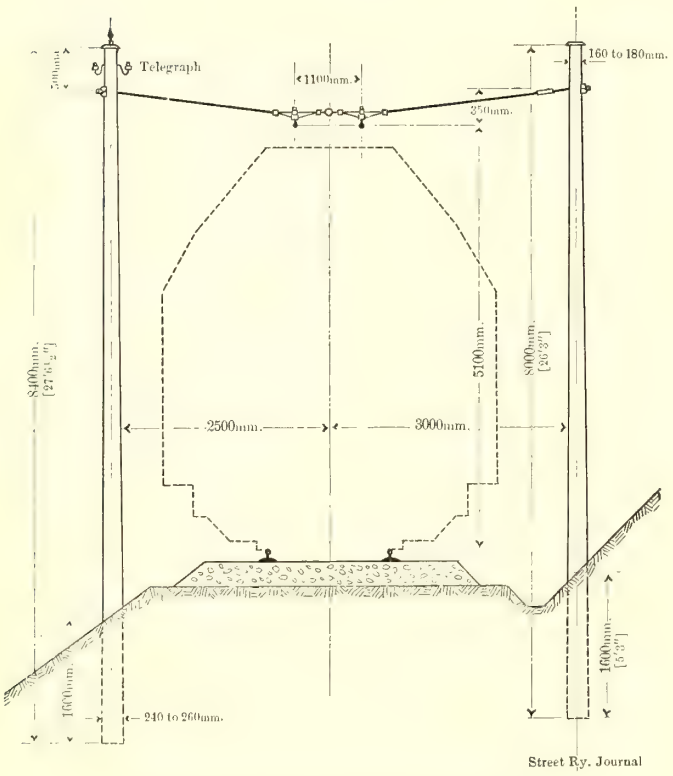
VIEWS ON BURGDORF-THUN RAILWAY, SHOWING TRANSFORMER STATIONS, WAY STATIONS AND BRIDGE OVER THE AAR RIVER.

It was on June 1, 1896, and at Lugano, that the first electric railway to use three-phase current on its trolley lines was put into operation. The experiment, having given satisfactory results, was followed on Aug. 20, 1898, by the three-phase mountain electric railway at Gornergrat, near Zermatt. Sept. 20, 1898, saw the opening of the first section of the Jungfrau Railway, and Oct. 5, 1898, the electric railway from Stanstad to Engelberg. Finally, on July 21, 1899, as stated above, the electric railway connecting Burgdorf and Thun, the most important of all those mentioned, was put in service. The three-phase alternating current has thus assumed within three years an important position in Swiss tramway and railway enterprises, and will certainly be employed on a large number of future lines, where the conditions presented are similar to those where it has already been adopted.



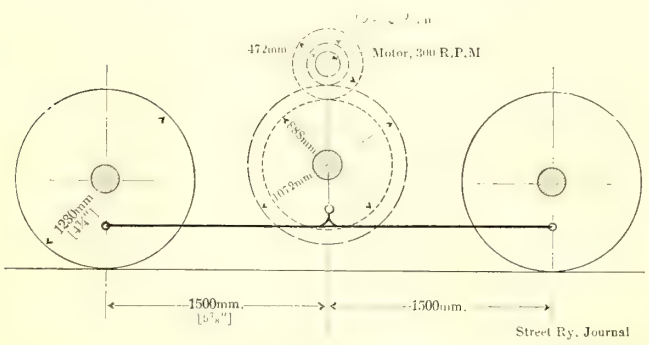
Franchises for the construction of the electric railway from Burgdorf to Thun were acquired as early as the year 1873. After many negotiations the various concessions granted were finally united, and in 1896, came into ownership of the Burgdorf-Thun Electric Railway Company, which promptly commenced construction. At Burgdorf the road connects with the standard steam road between Berne and Olten, and at Thun, with the Berne-Thun Interlaken Railroad. There are also several other crossings with steam railroads. In order to make close connections with each of these lines a larger train service was necessary than would have been possible with steam power; and, again, the grades, though not very steep, would yet have been considerable for steam operated trains. With electricity, on the other hand, the grades could be easily surmounted, and single cars could be run frequently.

The road is single track and of 3-m. gage. The minimum curve radius is 250 m., and the maximum grade 2½

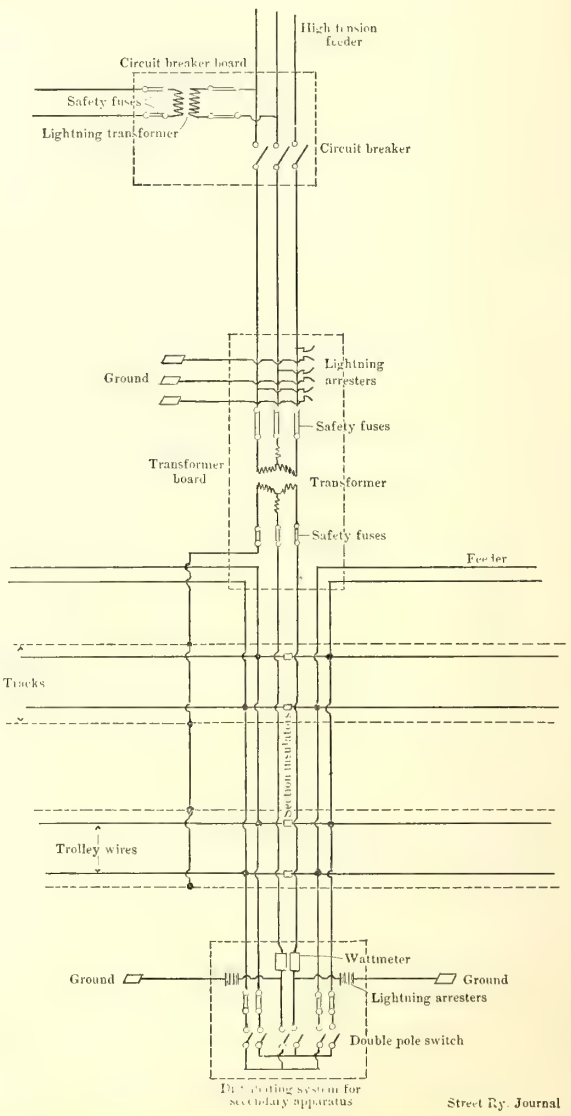


per cent. The sidings are 200 m. in length. The road passes through a number of tunnels, the minimum width of which is 4.4 m., and the height above the ties 5.4 m.

The track is laid with 36-kg. rails in 12-m. lengths. The ties are of metal, 2.4 m. long, weigh 45.5 kg. each, and



Moreover, about every 100 m. the two rails are cross-connected by an 8-mm. wire. It is premature yet to determine the results of this method of bonding, as a time test only will give correct information, but it is certain that the method has certain advantages.



MAP OF ROUTE

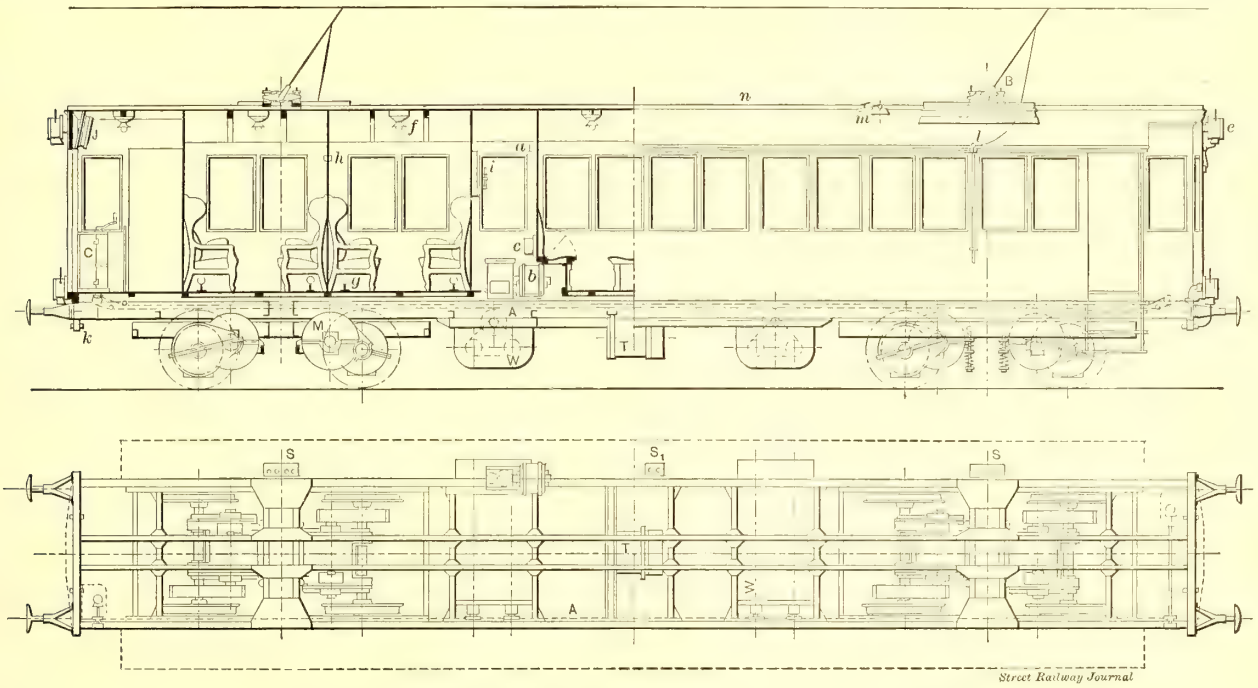
STANDARD CROSS SECTION OF TRACK

LOCOMOTIVE GEARING

ARRANGEMENT OF CONNECTIONS AT TRANSFORMER STATIONS

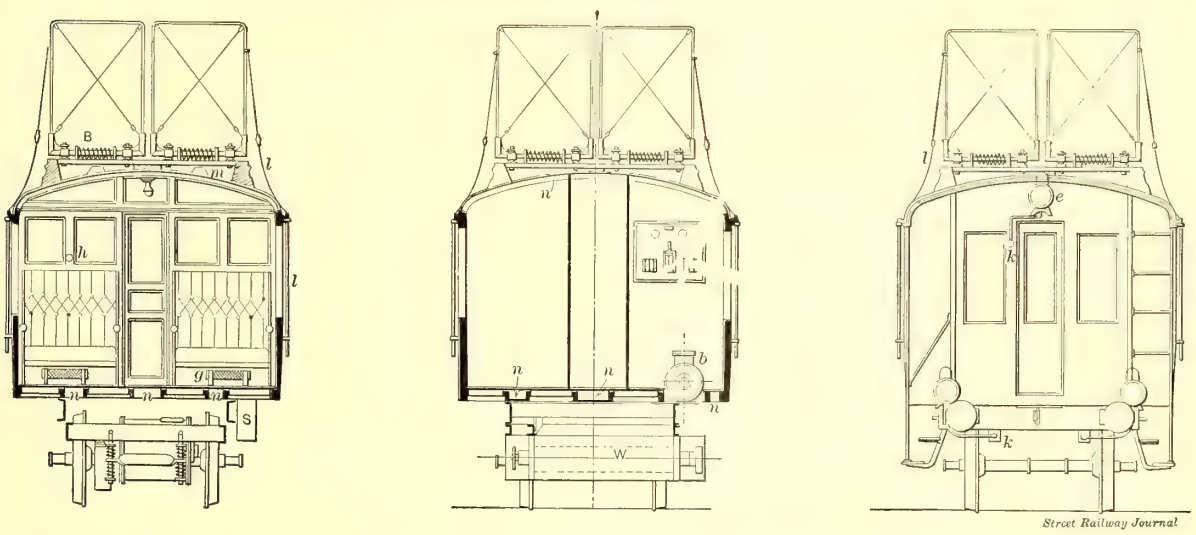
are spaced fifteen to the rail length. The complete track weighs about 110 kg. per running meter. The rails are connected to the ties by lugs and bolts, and the track construction is very similar to that used in the ordinary trunk line railroads of Switzerland, where the running weight is 15 tons per axle. A special kind of bonding is used, the object being to avoid the possibility of the bonds breaking through the vibration of the rails. The under side of the head and the upper part of the base at the end of each rail have been grooved and filled with zinc, as have also the portions of the angle-plates bearing upon these parts.

Commencing at Hasle, going from Burgdorf, the line enters a very picturesque region, where the construction was considerably more expensive than that previously encountered. There are three tunnels, of 150 m., 95 m. and 100 m. length, and two viaducts 20 m. and 54 m. in length. The stations are most attractive, and as complete in all parts as those of standard steam railroads.



Owing to the use of the three-phase system, two trolley wires are carried over the track, and the transformer stations are fourteen in number.

There was considerable discussion as to whether the



15,000-volt distribution circuit should be located along the track, where, of course, the facility for inspection was better, but where, on the other hand, it would have to follow all the curves of the line. It was finally decided to place the pole line independent of the track, wherever a saving in length could be effected. The primary circuit consists of three copper wires of 5-mm. diameter, carried on porcelain double-petticoated insulators mounted on wooden poles. The maximum span is 35 m. Between the power station at Spies and Thun (about 10 km.) wires are carried on latticed poles set in concrete. The high-tension line is protected at the entrance of the power station and at each transformer station by Siemens lightning arresters. To avoid short circuits to the earth after atmospheric discharges, water rheostats are introduced on the earth connection of the lightning arresters.

The transformers are placed at the side of the track, and are inclosed in metal housings, with wooden shutters, and supported on concrete bases. The housings are surmounted with the overhead construction necessary to receive the high-tension wires, lightning arresters, etc. The operation of all the apparatus is very simple, and is in charge of the station master. The transformers are oil insulated and have a capacity of 450 kw. each.

The contact wires, which are two in number, are of copper, 8 mm. in diameter, and are carried 5.1 m. above the track and 1.1 m. apart. Double insulation is employed between the trolley wires and the poles. The latter are

CROSS SECTIONS OF MOTOR CARS

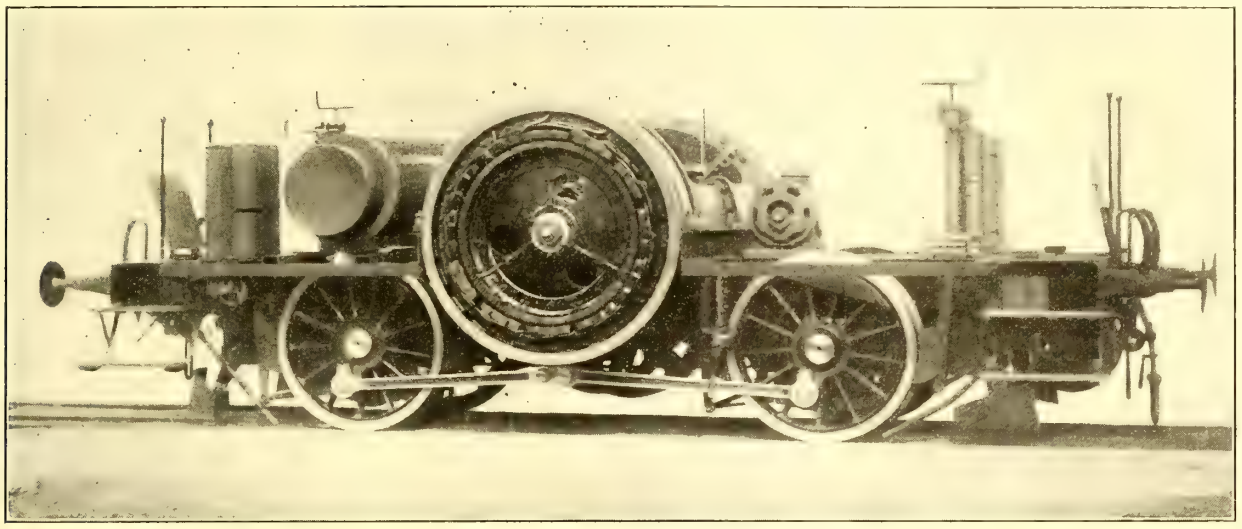
generally spaced 35 m. apart, but at a shorter distance at the curves. The principal difficulty so far experienced has been the overhead frogs. For this reason the firm of Brown, Boveri & Company, who made the installation, decided to install the bow sliding trolley, as this had been employed with success on the Gornergrat and Stanstad installations, as described in the Street Railway Journal

The power station is located at Spies, on the Kander River, and contains four groups of turbine generators. The turbines operate under a fall of 63 m., with an average volume of 10,000 litres of water per second, from which a maximum power of 6300 h.p. is obtainable. The current is produced by generators at 4000 volts, which is raised to 16,000 volts by means of transformers similar to those

PLAN AND SECTIONS OF LOCOMOTIVE

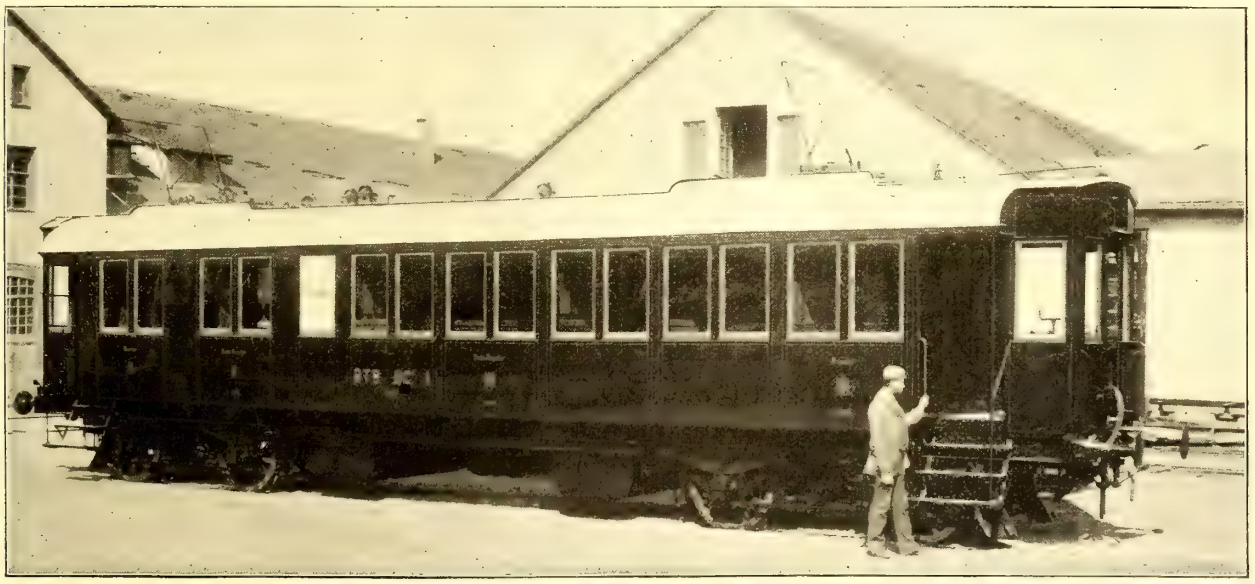
ARRANGEMENT OF CONNECTIONS AT TRANSFORMER STATIONS

for February, 1899. There are properly no overhead frogs except at the turnouts. At these points, where the wires cross, section insulators have been installed, and, as the motor cars always carry four trolley poles, two at each end, contact with at least one set of trolley wires is always secured. The normal position of the poles is vertical, although they take a slight inclination as the car moves. They are kept rigid by the use of cross-braces.



placed along the line. The lighting circuits are kept distinct from the power circuits, so that there are no fluctuations in the lighting voltage from variations in load on the power wires. Each generator has a capacity of 900 h.p., and the station when completed will have a capacity of 6000 h.p.

The company owns two electric locomotives, six motor cars, seven trail cars of different types, and three combina-

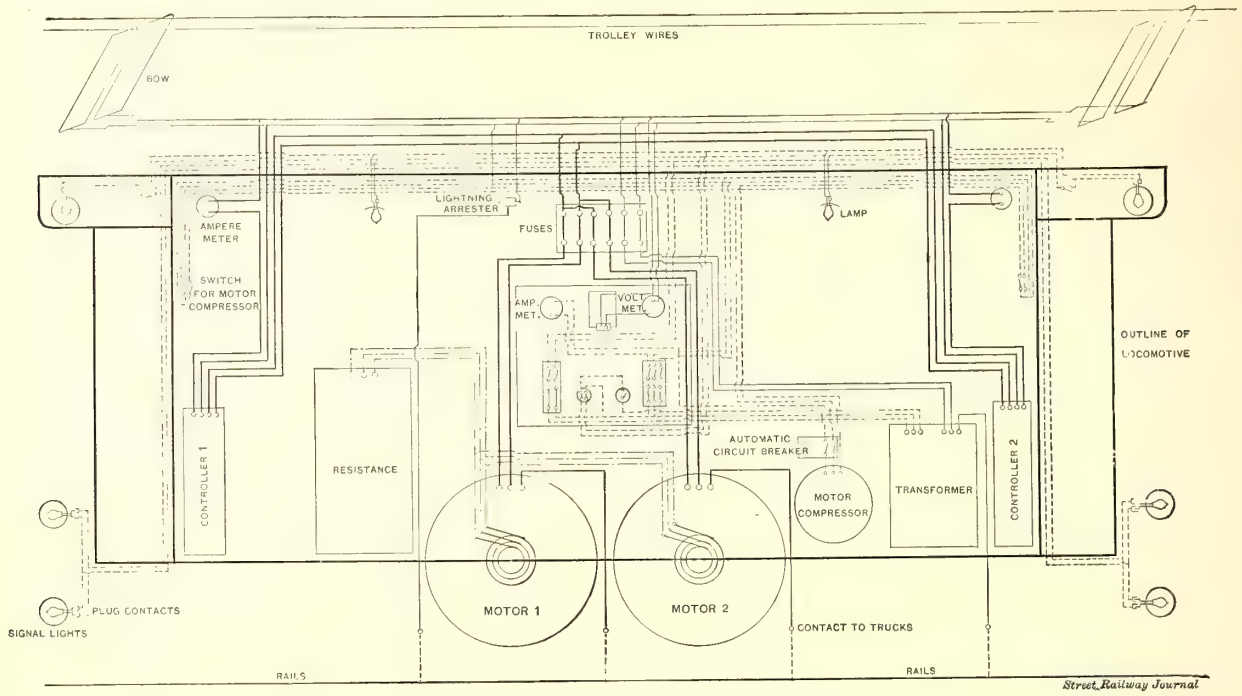


tion baggage, postal and passenger cars. The electric locomotives are principally employed for freight traffic, but are also used for passenger service. Each has a capacity of hauling 100 tons at a speed of 18 km. per hour on a grade of 2½ per cent, or 50 tons at a speed of 36 km. per hour on the same grade; the latter when hauling passenger cars. Each locomotive is equipped with two motors of 150 h.p., running 300 r.p.m. at 750 volts. They are placed in the middle of the locomotive and at either end of the same shaft. The rotors are keyed to the shaft, while the stators are mounted on the frame-work of the locomotive. The rotor shaft can be thrown into gear with either of two trains of gears connected with the axles. One of these is for use at the slower speed of 18 km. per hour, and the other for the higher speed of 36 km. For facilitating the mounting and dismounting of the rotors the sides of the locomotives are supplied with openings, through which the shaft can be removed. The collector brushes and rings can be inspected from within the locomotive.

The starting rheostat is composed of helical coils of ribbon, separated into three sections corresponding to the three phases, and connected to a commutator fitted with carbon brushes, by which the resistance can be cut in and out of circuit. At each end of the locomotive are two switches, of which one is for making and breaking the circuit, and the other for transposing the connections. The handle for operating the former also controls the starting resistance. This arrangement is to prevent the admission of current unless all resistances are in circuit.

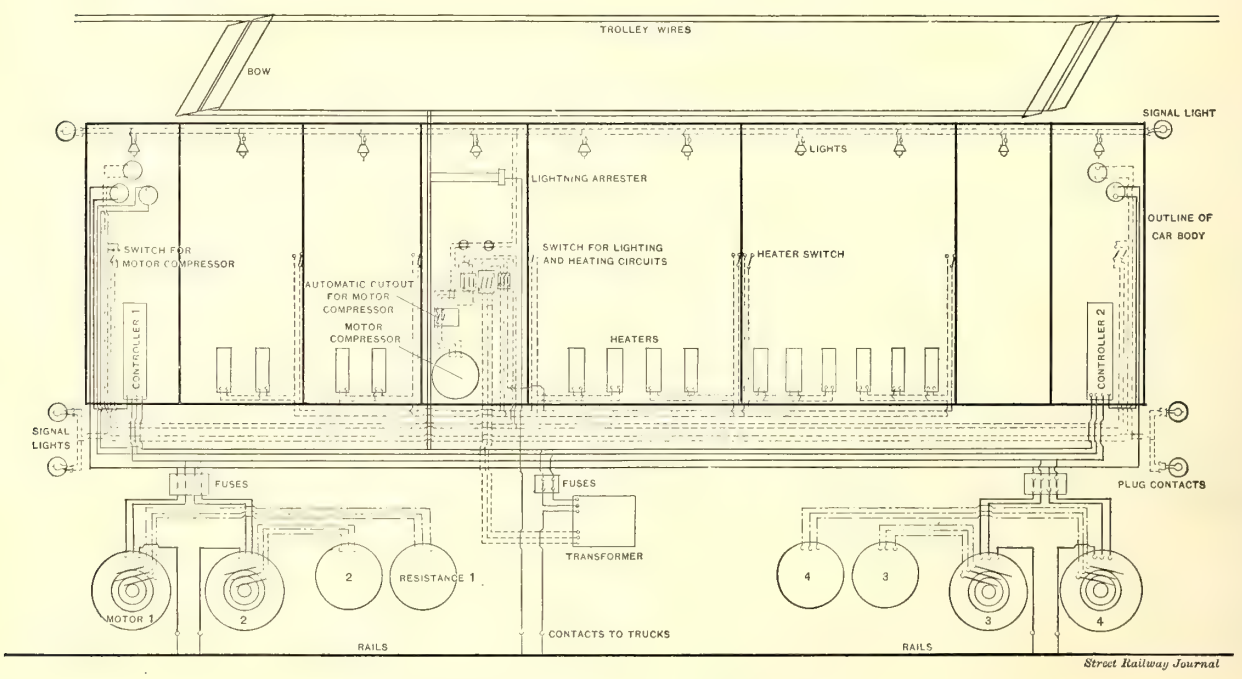
Each locomotive also carries a transformer for reducing the voltage from 750 volts to 100 volts. Part of this low tension current is used for operating a motor compressor for the use of the air brake, and part for lighting the car. The lower tension is preferred first, since it was hardly possible to build so small a motor for 750 volts, and, second, to avoid introducing into all parts of the cars and locomotive a voltage of 750. Current for light and heat is taken from two phases only, although the compressor motor is connected across all three phases. The motor compressor is of 3 h.p., and is cut in and out of circuit, as the needs of the pressure in the air reservoir require.

LOCOMOTIVE WITH CAB REMOVED



STANDARD DOUBLE-TRUCK MOTOR CAR

To measure the current used each car carries an ammeter for the motor circuit, one for the motor compressor circuit, and a voltmeter for the 750-volt circuit. This apparatus is carried on a panel on one side of the locomotive.



Lightning arresters are placed on both trolley circuits where they enter the cars, and are of the Wurts type. Electric headlights, made up of three lamps, are used, but the

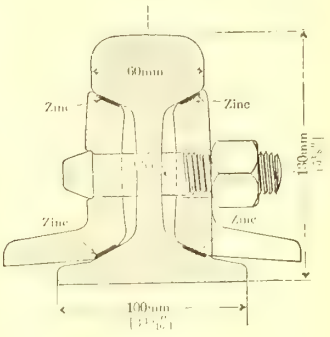
cars also carry oil headlights for emergencies. The principal dimensions of the locomotives are as follows: wheel base, 3 m.; length of body, 6 m.; length between buffers, 7.2 m., and diameter of wheels, 1.3 m. Weight of locomotive equipped, about 28 tons.

The motor cars are six in number, are of the double-truck type, and have the following principal dimensions: length of body, 12.2 m.; width of body, 3.05 m.; distance between centers of trucks, 9.5 m.; wheel base, 2.2 m.; diameter of wheels, 1.02 m., and length over all, 16.3 m. Four 55-h.p. motors are carried on each car, one for each axle. The motors run without load at about 600 r.p.m., and with load at 586 r.p.m. Each motor is equipped with a starting rheostat and controllers similar to those on the locomotives. On the platform are also a hand-brake handle, the triple valve operating the air brake, and above the motorman, about on a level with his head, is a small panel carrying the ampere meters and voltmeter, connected with the 750-volt circuit. Close at hand also are the switch for controlling the motor compressor and pump, and a handle for operating the whistle from the air reservoir. The electrical equipment of the motor cars is similar to that of the locomotives, and includes a 750 100-volt transformer for operating the motor compressor, the lights and the heaters. The motor compressor, its automatic cut-off and the motor fuses are carried in boxes under the cars, and adjoining the body sills.

ELECTRICAL DIAGRAM OF LOCOMOTIVE

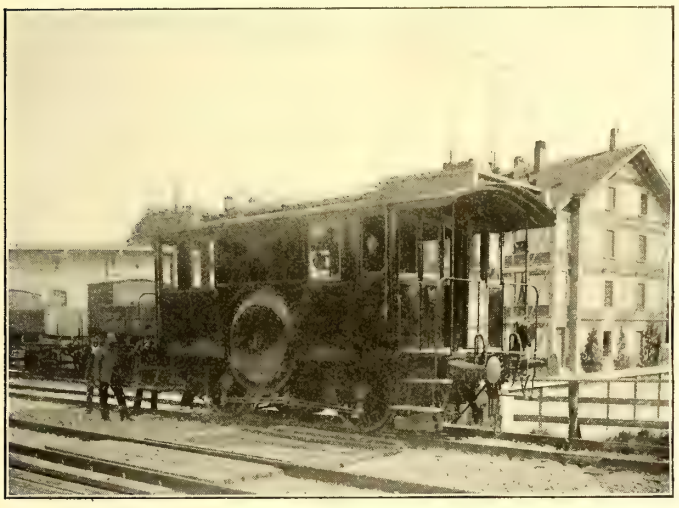
ELECTRICAL DIAGRAM OF MOTOR CAR

To lower the sliding contact bows a short cord is fixed to the upper end of the bow, and connected at its lower end to a short wooden pole, which is normally carried against the side of the car in spring clips. In the middle of the cord is a strain insulator, making it perfectly safe to draw the bow down, even in wet weather. When in a horizontal position the end of the bow catches in a small pawl on the roof, which holds it in position.



The cars have a central aisle, and are divided into four

compartments, of which two are second-class and two third-class, and carry a total of sixty-eight passengers. The weight of the cars fully equipped is 32 tons.



cars, carrying forty passengers, and one two-axle combination passenger, postal and baggage car, carrying twenty passengers. The several engravings herewith show the

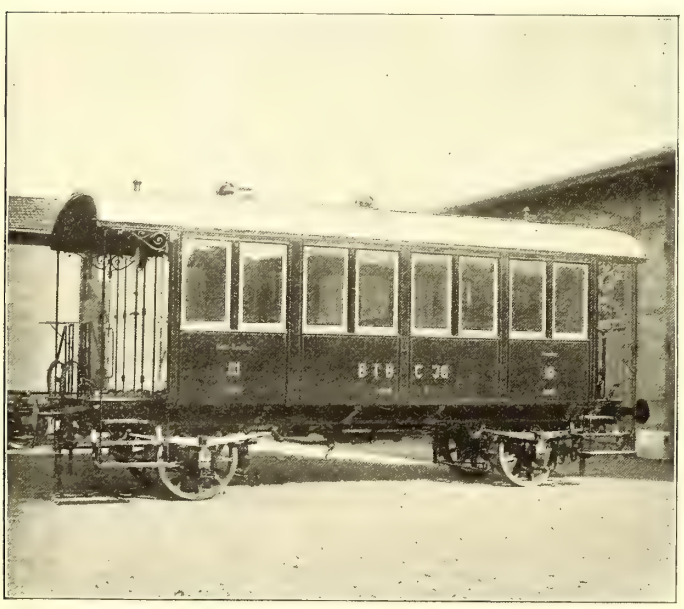
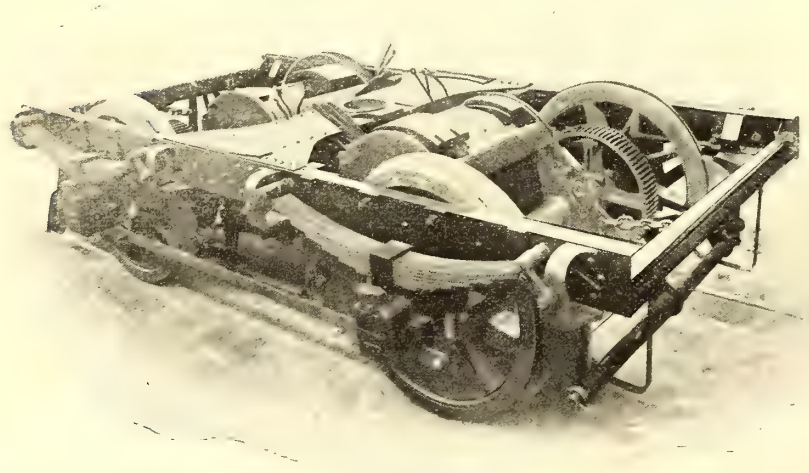
The trail cars are of five different types, as follows: two two-axle cars for second and third-class traffic, carrying fifty-five passengers; two two-axle cars, third-class



different types adopted. A special car for construction work, as well as for the transportation of transformers, is also illustrated.

As the cars are operated on a three-phase system, a constant speed of 36 km. per hour is maintained. The cars



RESISTANCE FOR 60-H.P. MOTOR FOR MOTOR CAR

can be braked quickly, and stop in from three-quarters of a minute to one minute. The train service is conducted by

TRAIL CAR

ordinary steam railroad methods and on the block system. The stations are connected by telegraph, the wires of

STANDARD DOUBLE TRUCK WITH MOTORS

which are carried on the same poles with the trolley wires. Each train consists usually of one motor car and one trail car. If the traffic is too great to be accommodated on these two cars a second motor car is added, because one motor car will not draw more than one trailer. The freight trains operate at 18 km. per hour. In descending grades, the motorman is permitted to let the train speed up to 40 km. for passenger trains and 20 km. for freight trains per hour, when behind time.

Before the opening of the line the system was thoroughly inspected by the federal inspectors, who made tests of the braking system. These seem sufficiently interesting to be reproduced, and are given below.

Train Made Up of	Brakes Applied	Grade in per Cent.	Speed in km. per Hour	Distance Run Before Stop, in Meters
2 motor cars and 1 trail car.	2 hand brakes.	2½	36	100

" " " "	" "	2.1	36	76

The power consumption for starting gave the following results: with one motor car and one trail car, on a 2½ per cent grade and a straight track, the current reached 260 amps. with 760 volts, although on a curve of 250-m. radius and a 2½ per cent grade the same trial took 330 amps. at 850 volts. The maximum consumption of the electric locomotive during the time of trial, with a complete train of 50 tons, at 36 km. per hour, never exceeded 300 amps. at 700 volts. It has been found not advisable to run two trains of cars at the same time in a section fed by one transformer. With two trains, the trains should be six minutes apart, and with three trains of the same size the headway must be about ten minutes.

In conclusion, I will mention the principal contractors. All the electrical apparatus for the railway was furnished by Brown, Boveri & Company, of Baden. The locomotives, so far as the mechanical construction is concerned, were supplied by the Fabrique Suisse pour le Construction de Locomotives, of Winterthur. Finally, the rolling stock was supplied by the Société Industrielle Suisse, of Neuhausen. The turbines at the power station were furnished by Escher, Wyss & Company, of Zurich. The credit of having carried this work through to a successful completion belongs principally to Mr. Dinkelmann, of Burgdorf, a member of the Federal Council and manager of the Ementhalbahn, who gave great personal attention to the construction of this line, of which he is now the manager.

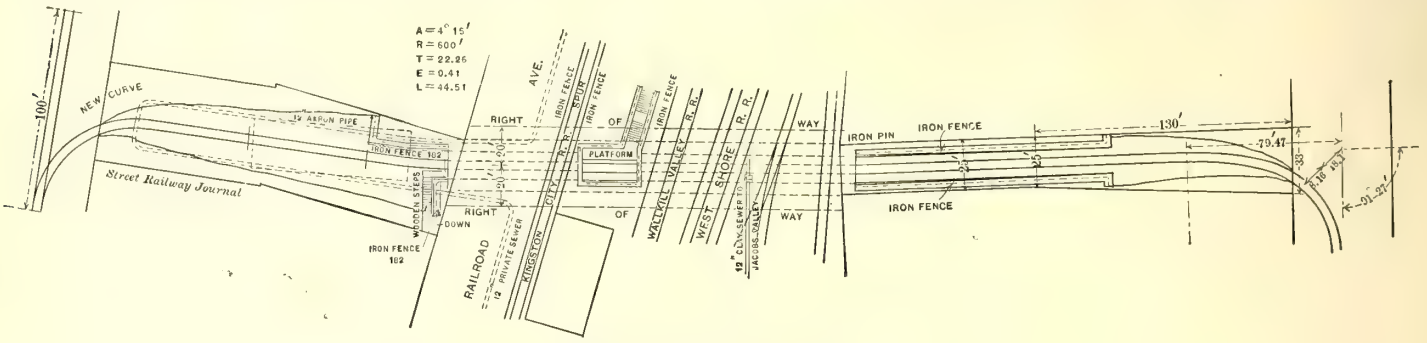
The terminal station of the Staten Island Electric Railroad Company, adjoining the ferry house and station of the Staten Island Ferry and Staten Island Rapid Transit Railroad Company, at St. George, was destroyed by fire Nov. 11. Five cars, which were in the building at the time of the fire, were gotten out without damage.

Subway at Kingston

A very interesting piece of construction work, by which a five-track grade crossing with a steam railroad was avoided, has recently been completed by the Colonial City Traction Company, of Kingston, N. Y. The work is unique so far as is known in the history of small electric railways in the country, for the Colonial City Traction Company owns only fourteen cars, and may be an important suggestion to other companies placed under somewhat similar conditions.

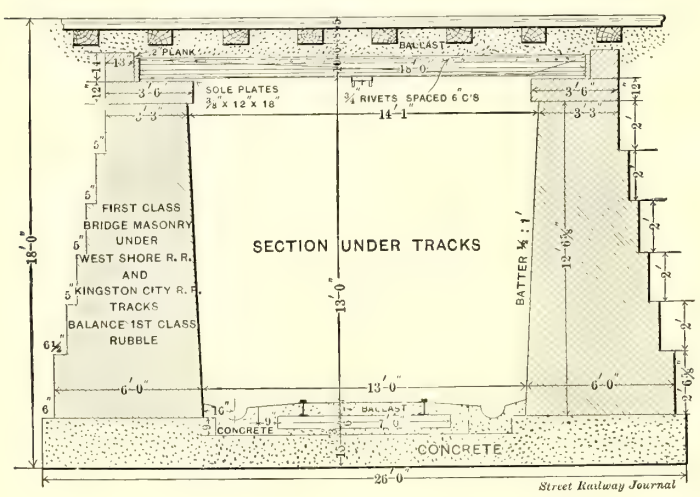
The circumstances which led up to the construction of this subway were as follows: The city of Kingston is intersected by the West Shore Railroad, and possessed up to a few years ago but one railway company, whose line crossed the railroad tracks on grade at right angles. The Colonial City Traction Company was organized as a competing line. Franchises were secured and about two miles of track were built on each side of the city down to the crossing. An effort was then made to secure the right of crossing the West Shore tracks on the tracks of the existing company for a distance of 800 ft., but this was refused by the latter company. The Colonial City Traction Company then (in 1896) went to the Supreme Court for privilege to condemn the right of way over these tracks, and won the suit. The case was appealed, however, by the existing railway company, and carried to the Appellate Division of the Supreme Court, which decided that the consent of the municipal authorities and of the abutting property owners were prerequisites to the action, in this way reversing the decision of the lower court. The question was then carried up by the new company to the Court of Appeals, which sustained the last decision. The Colonial City Traction Company then secured the permission of the authorities, but were unable to obtain that of the property owners. Under these circumstances a request was made to the Appellate Division to appoint commissioners to decide whether the property owners for these 800 ft. were unreasonable in withholding their consents; the commissioners found in favor of the new road. These suits created much interest at the time, as deciding important legal questions, and were commented upon in an extended way in the STREET RAILWAY JOURNAL. During the final litigation, however, a compromise was reached between the two railway companies, by which the Colonial City Traction Company, instead of crossing the West Shore tracks on the tracks of the existing company, agreed to divert its route a short distance to the north, and build a subway under the West Shore tracks, thus connecting its two existing sections.

The covered part of the subway is 220 ft. in length, with approaches of 130 ft. on the east side and 160 ft. on the west side. The sides of the subway under the West Shore Railroad tracks are of first-class bridge masonry, and elsewhere are first-class rubble masonry. The subway station is faced with white enameled brick; the roofing is of open-hearth steel troughs, with a tensile strength of 60,000 lbs. per square inch. The plates and angles composing the troughs of the solid floor system were covered with asphalt, mixed ten parts asphalt and thirty parts coal tar pitch. The bottoms were then filled with a binder composed of ¼-in. clean, sharp gravel and No. 4 asphalt paving composition,

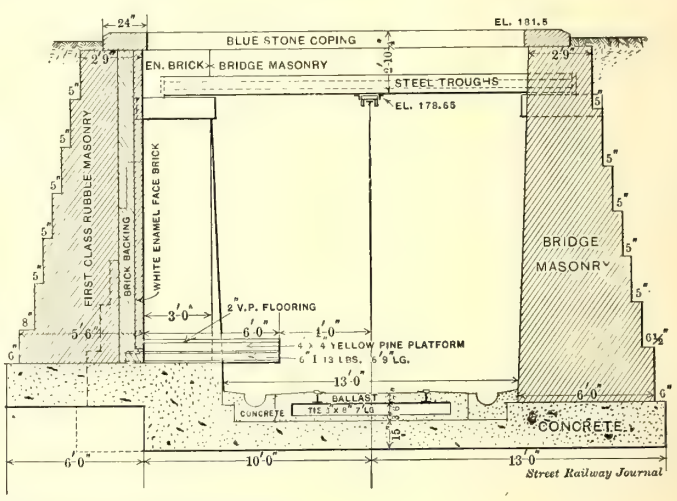


STEPS TO ELECTRIC RAILWAY PLATFORM

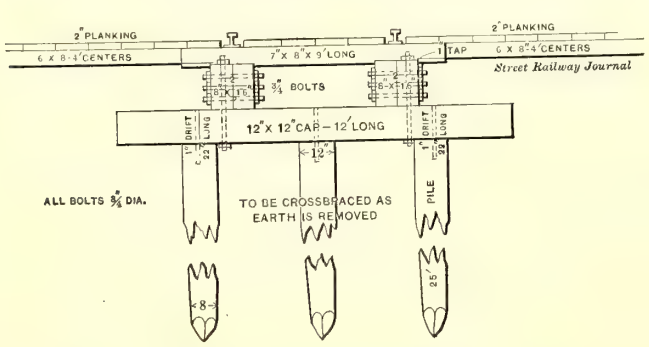
ENTRANCE TO SUBWAY FROM WEST SHORE STATION, KINGSTON



in the proportions of 1 cu. ft. of gravel to 1 gal. of paving composition. There is an entrance to the subway from the platform of the West Shore Railroad Company. This has proved a great convenience to passengers and a means through which the company has added greatly to its traffic, as will be described later. The entrance to the West Shore station is fitted with handsome hand-rails of heavy brass pipe of 2 ins. in diameter, and all stone work is of North River blue stone.



GENERAL PLAN OF SUBWAY



Work on the subway was commenced Aug. 22, 1898, and the first car ran through it on March 19, 1899. The work was carried on without any delay to the traffic on the West Shore Railroad. The method of supporting the tracks on the latter is illustrated on this page. Before any excavation was made within the West Shore right of way a temporary trestle was constructed by driving 25-ft. piles between the tracks. These piles were white oak and not less than 8 ins. on the top and 12 ins. diameter at the butt. After being driven they were capped by 12-in. x 12-in. yellow pine caps, secured to the piles by wrought iron drift pins 1 in. square and 22 ins. long. On these caps were laid the track stringers, which were of yellow pine 8 ins. x 16 ins., and long enough to cover two bents in the trestle. Two stringers were placed under each rail and decked with cross-ties. The entire deck was then covered with 2-in. yellow pine plank, as shown in the sectional view. This supported the tracks while the excavation for the subway was being made.

The method of conducting current to the cars in the subway was another problem, and that first employed is illustrated in section on page 863. It consisted of T iron, 2¼ ins. x 2¼ ins. x 5/16 in. thick, lag-screwed to an 8-in. x 1¾ in. white pine plank, which was held to the roof girders by angles. The plank was protected on the edges by 1-in. x 3-in. timbers, held to the upper plank by wood screws, making a trough to catch the trolley in case it should jump from the conductor. A rubber cushion 3 ins. x 3 ins. x 3/16 in. was used between the conductor and the trough. This construction proved, however, to be too rigid and noisy, in spite of the precautions taken to prevent trouble of this kind, and has since been changed to ordinary trolley wire carried on hangers.

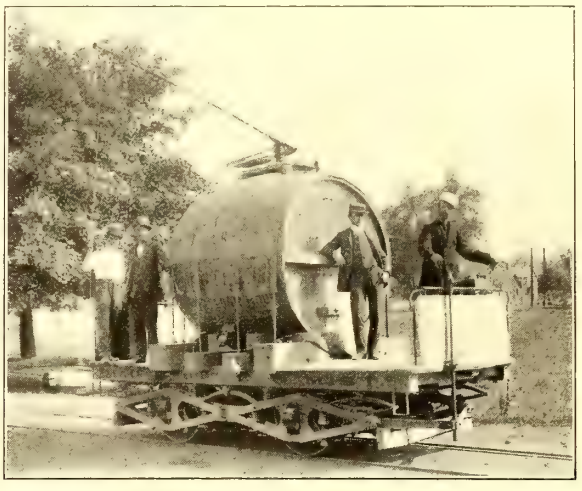
SECTION OF ROOFING

Before the subway was completed and during its construction passengers were transferred from one section of the road to the other, across the West Shore tracks, by bus. The completion of the subway was naturally fol-



lowed by large increase of traffic, partly because the line was now a continuous system and also partly because of its corresponding period a year ago. The entire cost of the subway was about $28,000.

SIDE ELEVATION AND PLAN SHOWING METHOD OF SUPPORTING STEAM RAILROAD TRACKS

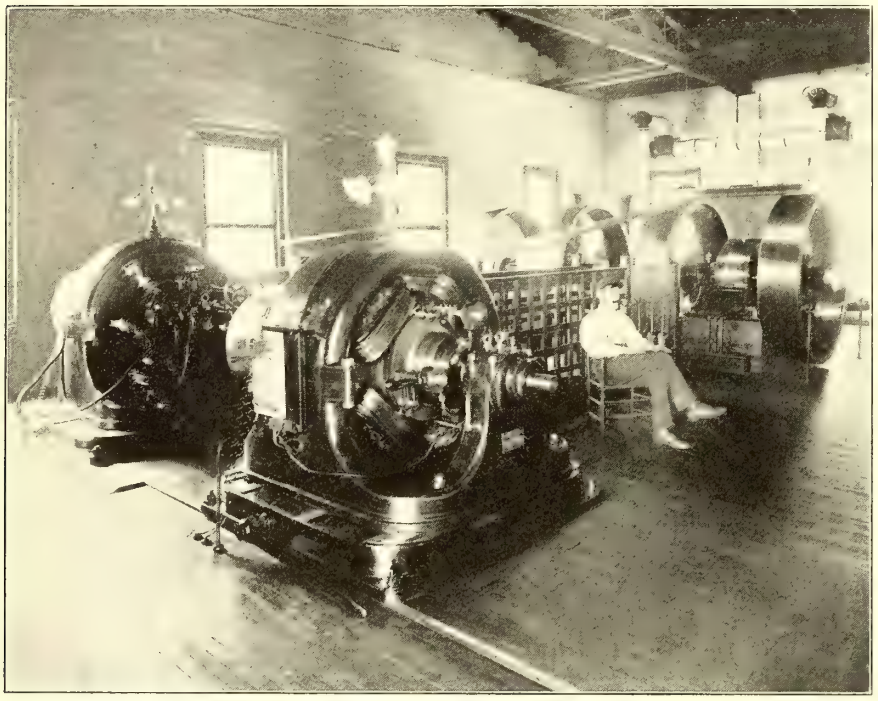
STANDARD 18-FT. CROSS-SEAT CAR



ENTRANCE TO SUBWAY

proximity to the only railway station in the city. As a result, the gross receipts of the company have increased 75 per cent during the past six months, as compared with the

The system of the Colonial City Traction Company has interesting features besides the subway. As Kingston has a population of only about 30,000, and there are two lines

in the city, the keenness of competition makes each company put forth every effort to secure as much traffic as possible. Considerable popularity has been secured by the Colonial City Traction Company through the opening of its subway. Another step to secure traffic was the introduction of cross-seat cars, which have proved very popular. The amount of traffic did not require long cars, so the experiment was tried of using cross seats in an 18-ft. closed car. There are six seats on a side, and a view of one of these cars, which were built by the Pullman Company, is illustrated herewith. The company has in all seven closed and six open cars, mounted on Peckham and Diamond trucks. G. E.-800 motors are used under the former and Westinghouse 49 motors under the latter. The open cars

INTERIOR OF ENGINE ROOM

are of the ten-bench type, and were built by Jackson & Sharp.

Another novelty in car construction is the sprinkler car illustrated. This was gotten up by the superintendent of the company, C. Gordon Reel, at a cost of $65, and consists of a large beer barrel holding 1600 gals., purchased of a local brewer for $10, and mounted on a platform car. The cost of the sprinkler, fittings, etc., which were all home-made, brought the cost up to that stated. In winter this car is fitted with nose plows and used for a snow plow.

The power station is located at the eastern end of the line on the Hudson River, and contains two 150-h.p. Ball & Wood tandem compound condensing engines belted one to a 125-kw. and one to a 150-kw. Westinghouse generators; the two generators are run in parallel. The condensers and pumps are of the Worthington type, and there are two Sterns tubular boilers of 300 h.p. each. Eighty-lb. girder rails are used. The improvements described had an excellent effect on the increase of traffic of the railway.

The road is now in the hands of and operated by a reorganization committee consisting of John I. Waterbury, Chas. M. Preston and August Belmont, with C. Gordon Reel as superintendent. Mr. Reel was formerly connected with the Lindell Railway, of St. Louis, but assumed control of the Kingston road in November, 1896. The receipts have increased 75 per cent during the last year, with an increase in car mileage of 15 per cent and a decrease in operating expenses over 1898 of $6,000 (from $35,000 to $29,000). The cars are now earning about $20 a day on an average of fifteen hours each. The electrician of the company is C. J. McNelis, and Francis Gaffney is the chief engineer of the power station.

Result of Low Fare Experiment on the Chicago General Railway System

The Chicago General Railway Company has been for some time past trying some very interesting graded fare experiments on certain portions of its system. By reference to the colored map of Chicago in the Street Railway Journal for October it will be seen that this company's lines consist of one main stem, running from Wabash Avenue and Twenty-second Street, a distance of about 2 miles from the general postoffice in Chicago, through Twenty-second Street west to Fortieth Avenue, together with a number of comparatively short branch feeders running south from this main stem on Lawndale Avenue, Kedzie Street, Throop and Laurel Streets (to the Union Stock Yards), etc.

A single fare of five cents, with full transfer privileges, is charged on the entire system, or tickets, six for a quarter, are sold with the same privilege. On the branch lines a 2-cent fare without transfer privilege is charged, and twelve tickets are sold for 20 cents. These branch lines are little less than 3 miles in length. Transfer tickets are issued at the time that the fare is paid.

For the first eight months of the present year the Chicago General Railway system was operated on a straight 5-cent fare. The graded fare system has since been in use, and in September and October the gross business showed an increase over the average for the eight previous months of 28 per cent, without materially increased expenses. It is further stated as an interesting fact that on the four lines the company now receives a larger number of 5-cent fares than were taken in before the tickets were sold.

The Berlin Elektricitäts Werke, which supplies current for all the electric railways of Berlin, is the largest electric power company in Europe, and one of the largest in the world. It owns five separate power stations with a total of 43,000 h.p., which will be raised to 61,000 h.p. as soon as the extension, which is now in course of erection, is completed The central stations in the Spandauerstrasse, Mauerstrasse and Schiffbauerdamm form only a part of the electrical supply system. An idea of the total capacity of the system can be obtained from the following table, which gives the maximum capacity of the several stations, all of which are connected together by a net of feeders:

	H.P.	KW.
Central station at Schiffbauerdamm	14,500	9,500
Central station at Spandauerstrasse	11,200	7,400
Central station at Mauerstrasse	9,300	6,100
Central station at Markgrafenstrasse	2,100	1,400
Central station at Oberspree	6,000	4,000
	43,100	28,400

According to these figures the capacity of the Schiffbauerdamm station alone is nearly as great as that of the largest German central station at the present time, and as soon as the 30,000 h.p. additional equipment is installed, the capacity will exceed even that of the power station at Rheinfelden, also installed by the Allgemeine Elektricitäts Gesellschaft.

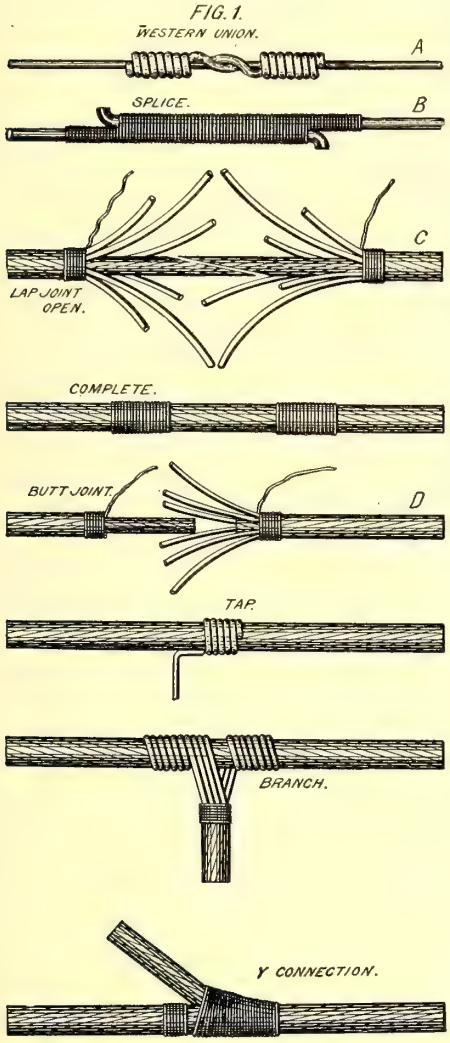
Overhead Line Construction IV

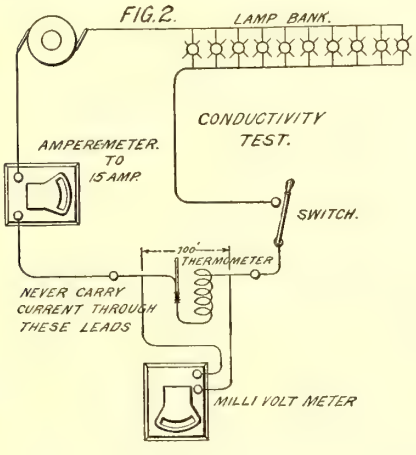
BY ALBERT B. HERRICK

Erecting and Testing Feeders and Setting Poles

It is usual to run two feeders from one circuit breaker in the station to each continuous section, but considerable money can often be saved by combining two feeders into one, giving one equivalent cross section of the two. For instance, 2 miles of triple braided No. 0000 wire weigh 8184 lbs., of which about 1600 lbs. is insulation. If now, a single 450,000 c.m. cable were used instead, it would weigh 8992 lbs., of which only 1000 lbs. is insulation, and the drop of this mile transmission would be lower by 8 per cent than with the two No. 0000 feeders. The tendency in modern line construction is to use larger and fewer feeders, both on the score of line cost, location of weight on pole, and copper economy.

The insulation generally used on wires is known as weatherproof, and it consists of two or three braidings of jute, which should be thoroughly impregnated with a water-proofing compound. The covering and compound should be tough enough to resist considerable abrasion, and there should be no decrease in insulation resistance with 110 volts, after several hours immersion in water.





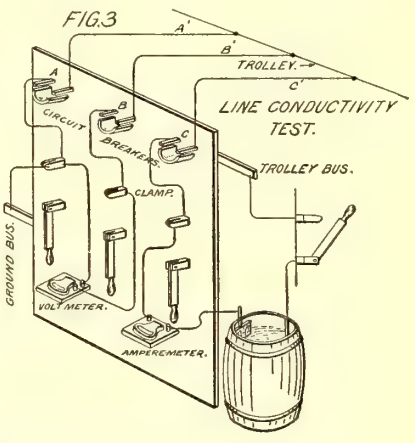


FIG. 1.—METHODS OF MAKING FEEDER JOINTS

It has been the practice in the past to tin the wires of stranded cables. Tinning increases the resistance of the wire, for the tinning combines with the surface copper, and the effect is to slightly reduce the conductivity of the wire. There is no reason for tinning copper where weather-proof covering is used, except where the feeder is exposed to salt sea air, and in mining districts where the air is laden with corrosive gases. Where cables are spliced it is very easy to tin the strands before making the splices.

The ordinary Western Union joint, shown at A in Fig. 1, is satisfactory where the wires are No. 0 or smaller. Good results, however, are not obtained with this joint when the wire is larger than No. 0. The best joint in such cases is made by turning the ends sharply at right angles, paralleling two wires, wrapping with No. 12 copper wire, and then soldering the joint, as shown at B. Solder is usually poured over a joint of this kind, but care should be taken that the wire is hot when the soldering is done. The best way to heat the joint is to use blow lamps, placing the joint on a board. With a little experience the best results may be obtained with resin as a flux, but soldering acids and compounds are generally used. The lap of the two wires on this splice joint should be at least twelve times the diameter of the wire. If properly soldered, this joint will then be as strong as any other part of the cable. Exposed joints should be served with at least four layers of adhesive tape, so that the joint will be as well protected as the insulated wire. A splice in stranded cables is usually made by interweaving the strands of the two cables Several methods often employed are shown at C and D (Fig. 1), but to make the joint electrically satisfactory each wire should be separately tinned before the two cable ends are interlaced. The connection is then served with No. 20 copper wire, as shown.

The conductivity of the copper is of vital importance, of course, and, if desired, it may easily be tested to a fraction of 1 per cent. The necessary instruments are a reliable amperemeter, reading by 50 amps., a millivolt meter, and a thermometer, see Fig. 2. If we produce a flow of 10 amps. through a conductor 100ft. long, the millivolt meter should read 481 millivolts in measuring a No. 0000 wire, or under these conditions each .0001 of an ohm will produce one millivolt deflection, provided the temperature of the wire is 60 degs. F., and the conductor has 100 per cent conductivity of pure copper. In case the temperature of the air is below 60 degs. the thermometer should be placed in contact with the wire, then pass the current through it for a few minutes until the thermometer records slightly above 60 degs., then cut the current off. The thermometer should then be watched until it falls to 60 degs., after which the millivolts drop with current flowing again may be read. To make this method a success, it must be borne in mind that the current should never be carried into the conductor through the contacts taking the drop for the millivolt meter.

FIGS. 2 AND 3.—CONNECTIONS FOR TESTING CONDUCTIVITY OF LINE

As the conductivity of copper changes .00226 for each degree F. the readings for any other temperature of the conductor than 60 degs. F. can be reduced to the standard temperature resistance. We may then divide the standard resistance of the copper by the measured resistance obtained, and thus get the percentage conductivity required. For methods of setting up these tests, see Fig. 2, and for standard resistances see eleventh column of copper table, August issue STREET RAILWAY JOURNAL.

The conductivity test is, of course, useful for the pur-

chase of conductors and to see whether the specifications have been complied with, but the actual line resistance is often of value. The apparatus required for this test is a water barrel rheostat, an ammeter reading about 100 amps., a voltmeter reading about 250 volts, and two connectors that will fit the jaws of a feeder switch and be capable of carrying a load of about 50 amps. The connections are shown in Fig. 3. It will be noticed that the current

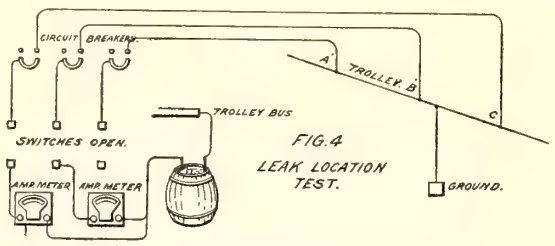

FIG. 4.

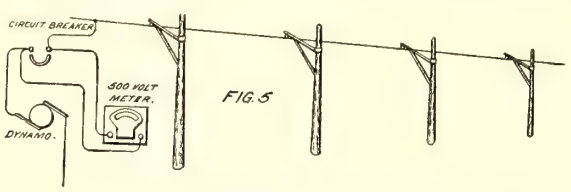
LEAK LOCATION TEST.

FIG. 4.—CONNECTIONS FOR LEAK TEST

passes from the water rheostat through the ammeter, out through feeder C to C', along the trolley line to A', and back to the station to the ground bus through the jaw of switch A. Now, if the voltmeter pressure between A and B and the current flow are known, then the volts divided by the current will give the resistance of the feeder C and



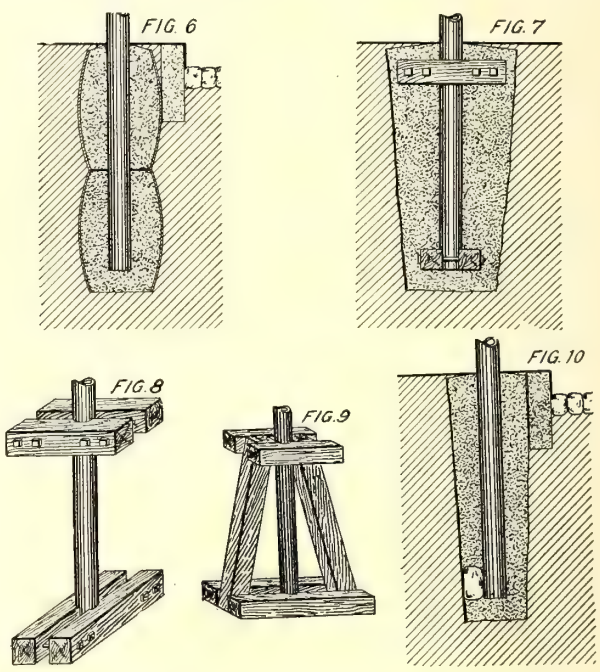


FIG. 5.

FIG. 5.—CONNECTIONS FOR LINE INSULATION TEST

that of the trolley line from C to B. Similarly the pressure between B and C, when divided by the current flow, will give the resistance of the trolley wire from B' to A', and the resistance of feeder A. By shifting the ground bus to the jaw of switch for feeder B, and again putting the load on the system, the volts dropped between A and B, divided by the current flowing, will give the resistance of feeder B. This principle can even be applied to complicated overhead feeder systems which can be temporarily tied together by putting jumpers around the line circuit breakers, and all the electrical data from the overhead line to the power station, can be determined. It is then easy to locate also from the power station grounds or leaks on the line. This requires the use of the water barrel rheostat, the two ammeters and the connections to fit the switch jaws, as in the previous test. The connections used are those shown in Fig. 4. If the leak is considerable, the feeder ammeters will show its approximate location by the irrelative readings, but if the current is slight, low reading ammeters will have to be used.

As an example, supposing it be found that the resistance of feeder A was .15 ohms, that of feeder B .3 ohms, and the trolley wire between A and B .25 ohms; the total resistance of this circuit would then be .7 ohms. It will be noticed that the current can take two paths to the leak, but the resistance of the leak is common to both circuits, consequently the current will pass to this leak through the circuits in the proportion that the resistance of these two circuits bear to each other. Suppose the readings on the two ammeters show that for the circuit A 20 amps. pass, and that for the circuit B 12 amps. pass, the total current flow being 32 amps. Then for A we have the proportion, 32 amps. is to 20 amps., as .7 ohms (the total resistance of the circuit) is to X, (the resistance to the point of leak). For the B circuit we have, 32 is to 12 as .7 is to X. Solving these gives for the circuit through A, .437 ohms, and through B, .2625 ohms. Subtracting the known resistance of B feeder from the resistance of B circuit gives .0125 ohms, from the end of B to the ground, and subtracting from the A circuit the resistance of A feeder (.437—.15) leaves .287 ohms, beyond the end of A feeder to the ground. If we know that the length of the trolley from A to B is (say) 2400 ft. and of uniform cross section, we may divide the resistance of this length by its length, or .3 ohms by 2400 ft., which is equivalent to .000125 per ft. If this resistance per foot is divided into the found resistance from B to ground, or .0125 ohms, we have 102 ft. from B. The same calculation on the A circuit would give 2296 ft., which is the distance from A. Any other leak on the system can be located by removing the ground connection from the ground bus, and applying it to any other feeder terminal with all the feeder switches open. A connection to each independent section will then show if there is a leak.

The practical test for line insulation resistance is to make the test after the line is erected, by the method shown in Fig. 5. Open the station circuit breaker and across the terminals of the open breaker place the leads to a 500 volt

FIGS. 6-10.—METHODS OF SETTING POLES

meter. Of course all circuit breakers feeding in this section must be opened, and all lamp circuits on this section disconnected, otherwise the voltmeter continues to read bus voltage. The voltmeter will show when all circuits are open (this also makes a good method of determining in an unknown system of wiring, which feeders are connected together). When a steady deflection of the voltmeter is obtained on connecting across the open breaker the resistance of the line can be found by multiplying the voltmeter resistance by the bus-bar voltage at the time of making the observation, dividing this product by the volts shown by the voltmeter when connected across the open circuit breaker, and subtracting from this result the voltmeter resistance. It must be remembered that the leakage is that of the total connected system, and not that of the feeder connected.

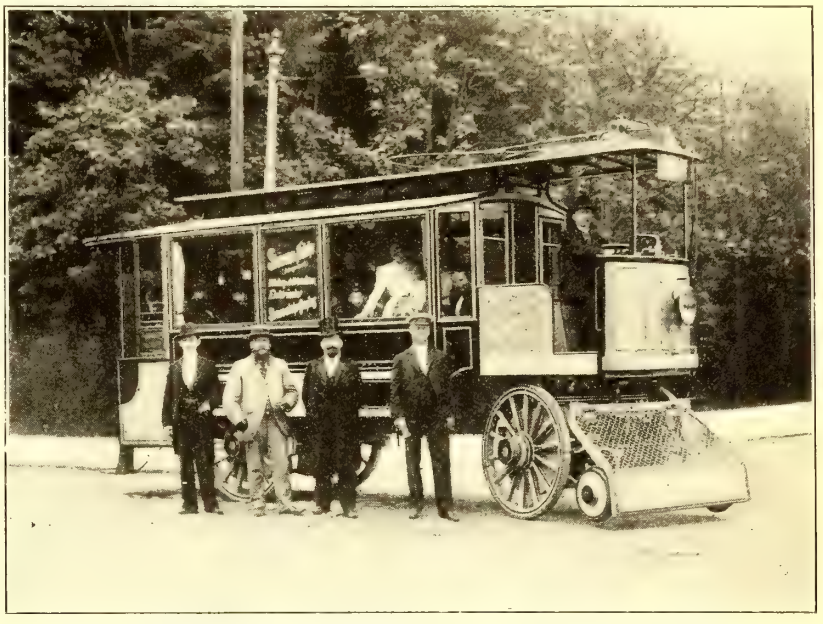
These tests can be made to determine the differences in resistance due to dry, rainy or foggy weather. Tree grounds can also be detected on rainy and windy nights, by the violent variation of the line insulation resistances.

In previous articles we have considered poles, feeder insulators, and feeders, their proper size and character. In

natural order the next question is that of setting the pole. With wooden poles the depth of setting is determined by the line strains, but roughly the pole is set 18 per cent of its length in the ground. For wooden poles the hole should be dug of as small diameter as possible with convenience in digging. In clay ground it should not be larger than 15 ins. at the bottom and 20 ins. at the top. A foot-stone is generally placed at the bottom of the pole on the side opposite from where the strain will fall on the pole. The earth should be well tamped around the pole, and only a few inches of earth should be thrown in at a time. The life of a pole can be considerably prolonged by treating it with creosote. Painting the butt of the pole with pigment, which does not enter the pores of the wood decreases, rather than increases, the life of the pole. Where sandy ground is encountered, such as will not well support a pole, barrels may be buried one upon another, and the pole set in these barrels, as shown in Fig. 6; where iron poles are to be set in concrete in very sandy soils, the same method can also be used.

Poles buried in marshy grounds have to be provided with a structure which will increase their bearing areas; Figs. 7, 8 and 9 show common methods of these constructions. The support of the pole in soft ground has also to be assisted by head guides or brace studs.

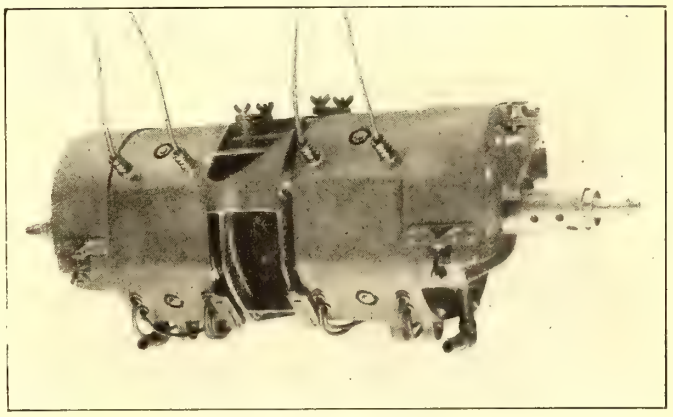
In case of iron poles the surface presented does not give a sufficient bearing area against the soil to carry the strain which the pole is designed to resist, so concrete is used around the base to enlarge the foundation area between the earth and the pole. Fig. 10 shows the standard setting.



The concrete should be composed of one part Portland cement, two parts sharp sand, and four parts broken rock of the size to pass through a 2-in. ring in any direction. The sand and cement should first be thoroughly mixed together while dry, then enough water added to dampen the material and then turned until entirely mixed. The stone is then added and the whole concrete mixed together. Care should be taken that the hole in which the pole is set has fairly smooth sides, so that in tamping the concrete in place, dirt will not be knocked down and mixed with the concrete, and so destroy its usefulness. The setting of iron poles in marshy or loose ground requires about the same special structure as shown in Fig. 6.

Where hard stone is met in a few holes only, and in not sufficient quantity to warrant the use of a steam drill or dynamite, a piece of iron pipe slightly larger than the butt of the pole can be filed with teeth at one end, and by rotating this and feeding with emery and water, the hardest rock can be cut to the depth of 4 ft. in a few hours; the core can then be broken out with a chisel. Where concrete is mixed at one place and carted to the pole line it should be made very wet, and the slow setting variety of cements only should be used. Concrete should always be tamped until a smooth surface shows on the top.

The general standard of street railway employees for faithful service and fidelity to their trust has more than kept pace with the wonderful changes and improvements that rapid transit has brought about, and they will be found vying with their brethren in other pursuits in their devotion to the best interests of their employers.—From address at the Montreal Convention, 1895.



Combined Trolley Car and Omnibus

An exceedingly novel type of vehicle has recently been put in operation in Berlin, Germany, by the Siemens & Halske Aktien-Gesellschaft. The vehicle, as illustrated in the accompanying engraving, possesses the characteristics of both a trolley car and an omnibus. It is in reality an automobile omnibus, fitted with a trolley pole for taking current while running on the railway track and storage batteries, so that it can turn off the track or run in parts of the city where there are no tracks, if desired. It is therefore particularly useful in those cities where the importance of certain streets is such that tracks are not permitted upon them, or where by reason of their narrowness or the enormous traffic in them, the construction upon them of railway tracks is not feasible. The advantage of using the trolley circuit in places is, of course, that the storage battery can be made much lighter than if the omnibus was entirely an electric automobile, that when running on the tracks the traction resistance is less, and also that the batteries can be stored from the trolley circuit during this time, making it unnecessary to change batteries.

COMBINED TROLLEY CAR AND AUTOMOBILE OMNIBUS

To keep the vehicle on the tracks when operating as a trolley car, it is fitted with two guide wheels which run in front of the front driving wheels, and being flanged, keep the regular wheels on the rails. When the vehicle is turned

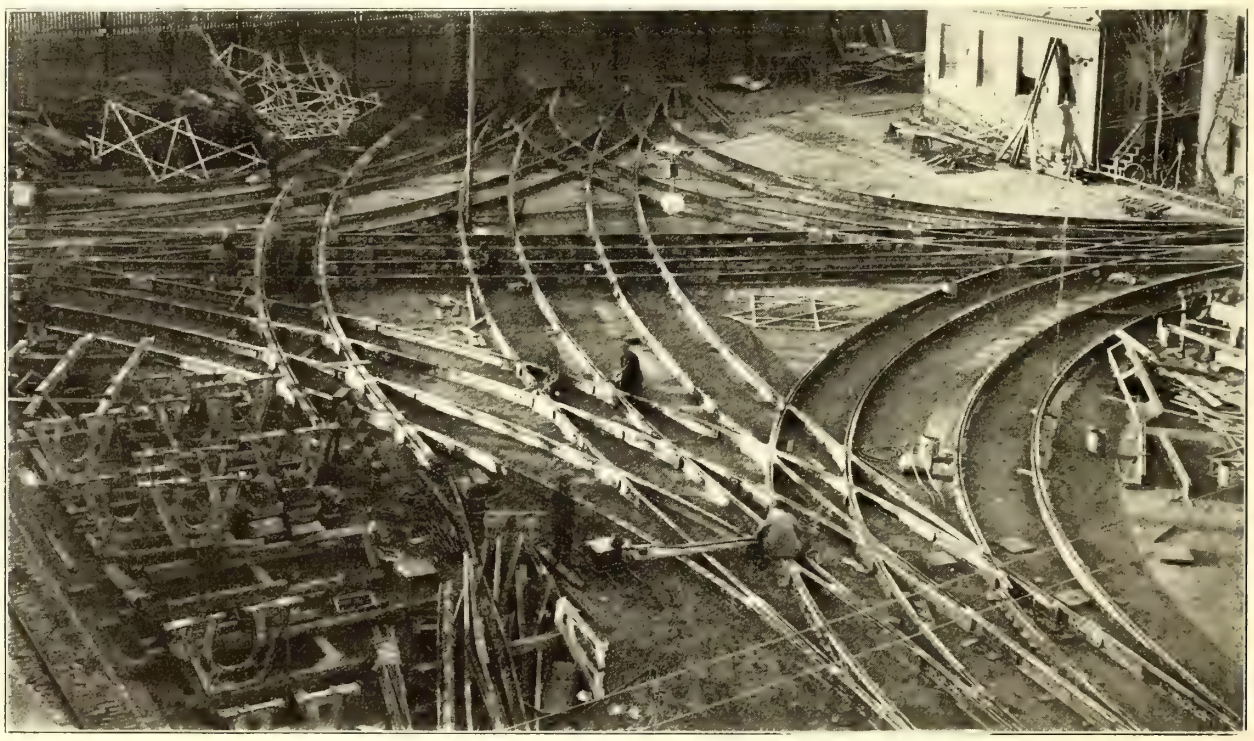
MOTOR FOR OMNIBUS

off the track these guide wheels are raised and the trolley pole is tied down, as shown in the engraving. The car can then be run in any direction desired. In outward appear-

ance, the vehicle differs from a horse omnibus only in that the rail wheels are close together, conforming to the gage of the front wheels, and the latter, to secure greater mobility, are directly under the platform with the motorman.

The usual steering gear is used, but runs in ball bearings, allowing the front truck to be turned at an angle of 90 degs. to the direction of motion. This makes it possible to turn the vehicle in very narrow streets. Ordinary shoe brakes acting on the rear wheels are employed with an electric locking brake on all four wheels for emergency use. Four motors are employed, one for each driving wheel. The motors are 4 h.p. each and are illustrated in the accompanying engraving. The wagon empty weighs 6500 kg. (14,300 lbs.), which is evenly distributed on all four wheels. Of this weight 1500 kg. (3300 lbs.) is that of the storage batteries which consist of 200 cells.

Large Installation of Special Work in Boston



William Wharton, Jr. & Company, of Philadelphia, have recently completed for the Boston Elevated Railway Company the most important piece of track construction ever laid in that city, which is noted for its many and complicated track lay-outs. The installation referred to is that at Dewey Square, and is right in front of the South Boston Terminal steam railroad station. It consists of a double street railroad crossing with two of the tracks on a curve, and both connected with double curves, together with a third track, that shown at the left hand side, which is a freight track used by the Union Freight Railroad Company, and crosses six of the trolley tracks.

All of the curves are provided with spirals on the end, making the engineering work in connection with the lay-out exceedingly difficult and tedious. There are 183 intersecting points of the track lines and the lay-out itself comprises 190 crossings and switch pieces and rails. The design, the steam railroad track being formed of a special crossings for the Union freight track are made of a new very heavy guard rail of the same depth as the girder rail for the street railway track. The intersecting points of the street railway crossing are provided with manganese steel centers, as are, in fact, all of the intersecting parts of the crossing. The weight of material used is about 170 tons.

An especially interesting feature of the work was the promptness with which the order was filled. The entire crossing was manufactured and delivered within ten weeks after the receipt of the order. This time, considering the enormous size of the lay-out and the state of the iron market, is certainly remarkable. The material for the lay-out had to be transported on seven railroad cars of large capacity, and by special arrangement this train of cars was rushed through Boston, reaching there in two days, in spite of the immense accumulation of cars and freight blockade now existing in Jersey City. It was taken in hand at once by the engineers of the Boston Elevated Railroad. Work was commenced on Saturday, Nov. 18, and by the following Tuesday the entire lay-out was practically down and finished and cars running over it.

Another interesting feature of the installation is that in spite of its size it was all laid down complete in the works of the Wharton Company before shipment, every piece being in its place.

The contract price is said to have been in round numbers $15,000. This low price was secured by contract last February before the recent rise in the steel market, otherwise the cost would have been considerably higher.

LARGE PIECE OF SPECIAL WORK AT DEWEY SQUARE, BOSTON

Street Railways in Para

In a recent letter from a friend in Para, Brazil, he says: "This is a city of from 125,000 to 150,000 people, and is growing very rapidly. It has a street car system which threads the city in every direction, and it is patronized to perfection, almost every one being willing to wait fifteen or twenty minutes for a tram car in preference to walking. The equipment is, however, unmentionable. The little mules can fairly fly down hill, but up grade they are always in trouble with the heavy loads they have to haul. There is a great opportunity for the spare capital and spare engineers of the United States to come down here and put in an electric system. Please send them down, and the sooner the better."

Interview With John A. Brill on Foreign Practice in Rolling Stock

John A. Brill, vice-president of the J. G. Brill Company, of Philadelphia, returned to this country last month from a trip to Europe. A representative of the STREET RAILWAY JOURNAL called upon him, shortly after his arrival, and in response to questions obtained some very interesting information in regard to European practice in rolling stock, and the reasons which have led up to the large export movement from America in tramway rolling stock.

Mr. Brill was first asked whether as much electric railway construction projected abroad as in the United States, that is, whether the business is opening up largely at the present time.

In reply, he said: "The countries of Europe are in about the same condition that this country was six or eight years ago, that is as far as the urban railways are concerned. As yet there has been little done in interurban lines. The development is likely to be more rapid in European countries than in the United States, owing to the greater density of the population and the greater amount of wealth which can be used for the building of roads, and no doubt urban, suburban and interurban electric railroading will become as important an industry in Europe as in America."

"What countries are taking up this matter most vigorously?"

"Up to the present time Germany has completed the most electric railways, with France second and Great Britain third. There is considerable now being done in Italy, which is probably a good fourth. The other European countries straggle far in the rear, with the exception of little Belgium, which has done considerable for its size."

"In what countries do you think there is the best field; that is, what countries possess the best local conditions?"

"This has been probably answered by the foregoing, as the qualifications of the respective countries have placed them in the above mentioned order. The local conditions of none of the European countries are quite as good as they are here, so far as the local aspect is concerned, for the reason that in all European countries there are greater or less restrictions and difficulties, first as regards charter rights, second as regards the quality of work done, and lastly, which is probably the greatest obstacle, the restricted width of cars, together with the limitations as to loads and other details of operation. In many of the larger cities the speed limit hampers the profitable operation of a road and has brought the mileage down, in some cases, as low as ordinary horse travel. There is a scheme proposed now in England that the Board of Trade, which controls all of the tramways, shall compel them to equip their cars with a speed meter which will show the rate of speed, and will be inspected from time to time while the cars are in operation by men appointed for the purpose. I understand that the authorities of the city of Dover, Eng., have placed a speed restriction of 4½ miles per hour in the center of the city. These restrictions are so foreign to what exist in the United States that to an American railroad man they seem greatly to handicap the operation."

"Is the electric railway work abroad being done under municipal or private ownership?"

"In Great Britain the majority of the roads are under municipal ownership, as in Liverpool, Leeds, Hull, Southampton and Glasgow. On the Continent they are very largely under private ownership."

"In what respects does European and English practice in rolling stock differ from that of this country, especially in such features as length, width, height, seating capacity, length of platforms, single and double-deck cars, California types, etc.?"

"The practice differs in many respects. In England, at the present time, the double-deck car has largely the 'call,' and although a few single-deck cars are being ordered, they are very few as yet, and are greatly in the minority. The universal practice in Europe is to restrict the load of the car to the number of passengers that can be seated, except that a certain number of persons are allowed to stand on the platforms, which number is always specified by a sign on the car. In consequence, the disposition is to get very large platforms; in some cases they are as long as 6 ft., which allows standing room for nine persons. This length is 50 per cent greater than the practice in America. As regards the length of cars on the other side, they do not as yet appreciate the advantage of large units as we do in this country. The great majority of the cars are of the four-wheel type and in very few instances longer than 18 ft. in body, which gives a seating capacity for twenty-four people."

"What are the conditions which lead to the differences in types?"

"In France the double-deck car is largely in demand for the reason that the outside seats are for second class passengers and the inside for first class passengers. In Paris the rate of fare for outside passengers is one-half of that for the inside. In England the reason for the large demand and use of double-deck cars is because many people prefer the outside seats where they can smoke and get the fresh air. Open cars are very little used on account of the width restrictions and the briefness of their hot season. I think that these conditions are likely to continue."

"Is it probable that ultimately different standard types will be developed for French, English and German Railways?"

"Everything indicates, to my mind, that they will ultimately fall into the American types, which are certainly in the lead, and of the double-truck class."

"In the matter of brakes and wheels, what are the peculiarities of European practice and what are the prospects for the future of cast-iron wheels as they are used in this country?"

"As regards wheels, when we first began to ship trucks abroad our customers almost invariably demanded a steel-tired wheel with wrought-iron centers; later on we were allowed to put in cast-iron centers, and now about 75 per cent of our orders call for chilled-iron wheels. This, I think, is largely due to the fact that they have found that the chilled-iron wheels, when made with proper flanges, have given very good satisfaction. In conversation a short time ago with one of the employees of the Liverpool Corporation Tramways, I was informed that the wheels that we had furnished on a lot of cars had already made 24,000 miles, were in very good condition and looked as if they would make at least 16,000 miles more. Considering the additional wear engendered by the narrow-grooved rails, this is very good service. It might be well for me to say here that to P. H. Griffin, of the New York Car Wheel Company, is due very largely the fact that American chilled-iron wheels are now looked upon with favor. He has personally studied the subject on the ground and his agents have carefully looked into any complaints which have been made and rectified such troubles as have been called to their notice, and as a consequence we have many calls for wheels of this make. As regards brakes, the conditions are nearly the same there as they are in this country, although it is quite an interesting item historically that on a lot of trucks which we built for Rome, Italy, the authorities required that cars riding on the Seven Hills

should be fitted with the extra precaution of track brakes, in addition to the wheel brakes. I found that air brakes were used more extensively in Germany than anywhere else in Europe, and that they were of the Standard Air Brake Company's type with the axle-driven compressor, which is rather remarkable considering the fact that the axle-driven compressor is not at all in favor in this country."

"Will the high rate of speed and the long distances between their stops enable European roads to use steel-tired wheels with economy?"

"In answer to this question I would say positively, no, because I am a firm believer in the American chilled-iron wheel, as regards the economy of their use over steel-tired wheels. Steel-tired wheels, if used on T rails and well up out of the dirt and dust of the highway, will probably prove more economical than on an ordinary street railway track, but if used on the ordinary street railway track, in competition with the cast-iron wheel, there is more abrasion from the dust and grit, from the fact that their composition is much softer and more easily worn away than the chilled-iron rims."

When asked about the use of heaters abroad, Mr. Brill said: "We have not had electric heaters in the specifications of any of the cars that we have built for Europe, and I do not recollect seeing them in any of the cars in the European countries. Naturally, they must come into use in countries where the climate is sufficiently cold to call for a heater."

"Is there a favorable prospect for the introduction of American registers on European roads?"

"No, I do not see that there can be much of a field for American registers on European roads for the reason of the multiplicity of fares. At the present time the system mostly in vogue is the ticket system, which compels the conductor to give each passenger a ticket recording the amount of fare he has paid and the destination, and at regular stations along the road are inspectors who are supposed to look at them. In other places they have the bell punch system."

"How do foreign built cars compare with those built in this country in weight, cost, durability, style, etc.?"

"With the exception of the products of one or two manufacturers, the foreign built cars do not compare favorably with the American cars in the cost of construction, which is somewhat less than the transportation together with the duties taken into consideration. They keep their prices just low enough to meet these two items, so that the price is rather a high wall or bar to the selling of many cars in European countries. As regards the weight of European cars compared with that of American cars, I think that there is very little difference, as the American builders have been gradually increasing the weight of their cars to a considerable extent within the past few years owing to the increased speed, and I really think that we have arrived at a point now where our cars are heavier than European cars, because of the demand occasioned by the increased speed and loads. As regards the durability and style, I do not think the foreign builders approach us. There are a number of things that the best American builders do, that are recognized as good practice, to increase the strength of their cars without adding additional material, which as yet the European builders have not followed. As to the style and finish, there is absolutely no comparison between the average European car and the average American car. It is all in favor of the American car, notwithstanding the fact that European builders are living in the atmosphere of the old masters and high art and we are surrounded by the crudities of a new country."

"Are the German builders likely to be successful in building cars in which iron largely takes the place of wood?"

"I do not know that the Germans use iron largely in place of wood, with the exception of the panels. These are made of sheet-steel instead of thin poplar. As regards the under construction of a car, that is, the bottom framing, I think that we use about as much iron as they do."

"Is there any information available in regard to the kinds of woods used in England and on the Continent for car building?"

"They are following the American practice in this direction to a great extent and are using American lumber the same as the American car builders do, that is, oak, yellow pine and ash; but for the interior finish I find that in Germany and in France they are using a much cheaper grade of wood than we are, largely yellow pine, and they are not as careful of the selection as we are. It is not an uncommon thing to see knots of good size both in the panels and in the rails."

"Are foreigners building reasonably successful types of trucks, and what types are they employing?"

"This is rather a delicate question for me to answer, because I think that not only are the foreign builders, but that many of the American builders as well, are far from making such successful trucks as are made by my company. In the first place, the foreigners, like the American builders of trucks, are making a composite truck with numerous rivets, bolts, etc., which, when operated or shown beside our solid wrought-forged truck, makes a very poor comparison."

"Has the recent exportation of cars from America been due principally to our natural advantages in climate, material and workmanship, or simply to the fact that we have the plants and experience and can turn out the material cheaper and better than foreign countries; in other words, is the export movement a permanent one, or will it decrease with the increase of electric railway business abroad?"

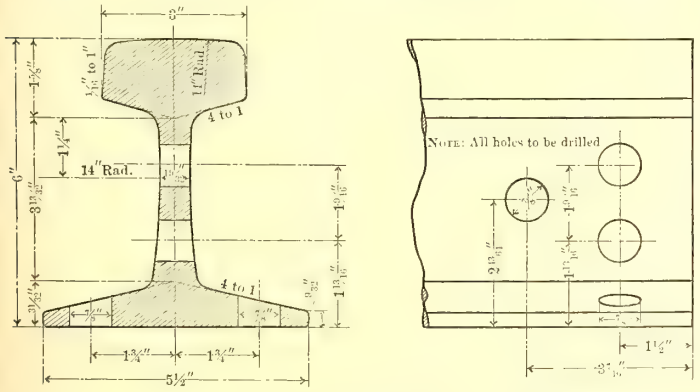
"Unquestionably, it is due to the natural resources of America and the established factories for the construction of cars, but while we do make them better than those made in foreign countries, we do not make them cheaper, and it seems to me that it is only a question of time when this export movement will fall off."

In conclusion, Mr. Brill was asked how the foreign methods of business in the matter of credits, terms of payment, etc., compare with those of America?

He said: "This question embodies a little more than you have distinctly stated, probably your intention is to ascertain my opinion of the desirability of foreign business. The foreign business involves considerably more outlay at the factory in material and time for the same number of cars and trucks than does the American, for the reason that all of the cars must be taken apart and boxed in sections or boxed whole, and the same treatment is given to the trucks, which makes a delay in the output which is not met with in work for America. In addition to this, the shipping facilities for such bulky articles are so meagre that it is quite difficult to get, on the northern seaboard of the United States, transportation for a large quantity of tram cars unless the shipment is spread out for a considerable length of time. At the same time there are incidental expenses attending foreign sales which add greatly to the cost; I refer to the matter of frequent and costly cablegrams, and to the very much greater cost of selling there either direct or through local agents. The great wealth of European countries and the great competition for business has led to the giving of very long credits, and in many

cases the companies hold back a percentage for a period anywhere from twelve to twenty-four months to insure first-class work, so, ordinarily, the terms of payment are not as satisfactory nor as favorable as in this country. Again, the handling of cars and trucks for foreign account seriously interferes with the total output or capacity of a factory.

New Elevated Railway in Berlin



Trial trips are now being made with the first two cars on the Berlin electric elevated road. They were constructed by the firm van der Lypen & Charlier of Koln-Dentz, according to entirely new designs, and were kept for some time at the experimental station of Siemens & Halske in Gross-Lichterfelde. In exterior and interior finish the cars resemble those of the Prussian State roads, and the private imperial cars.

The two cars now in operation are motor cars, and one will be in front and one in the rear of each electric elevated train, with two trailers between them. Such a motor car is 11 meters in length, 2.3 meters in width, and is 3 meters high. It has a seating capacity for thirty-six persons, and a total weight of twenty-one tons. The two ends are fitted with semi-circular plate glass windows, by means of which the air pressure against the platforms is somewhat reduced.

The Berlin public, however, seems to be much dissatisfied with the appearance of the elevated road which is now in course of construction. The taxpayers, particularly in the West End of Berlin and Charlottenburg, demand that the still unfinished portion be built underground, which the builders refuse to do on account of the increased cost. Where the road passes the new Kaiser-Wilhelm Memorial Church, built at a cost of 10,000,000 marks, it has, however, been decided to use sandstone in the construction instead of steel. Two more years will probably be required before the road will be opened to the public.

Third Rail for Manhattan Elevated Railway

The third rail for the Manhattan Elevated Railroad Company's electrical equipment has been selected and is shown herewith in section and side elevation. It weighs 100 lbs. to the yard and will be supplied by the Lackawanna Steel Company. The rail ends are being drilled for two kinds of bonding, through the web and through each side of the base. The contract for bonds has not yet been awarded.

THIRD RAIL FOR MANHATTAN RAILWAY

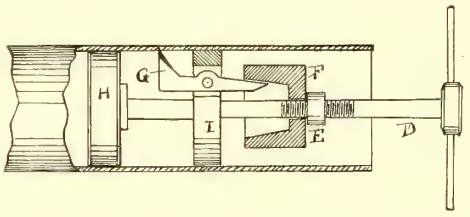
The Boston Elevated Railway Company has a man in its employ who wears eight service stripes, denoting forty years of service with the company. This is undoubtedly a record.

CORRESPONDENCE

Arrangement of Swing Runs

DETROIT, Nov. 25, 1899.

EDITORS STREET RAILWAY JOURNAL:



I notice in the proceedings of the American Street Railway Convention, at Chicago, one speaker advocated shorter hours for employees. I believe he was right, and particularly so in the case of swing runs, that now require work for twelve hours or more, that is until 12 o'clock to 1 o'clock at night, and beginning again anywhere from 5 A. M. to 6 A. M. I believe ten hours work would be very much better for both the company and workman. In all cases where a man is over-worked and his rest and sleep broken he is very apt to be cross, to pay less attention to business, and not be so polite and civil as when he is refreshed and well rested. If the time tables were so arranged that the last cars in were the last ones out, and ten hours constituted a day's work, except under extraordinary conditions, the company, men and the public would be better served. A. CARR.

Pipe Thread Cutting

BOSTON, Mass., Nov. 10, 1899.

EDITORS STREET RAILWAY JOURNAL:

It is often necessary to cut an inside pipe thread in repair shop work, and for doing this I have found the home-made cutter, illustrated below, exceedingly handy. The parts are mounted on a shaft *(D)* which turns in a disc *(I)*, which fits in the pipe as shown. A head having radial slots

is fitted on the shaft at *(F)* to turn with it, the levers carrying the cutter *(G)* being pivoted at *(I)* and operated by the head. This head piece is conical in shape and when moved forward by means of the nut *(E)* is made to expand the cutting tool and cut the interior of the pipe shell as the cutter is turned by a crank keyed on the end of the shaft to turn it. The inner end of the shaft is kept straight by the cylindrical piece *(H)*. F.

Special observation of the interior of the cars will show that the varnish commences to disappear first around the sash—moisture from the windows gathering around the molding which holds the window sash, first discoloring it and gradually working into the sash itself. A car cleaner which is made up largely of oil and dryer, if used about once a week on the window sash and molding, will be found to be a great advantage. From paper at the Boston Convention, 1898.

In the selection of designs for painting of cars, the plainest and neatest design should be selected as a rule. No lettering should be done on the panels, as this increases greatly the cost of maintenance in the paint shop department. In all cases the signs should be put upon sign boards made especially for the purpose. From paper at the Boston Convention, 1898.

STREET RAILWAY JOURNAL

DECEMBER, 1899.

TERMS OF SUBSCRIPTION.

In the United States and Canada..... $4.00 per annum.
In all Foreign Countries, per annum..... $6.00 / 25/ / 31 fr

Subscriptions payable always in advance, by check (preferred), money order or postal note, to order of C. E. WHITTLESEY, Treasurer.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

In a recent communication to the "Electrical World and Engineer" John Lundie suggests a new method of power rating for electric railway motors, which will be most valuable to engineers as a basis for specifications. Mr. Lundie proposes to rate railway, and other motors intended for intermittent service, on the basis of the *average* electrical input in kilowatts which the motor can take care of within the commutation limits, and with a given maximum temperature difference above the surrounding atmosphere. A 30-kw. motor, for example, would be one which would, at 500 volts pressure, take without excessive heating 60 amps. of continuous load, 100 amps. for 60 per cent of the time, 250 amps. for 24 per cent of the time, etc., the maximum limit being determined generally by commutation. In other words, Mr. Lundie claims that, with a well designed motor, however much the current may vary, the sum of the percentages to total input of the C^2 R and core losses can be made to be nearly a constant at all inputs throughout the range of practical operation. The correctness of this theory is challenged editorially by the "Electrical World and Engineer," which states that the sum of a constant and square function cannot be a first-power function, overlooking the fact that the second power of C disappears when the *percentage* losses are considered, i. e., $\frac{C^2 R}{C} = CR$, a first-power function. In his reply Mr. Lundie points this out, and also states a fact shown by examination of many motor curves, that the sum of the percentages of copper and iron losses through a range of from 40 amps. to 200 amps. does not vary 2 per cent, and that in one of the best motors ever built the efficiency is practically a constant within working limits. He believes that this is an ideal to be aimed at in designing motors intended for intermittent fluctuating work, and under these conditions the proposed method of railway motor rating completely applies. The convenience of this method is very great, and even if there should be slight variations from exactness it would seem that results would be quite close enough for commercial use—certainly much better than obtained by the present methods of rating. Motors may be thus most easily tested in regular service to see if they comply with specifications, the process simply consisting of taking volt and ammeter readings in regular service of car, together with final temperature of coils after one or more hours' service. Moreover, with a knowledge of the average power requirements of motors on a given railway line, the rated power of motors to be specified immediately appears, though the maximum and minimum operating currents ought also to be specified.

Two novel methods of foreign practice in electric railway construction are described at considerable length in this issue, one a side slot conduit recently installed at Paris, and the most important conduit line in that city; the other the Burgdorf-Thun three-phase electric railway in Switzerland, the longest and most important three-phase electric railway in the world. Both differ so much from American engineering practice that considerable space has been devoted in this issue to their description. This does not necessarily mean that we believe that the methods followed will obtain wide adoption in this country, but being on entirely new lines they will undoubtedly suggest certain points which can perhaps be utilized to advantage, and as they represent the best engineering practice in these directions in the countries in which the installations have been made, they are undoubtedly of great interest. The side slot conduit in Paris is avowedly patterned in most particulars after that of the Metropolitan Railroad Company, of Washington, with the exception of the position of the conduit, and was, in fact, installed by the same engineer, Mr. Connett. The use of the side slot was obligatory, but as Mr. Connett points out, has a number of disadvantages as compared with the center slot conduit. These are practically insurmountable at switches, so much so, that the conduit had to be diverted to the center of the track at these points. Even under these conditions the necessary width of the slot would, to American eyes, make the system impracticable in American cities. The width of slot admitted by the authorities in some of the foreign cities seems to us almost incomprehensible when we consider that in New York, Chicago and elsewhere, where cable and electric conduits are used, the slot rails form a favorite path for bicyclers, while in Buda-Pest, for example, a bicycle wheel with even a $1\frac{1}{2}$-in. tire would pass through the slot without

difficulty. The slot in Paris is only 1 in., but this is considerably wider than New York or Washington practice.

* * *

The three-phase railway seems to be peculiar to Switzerland. Of the four roads which have been built, in which three-phase motors are employed, three have been within the boundaries of that country, and the fourth, that at Lugano, is practically so, being but a few miles beyond the boundary, in Italy. The reason for this fact is that all of the pioneer work in this direction has been carried on by Brown, Boveri & Company, and they should receive the credit for undertaking this advance work at a time when the proposition was looked at askance by other builders. While the alternating system possesses certain advantages it is noticeable that American practice limits the use of the alternating current to the distribution system. There are plenty of railways in this country with operating conditions very similar to the Burgdorf-Thun line described elsewhere, and others are projected, but in every case where the current is distributed at high potentials, rotaries are used for rectifying the current and reducing it to the standard railway voltage before placing it on the trolley wire. Of course, one more conversion is required, and the economy of the entire system is reduced by the loss in the rotaries; on the other hand it is thought here that the practical benefit is more than made up by the convenience afforded in a simplified overhead system, a more flexible control of the motor speeds, and finally, and most important of all, in the ability to use standard railway apparatus. While the electric motor of to-day may be far from perfect, its ailments and weaknesses are thoroughly understood, and can be guarded against or the apparatus repaired in case of disaster, by men who have gained their experience on any of the existing electric roads. Again, practically every high-speed road which has been built or is projected in this country, runs into some large city over existing city tracks, and as this condition is likely to continue, railway managers would not regard with much favor a proposition to employ one electric system and kind of motors for suburban service, and another for city service, so that, until alternating current engineers are ready to supply an alternating current railway motor and system which would be more desirable for city service than the present direct current motor and distribution system, we do not look for any extended use of three-phase work on interurban railways outside of distribution circuits.

Will the Proposed Underground Railway in New York Pay?

With all legal obstacles removed, the Board of Rapid Transit Commissioners of the City of New York has issued invitations for bids upon the proposed rapid transit tunnel railway. This railway is to run through a 50-ft., four-track tunnel from a southern (loop) terminal at City Hall Park, north to the Grand Central Station on Forty-second Street, thence west a short distance to Broadway, and thence north through upper Broadway (formerly the Boulevard) to Ninety-seventh Street. From this point two double-track branches will run, one, by combined tunnel and viaduct, north on the west side of the city to a point above 230th Street on Washington Heights, and the other, by tunnel and viaduct, east and north on the east side of the city to Bronx Park.

In laying out this route the Rapid Transit Board has evidently, and perhaps quite rightly, had in mind the upbuilding of the city rather than the construction of an immediately profitable transportation system. In other words, it is proposed to build a "real estate road" on a large scale. For many years past, upper Broadway, or the Boulevard, has been in a languishing condition, and a great disappointment to over-enthusiastic real estate speculators. The upper West Side, which the Boulevard nearly bisects, has been given over almost entirely to the better class of residences, and business interests have been confined to the supply of local trade requirements. Real estate in the "Annexed District" above the Harlem, now to be served by the East Side line, has also been "quiet" through lack of adequate transportation facilities. Unquestionably the new rapid transit railway will, if built in its entirety, add enormously to property valuations along and nearby its routes, and will be of great benefit to the city.

The questions which capital will have to face in acting upon the invitation of the city to build this tunnel are, however, of a different order. It is true that a syndicate may be formed which shall combine the functions of building and operating this railway with those of investment in real estate in this district which the railway is to serve, and such a syndicate may hope to reap either a triple profit, or a profit from the real estate ventures large enough to wipe out possible losses from the building and operation of the railway. Primarily, however, it is certainly desirable that the railway shall be at least self supporting from the start, and shall eventually, through the seventy-five-year lease which the city offers to the constructors, become profitable in an increasing ratio. What are the chances that this may be done?

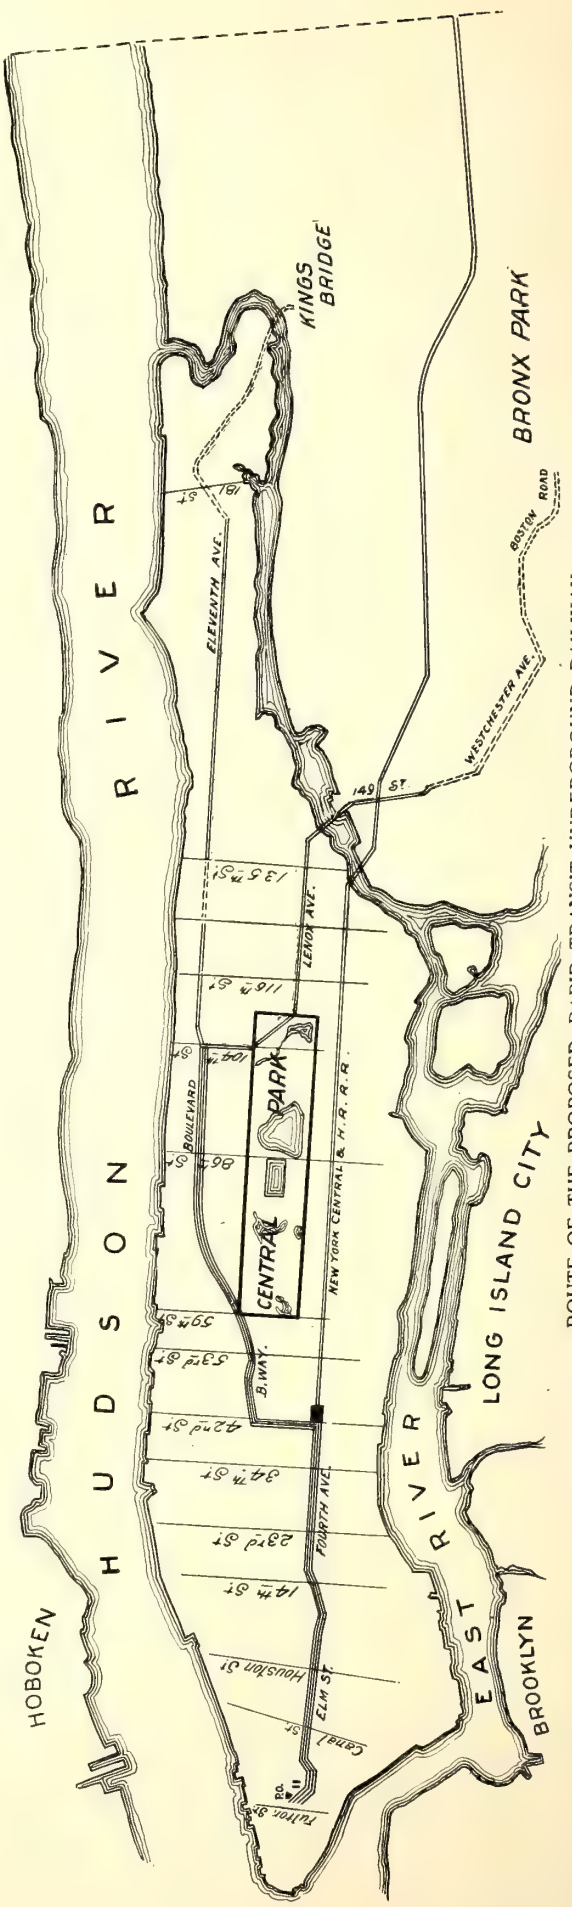
The entire route is divided into four sections. Section I. comprises the portion below Fifty-ninth Street; section II. the portion north of Fifty-ninth Street to 137th Street on the West Side, and from Ninety-seventh Street to 135th Street on the East Side; section III., the portion north of 137th Street to Fort George on the West Side, and north from 135th Street to Melrose Avenue on the East Side; and section IV., the portion north of Fort George on the West Side, and north of Melrose Avenue on the East Side.

The city, being desirous of limiting its total liability, proposes to reserve by contract, the right to determine whether sections II., III. and IV., either or all, shall, or shall not be built. The bidders, now necessarily ignorant of the city's decisions, which may be made one, two or three years hence, are expected, therefore, to see a profit in the construction and operation of section I. alone, and of the entire road. Otherwise they cannot bid with safety on the present specifications and proposed contract.

They must, therefore, first face the problem: Will section I. alone be profitable?

We have no doubt whatever upon this point—it will never be profitable to operate this section alone until the time comes when both surface and elevated cars operating in the lower end of the city shall be so overcrowded that passengers are absolutely forced, in self-defense, to take the underground as a third alternative route.

Consider the situation. The lower end of Manhattan Island, from Fifty-ninth Street to the Battery, is but 5



miles north and south, and 2 miles wide at the widest portion. While there is still a large residential population in this territory, it is being steadily crowded northward out of the district by the increasing demands of business, and it will be more true in the future even than now that the great residential areas of the city will be north of Fifty-ninth Street. It follows, therefore, that the entire traffic below Fifty-ninth Street must necessarily be "short distance," and that a tunnel railway limited to this area will not have a large morning and night travel. It cannot possibly compete with the surface lines, or even the elevated in securing short distance riding, partly because people do not like to go up and down stairs, particularly to a dark, and perhaps a noisy tunnel; partly because the tunnel railway runs to City Hall Park only, and does not serve the lower end of the island, nor has it any large attraction at the northerly end; but chiefly because the most generous system of transfers known probably in any city of the world, prevails on the surface lines, and makes it possible for a would-be traveler to go east and west and north and south between any points by the payment of a single fare. We repeat, therefore, that section I. alone for the proposed terminal railway is a proposition likely to be wholly unattractive to capital.

Will sections I. and II., taken together, be profitable?

That portion of Manhattan Island north of Fifty-ninth Street and west of Central Park and Lenox Avenue has been built up during the past ten years with myriads of private, and apartment houses of the better class. It is generally considered to-day the most desirable portion of the city in which to live, except for upper Fifth Avenue along the Park, given over chiefly to the residences of the extremely wealthy. The density of population in this West Side area is not large, however, for the class of people who inhabit it are those who desire more breathing room than can be had in other parts of the city. The East Side of the city, for example, from 125th Street to the Battery, is of enormously greater value from a railroad point of view than is the West Side, for it is here that the "tenement houses" proper are found, together with a busy, humming industrial life, which forms a great contrast to the quiet, peaceful streets of the West Side district.

Now, this West Side district to be served by section II. of the tunnel railway is less than three-quarters of a mile wide, except at the part above the park, where it is approximately a mile and a half. This narrow area is now served by a three-track elevated railway on Ninth Avenue, running rapid express trains night and morning, and soon to be equipped for a vastly superior and more rapid electric service; two electric lines on Eighth and Amsterdam Avenues, now in operation and giving an exceptionally perfect service; a cable line in Columbus Avenue, soon to be converted to electricity; a horse line on upper Broadway, immediately over the proposed tunnel line, electrical operation of which by the underground conduit system will begin within a few weeks, and a horse line on Amsterdam Avenue to be run by electricity in due time.

An independent tunnel railway will hardly get from this district more than the through, or long distance, travel. In competition with it will be the surface lines giving free transfers to any part of the city below Fifty-ninth Street, and the elevated lines, giving a service almost as rapid as the underground, with 3-cent transfers over the upper

ROUTE OF THE PROPOSED RAPID TRANSIT UNDERGROUND RAILWAY

Broadway surface line, and many others in the city. The tunnel railway will miss the profitable short distance riding entirely, including the major part of the ladies shopping travel, and if the city insists upon express train service throughout the day, as appears probable, it will unquestionably be conducted at a heavy loss.

The only salvation for sections I. and II., as a railroad proposition, is that through their construction upper Broadway from Forty-second Street north will become a great business street similar to lower Broadway. We doubt if this will happen, for many years to come, at least, for the "feeder district" to such a street is narrow and is populated by a class of people who would resent the introduction of the business element into this region. Eventually, perhaps, when some outlet above the Park has to be given for business development, the existence of such a railway as this would determine the march of progress, and the city would be better balanced than would otherwise be the case. We believe, however, that sections I. and II. of the proposed tunnel railway, taken together, would be unprofitable for a number of years to come.

Sections III. and IV. would be of immense benefit to the "Annexed District" and the upper end of Manhattan Island, and in a comparatively short time after the completion of the road this whole area would form another city. It is probable that the tunnel railway could secure practically all of the business from this area to the lower end of Manhattan Island, and that its morning and evening trains, both express and local, would be crowded. But consider a 5-cent fare for such long distance travel! If a business of this kind is profitable for such an enormously costly railway as is the proposed tunnel line, surely the surface and elevated railways of New York must be Golcondas indeed!

Passing now from the consideration of the details of the project, let us summarize the general financial requirements of this railway, assuming it to be independent of all other transportation systems in the city. The tunnel railway will probably cost as a whole not less than $40,000,000, and its equipment not less than $10,000,000. The rental, and a fair interest on cost of equipment would be not less than $1,500,000 per annum for the first five years. On this railway, built avowedly for long distance traffic on a uniform 5-cent fare, it can hardly be expected that operation at less than 70 per cent of the gross receipts can be achieved. If this is so, the railway must earn $5,000,000 per annum during the first five years in order to save the operating company from loss—to say nothing of leaving it any profit. The network of present transportation lines shown in the map on page 881, a network consisting of four trunk elevated railways from the Battery to the Harlem River and beyond; twelve trunk surface lines north and south on Manhattan Island; innumerable crosstown feeders to these elevated and surface trunk lines; and a widely ramified surface railway system above the Harlem—is earning only about $25,000,000 per annum gross. Can a single line through and to territory such as has been described, and without feeders or crosstown connections, earn one-fifth of this grand total? Frankly, it does not seem to us probable, at least until, as said before, the city shall have so fully outgrown its surface and elevated facilities of travel as to be forced to take to the underground for short distance riding.

We have spoken so far of the tunnel railway as a wholly independent proposition. There remains for consideration the question as to whether or not it will be a profitable adjunct to any of the existing surface or elevated systems. Will the Manhattan, Third Avenue or Metropolitan syndicates see an opportunity for strengthening their grip upon the transportation industry of New York, and of making additional profits for themselves?

It is hard to see how ownership of the tunnel railway by the Manhattan Company would strengthen either property, as there is little chance of cross connection or valuable transfer arrangements. What the Manhattan Company needs to-day more than any other privilege is that of building short connections for its four trunk lines on various important streets across the island. The rapid transit tunnel must be essentially a competitor to Manhattan for long distance traffic, and it is not the long distance traffic which the Manhattan Company needs, or is seeking.

Were the tunnel railway owned by the Third Avenue or Metropolitan Companies a transfer system might be introduced which would be of benefit to both tunnel and surface lines. In this case, the surface lines would be distributing and collecting agencies—the tunnel railway would be one only of the through lines. But the questions arise, first, why either of the great surface companies should go to great pains and enormous expense to give to the people a long distance combined surface and underground ride for 5 cents on a free transfer plan, or, second, whether a sufficient amount of traffic could be secured on a 7-cent or 8-cent joint rate to warrant the arrangement of a costly through service of this kind. The function of the surface lines of New York City is, and always will be, to handle the short distance traffic, and their interests lie in the direction of forcing to the elevated or underground lines the less profitable long distance riding, thus freeing their cars for the better class of traffic. Are they prepared to accept the financial responsibilities of "the other end," i. e., assume the burden of catering to the long distance riders of the city on a 5-cent fare?

It is with the greatest reluctance that we have been forced to the conclusion that the Rapid Transit Commission's present plans and proposed contract do not afford sufficient inducement to capital to warrant the confident hope that the tunnel will be built. We sincerely hope that our view of the case may be a mistaken one, and that the risks may be assumed, for certainly New York City needs now, and will in the future even more urgently need, every transportation agency which can be crowded into Manhattan Island. If responsible parties can be found to undertake the task upon the present basis, we shall be heartily glad, and will be first to congratulate the Rapid Transit Board on its success, though we should not advise the "widows and orphans" to invest their money in securities representing such a railway. If capital says "no," we should strongly advocate a more liberal proposition, such as, for example, the right to charge graded fares up to 10 cents for the longer distances, or the right to charge a 10-cent fare for express train service, with a 5-cent fare for local. We all want better transportation facilities in New York City, and, within reasonable limits, the time saving is of more importance than is the saving of the last penny of transportation cost.

Transportation Earnings and Profits on Manhattan Island

The changes brought about during the past fifteen years in the transportation conditions of New York City, and particularly of Manhattan Island, are hardly yet fully understood by the people, or even, perhaps, by many of the capitalists interested. A mere examination of the city railway reports from year to year does not convey an adequate idea of the results of the intense struggle for traffic which has been going on, or of the true influences at work, and a retrospect of at least ten or twelve years is necessary if this understanding is to be gained. There were then found on Manhattan Island no less than twenty operating companies, surface and elevated, each working in its own special, but limited, field, and each at peace with its neighbors save for an occasional quarrel over the replacement of a crossing or some small question of trackage rights. Horses were used on all the surface lines except on a single cable road "away out in the country," on 125th Street in Harlem, and no disturbing thoughts of radical improvements in service or the introduction of new motive powers were troubling either the railway companies or the people.

From the standpoint of our present knowledge we can see that the most important event in the transportation history of Manhattan Island, and perhaps in its recent general history as well, was the purchase in 1886 by a small group of Philadelphia capitalists of a controlling interest in the Chambers Street and Grand Street Ferry Railroad Company, and the Houston, West Street and Pavonia Ferry Railroad Company. There was then introduced into the local situation an element of progressiveness and aggressiveness which was destined in a few years to leaven the whole lump, and to turn a comparatively sleepy Dutch city into a modern American metropolis.

For five or six years this long-headed "Philadelphia Syndicate" laid its plans and carried them out quietly but most effectively. Control of one after the other of the local horse railway properties was purchased at prices then deemed extraordinary—even extravagant. The former owners congratulated themselves heartily, and with reason, upon the excellent bargains which they made in disposing of their stock holdings. Purchases were not infrequently made on a 4 per cent or even a 3 per cent basis. These bargains were, in truth, of a kind advantageous to both purchaser and sellers, inasmuch as the latter could never do with their isolated properties what could be accomplished were they welded into one great system, while the purchasers, with a largeness of conception and a wealth of financial resource never before found in street railroading in this or any other country, were able to consolidate into a single great property no less than three-fourths of the entire surface railway mileage of Manhattan Island.

It is not to be supposed that these purchases and consolidations were effected without the opposition of powerful rivals in the field. It was not, however, until the principal work of purchase had been done that this opposition crystallized into any definite form. The Third Avenue Railroad Company, though more than once approached by the Philadelphia syndicate, with a view to purchase, resisted all blandishments, and eventually, though very "late in the game," purchased on its own account control of the two horse railway properties on Manhattan Island, left in independent operation by the Philadelphia syndicate, the Forty-second Street, Manhattanville & St. Nicholas Avenue Railway Company and the Dry Dock, East Broadway & Battery Railroad Company, while, a little later, control of the Union Railway Company, with its connections, operating under most valuable franchises through the entire "Annexed District," above the Harlem River, was also secured by the Third Avenue Company. Prior to these purchases the Metropolitan Street Railway Company, into which had been consolidated or to which had been leased all the properties purchased by the Whitney-Widener-Elkins syndicate, had built a new cable line on Lexington Avenue, paralleling the Third Avenue main line on the west, and had secured control of the Second Avenue Railway paralleling it on the east, and soon afterward a lease to the Metropolitan Company of the Fourth Avenue line of the New York & Harlem Railroad Company was effected. At the same time general transfers were introduced all over the Metropolitan Company's system, from cross town to north and south lines, and the Third Avenue Company finding itself surrounded by sharply competing lines and in an uncomfortably isolated position, made the purchases referred to in order to obtain outlets and feeders for its main line.

The Manhattan Railway Company, operating all the elevated lines in the city, seems never, until recently, to have taken any interest in the surface railways of New York, and it did not see until too late the tremendous influence which was to be exerted upon its own gross and net earnings by the intelligent competition below its tracks. This competition began to be felt by both elevated and Third Avenue systems even while the Metropolitan syndicate was still operating its purchased lines by horses, and before the great work of improving the motive power was commenced, for what had been at first a mere agglomeration of individualized horse railway lines, each run by its own superintendent, upon different policies of management, were unified in such a way that economies could be effected and the service greatly improved. New routes were laid out for the better handling of traffic, and transfers were introduced, while it will be remembered that the Broadway horse cars were the best equipped and the fastest in the city, in spite of the great congestion of that thoroughfare.

In 1890 the Metropolitan syndicate determined to cable its Broadway line from the Battery to Fifty-ninth Street. At about the same time the Third Avenue Railroad Company obtained the long-sought right to cable its main line on Third Avenue. It was then generally believed by engineers and street railway managers that for a traffic of such enormous density as that of Broadway and Third Avenue—a density greater perhaps than that of any other lines in this country—the cable system was far superior to any form of the electric, and would never be superseded. Following the equipment of the Broadway line, the Lexington Avenue and Columbus Avenue cable lines were built as branches to the main Broadway stem. Thus was the work commenced of improving the motive powers on New York City railways, the Third Avenue Company really taking the lead in the building of its 125th Street cable line in 1886, and the Metropolitan syndicate taking the lead in main line work.

The attempt was next made by the latter to secure the right to introduce the overhead wire electric system on Sixth Avenue under the elevated structure, but the people of New York had just gotten rid of overhead electric wires, literally by main force, and were determined to have no more, so that this attempt completely failed. The situation confronting the syndicate was now most puzzling, and disaster stared it in the face. All plans had been based upon the securing of these overhead electric rights, as had been done with comparative ease in Philadelphia and other large cities of the country. The purchases of horse properties had been made at high prices with this in view, and if they were forced to continue operation by horses or to go

to the enormous additional capital expenditure required for the cable system, success was by no means assured.

In this emergency it was determined, with characteristic courage, to undertake an elaborate experiment with the underground conduit electric system, which had until that time a record of uniform failure wherever tried in this country, though it was claimed to be partly successful in a single European city. The Lenox Avenue line was built with a conduit of such size that if electricity should prove a failure, the cable could be installed. The success of this initial experiment was so pronounced that the decision was made in 1897 to adopt the underground conduit electric system in somewhat modified and cheaper forms for all the north and south lines owned by the Metropolitan Company, the decision regarding motive power for the cross-town lines being left till a later date. As a consequence, there have been put into operation during the past two years the Second Avenue, the Madison Avenue, the Sixth Avenue, the Eighth Avenue and the Amsterdam Avenue lines, all by the underground conduit electric system. The instant success of the new electric cars in winning popular favor and the great increase in traffic over the old horse lines which they replaced, has been so marked that it has been determined to convert all the present cable lines of both the Metropolitan and Third Avenue Companies to underground conduit electric, and in accomplishing this the Third Avenue has led, its complete line from City Hall to Harlem having just been put into operation, while work upon the Broadway system is going on as rapidly as circumstances will permit, and it is expected that the change will be completed next year.

For reasons which will presently appear, the Manhattan Railway Company has determined to make a change of motive power from steam to electricity, and ground has been broken for its new power station, for which a portion of the equipment has been ordered, while contracts for its car and other equipment will shortly be placed.

Having thus briefly reviewed the street railway history of Manhattan Island during the past twelve years, and further referring to the map on page 880, showing the lines of the three competing systems, we are now prepared to examine the diagram, Fig. 1, which shows how all these changing conditions have influenced the relative traffic secured by these systems. In 1888 the Manhattan Company and its later acquisition, the Suburban Rapid Transit Company, the latter operating in the "Annexed District," showed passenger earnings of $8,695,347 gross. The company's earnings steadily increased until 1893, when they became a maximum at $11,070,360. From this point on the record is dark, the falling off in earnings being precipitous for two years, and then more gradual until in the year just ended (June 30), the company is back to almost the starting point in 1888, with but $8,703,996 passenger earnings.

The Third Avenue system on Manhattan Island (by which we mean here and elsewhere in this paper a combination of the Third Avenue Railroad, the Forty-second Street, Manhattanville & St. Nicholas Avenue Railway, and the Dry Dock, East Broadway & Battery Railroad, excluding, therefore the Union Railway and its allies in the "Annexed District") earned in 1888 from all sources $2,693,874, and for the next two years these earnings were slightly increased. Then followed a four-year period of but little change, after which the traffic winning influence of its new main line cable system became evident, a maximum of earnings being reached in 1896, when $4,097,268 was obtained. For two years following this the Metropolitan competition is seen in slightly declining earnings, and in the year just ended this decline is decided, owing no doubt in part to the interruption to traffic caused by conversion from cable to electricity, but in part also to the competition of the Madison Avenue and Second Avenue electric lines, which have been most popular means of surface transportation on the East Side.

What have the Metropolitan syndicate lines been doing meanwhile? In 1888, the fourteen companies then in existence which were later merged into the Metropolitan system, were earning $7,268,901. Now, the Metropolitan system, including the mileage of these fourteen original companies and that of several others built from time to time since 1888, is earning nearly double the income of that year, or $14,133,810.* The course of the line of growth in the earnings of the Metropolitan system may be traced in the diagram, and is sufficiently indicative of the reward given by a great city to enterprise and generosity, in the management of a transportation system.

In examining the course of gross traffic, however, we

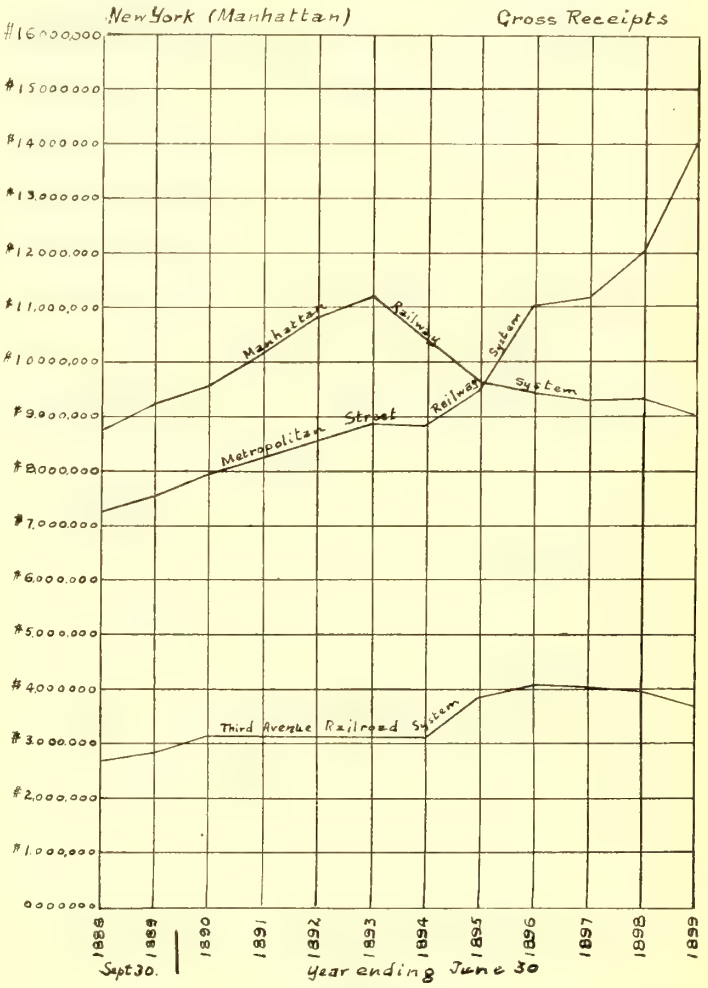


FIG. 1

are taking a merely superficial view of the whole question. The investment and operating costs necessary for obtaining new traffic or for keeping that which is retained are of deeper interest and in some aspects really reach the heart of the transportation problem of this great city, having a bearing upon the possibilities of the new rapid transit railway perhaps to be constructed, and indicating the probable future of the existing systems in competition. We may pass then to the consideration of the financial history of the three great systems, as expressed in the diagrams, Figs. 2 to 7, in which are exhibited in graphical form the relations of capital stock, funded and floating debt, and the disposition of gross earnings.

* This figure includes the operating and other income of the Metropolitan Street Railway Company proper, the Central Crosstown Railroad Company, the Thirty-fourth Street Crosstown Railroad Company, the Twenty-eighth & Twenty-ninth Streets Crosstown Railroad Company, and the Fulton Street Railroad Company.

The Third Avenue Railroad System

The Third Avenue Railroad system on Manhattan Island consists (a) of the main stem on Third Avenue, now a double track electric railway; (b) of a crosstown line on Forty-second Street from North River to East River, now running by horses, but in process of change to electricity; (c) connecting with this, a line through upper Broadway to Fort Lee Ferry, also running by horses now but to commence electric operation within a few weeks; (d) a crosstown line on 125th Street from river to river, now in operation by electricity; (e) a line from 125th Street to Fort

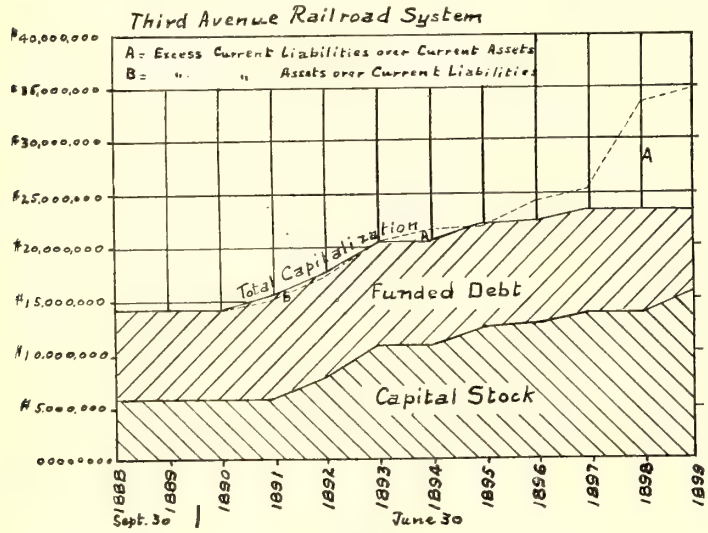

FIG. 2

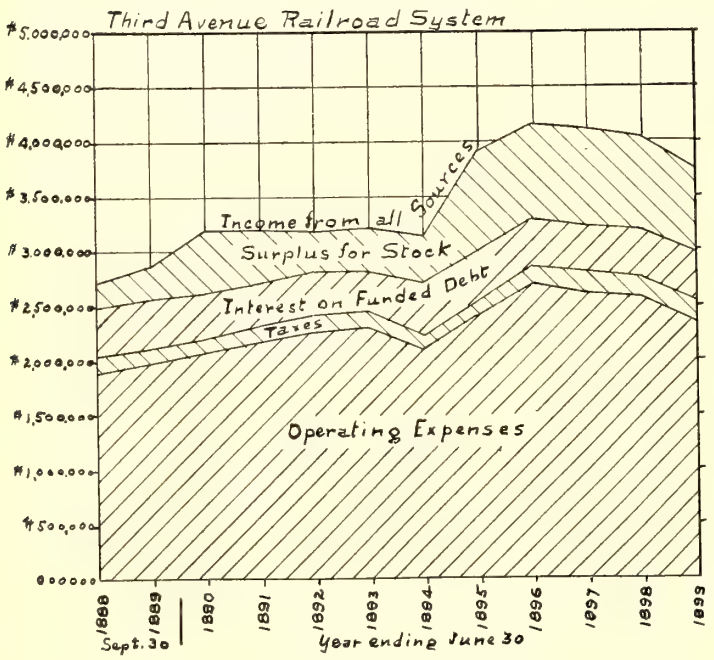

FIG. 3

George, at the upper end of the island, now running in part by electricity and in part by horses; (f) a crosstown horse railway line from the East River through 110th Street and St. Nicholas Avenue to Fort Lee Ferry; (g) a crosstown horse railway system in the lower part of the island, and (h) a line on Amsterdam Avenue to be run by electricity. The following figures and the diagrams do not include the Union Railway and its connections in the "Annexed District," control of which is owned by the Third Avenue Railway. This latter system is nearly self-supporting on an interest paying basis, but is not now adding to the dividend earning capacity of the Third Avenue system, though there is no question that in course of time the Union Railway Company's lines will be of great value, from the large growth of population expected in this comparatively new section of the city.

Referring to Fig. 3 the proportion of the total income paid out by the Third Avenue system in operating expenses, taxes and interest on funded debt for each year since 1888 are clearly seen, and surplus earnings for stock are shown to be at a maximum in 1895. In the three following years they fell off slightly, and in 1899 the reduction is considerable, owing in part, no doubt, to the difficulties incident to the period of reconstruction. The capitalization, both in stock and funded debt, has increased but gradually, but a large floating debt has lately been created, as is seen by the diagram, Fig. 2, so that the total stock and debt at the present time amounts to about $35,000,000. This floating debt doubtless represents in large part the cost of stocks of controlled companies purchased, together with the not yet capitalized cost of electrical construction, and the stock and debt outstanding should be reduced by the par value of the controlled stocks in the Third Avenue treasury, whatever this value may be. For various reasons not connected with the present discussion, the company has chosen to finance its electrical reconstruction by the proceeds of stock sales instead of bonds, and the entire capitalization (in stock and funded debt) of the whole Third Avenue system will probably be eventually about $50,000,000.

If, now, a return of 5 per cent is to be made on both stock and bonds of the Third Avenue consolidated system, a gross earning power of between $5,000,000 and $6,000,000 must be reached in order to obtain the necessary $2,500,000 for stock and bonds. The present earning power of the whole system, including not only the lines on Manhattan Island, but those in the "Annexed District" and Yonkers, is approximately $4,500,000.

The Manhattan Railway System

In the diagram, Fig. 5, is seen the disposition of the income from all sources of the Manhattan Railway system, including the "Suburban" extension in the "Annexed District," whose earnings cannot now be separated from those of the system on Manhattan Island. It will be seen that the surplus left for stock was large in the earlier years of the enterprise, and reached a maximum in 1893, since which time it has fallen to comparatively small proportions, and is now (year ending June 30, 1899) smaller than ever before in the twelve-year period, except in 1896, when it was but $2,000 less.

There is another most significant feature of the Manhattan diagram. It is here brought out in the clearest and most unmistakable way how the fact that the Manhattan Company has lost its short distance riders to the surface lines, and has retained only the long-distance traffic, affects profits. It is seen that in spite of the great reduction in gross income, the operating expenses have been reduced but slightly, while the expenses and taxes combined have been on an almost constantly increasing scale. Ordinarily in railroading expenses are increased and reduced in some proportion to gross income, but the Manhattan Company has been apparently unable to do this. The well known fact that a seat can now be generally obtained in the elevated cars except in the rush hours, is collateral evidence that the Manhattan Company is keeping up its train service with diminishing traffic, and it is probable that were this not done the falling off in traffic would be even more serious than now.

It goes without saying that the short distance riding on any railroad where uniform fares are charged is the profitable traffic, the long distance the less profitable or unprofitable. If the proportion of the short distance riding is large,

the percentage of operating expenses to gross receipts will be small. If the long distance riding predominates the percentage is larger. The Manhattan Company's experience is instructive, and the following table, showing the percentage of operating expenses to receipts from operation during the past twelve years, is even clearer evidence as to how great is the loss of short distance riders.

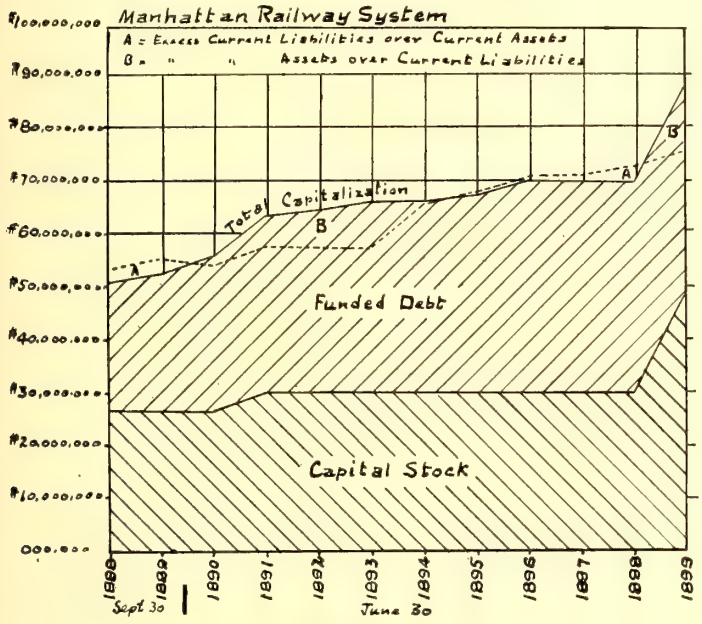

FIG. 4

Percentages of operating expenses to operating income of the Manhattan Railway system, 1888-1899.

	Per cent		Per cent
1888	55.1	1894	54.5
1889	54.5	1895	57.6
1890	52.7	1896	59.7
1891	50.9	1897	57.9
1892	50.7	1898	58.0
1893	50.3	1899	60.3

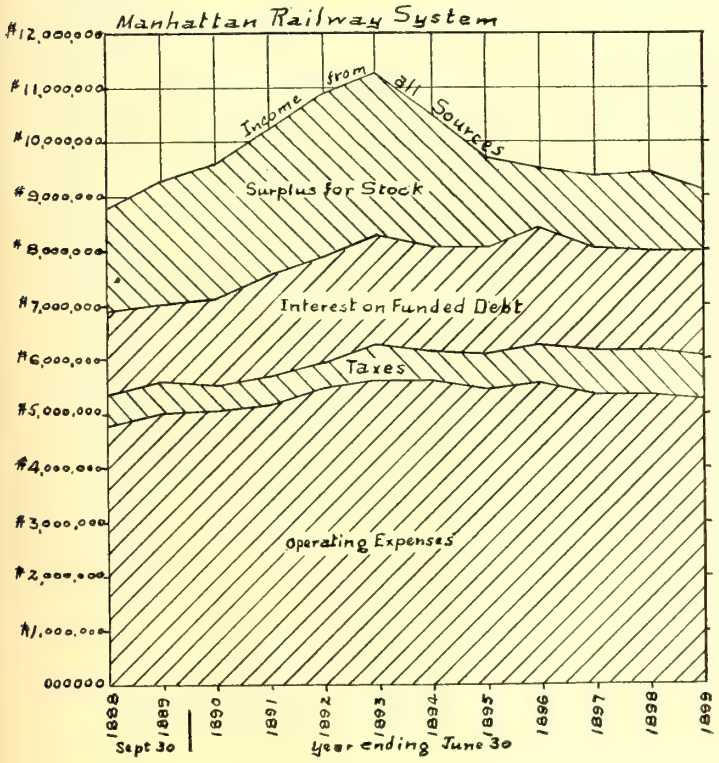

FIG. 5

What does the future hold in store for the Manhattan Company? Can it regain its lost earnings, gross and net? What will be the effect of electrical equipment upon its dividends? These are the questions which are puzzling the managers of this great enterprise.

This may be said broadly, that in the course of time, perhaps ten years hence, perhaps even less, every transportation agency on Manhattan Island will be taxed to its ut-

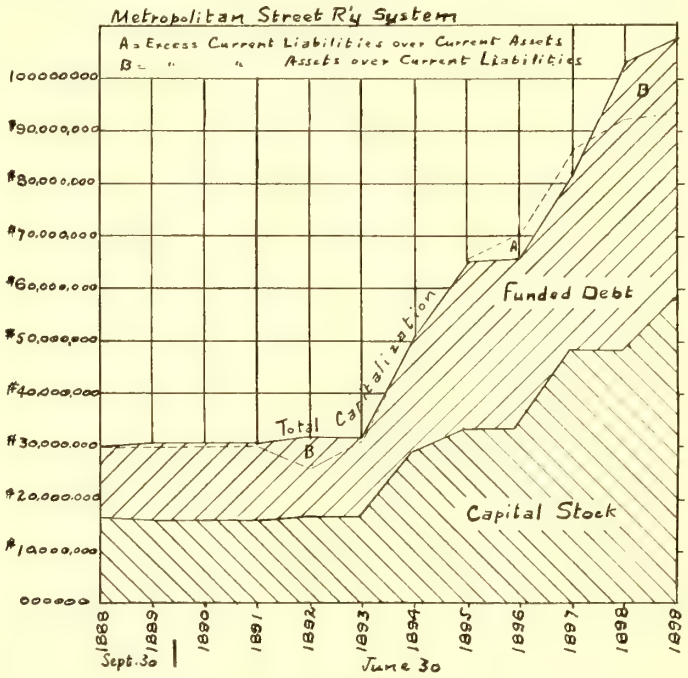

FIG. 6

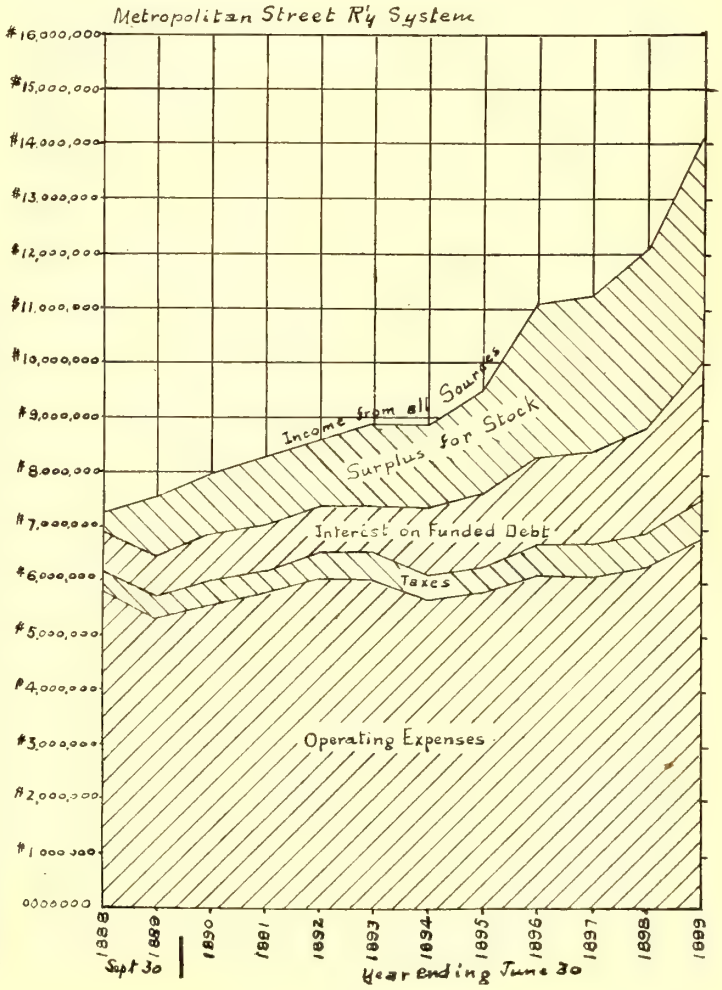

FIG. 7

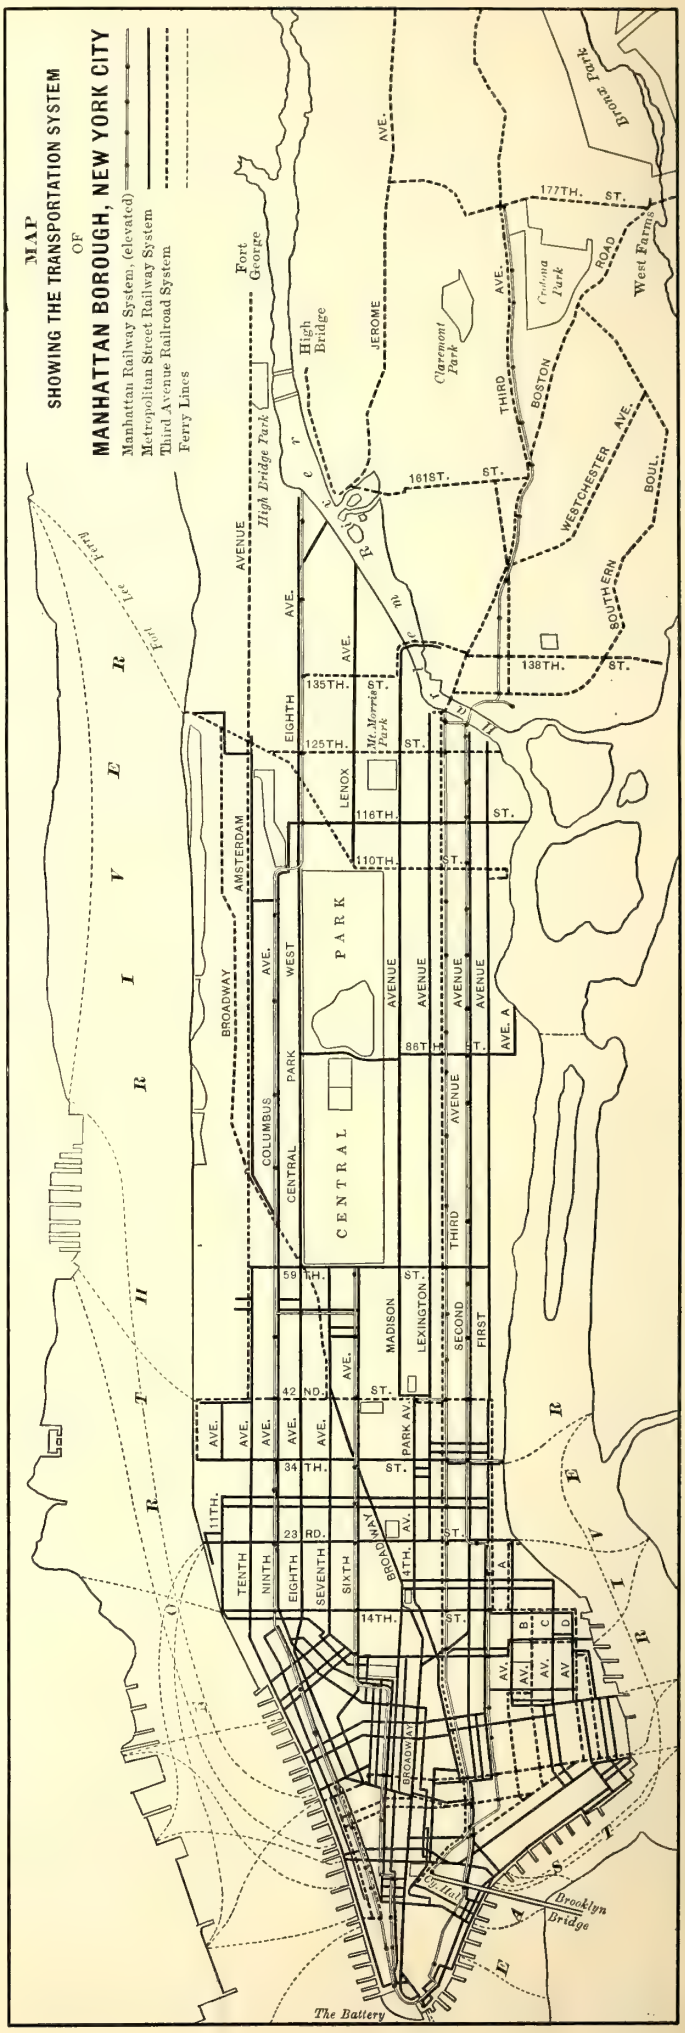
most to provide accommodation for a traveling public greater by far in numbers and in freedom of patronage than exists to-day. Even should the Manhattan Company

fail to make any great improvements upon its system, its cars would probably, in time, get back much of their lost business, from the simple inability of the people to crowd upon the surface cars. The next few years of such a policy would, however, be disastrous to the company, and, in fact, for the next three or four years at least, if not for more, during the period of electrical equipment, the Manhattan Company must look forward, with what grace it may, to the prospect of diminishing gross and net earnings, since in addition to the still increasing facilities offered by the surface lines, there will be the interruptions to traffic coming with the physical work of electrical equipment.



What electricity should do for the Manhattan system is to advance by a few years the period of returning traffic. How many years this will be advanced depends upon the wisdom of the decisions made by the present management. If they go into electrical equipment with the idea of saving money in operating expenses rather than of working up an increased traffic, they will miss their real opportunity, and will suffer in consequence. The cheapest thing which any electric railroad or street railway can buy or make is *power*—the most expensive thing is *labor*. If the Manhattan Company is "penny wise and pound foolish" it will buy motors and equip its power station with the idea of running its cars at the present schedule speeds, or but very little faster. If it deals with the subject in a broad and comprehensive way, determining to give the people what the people need—genuine rapid transit—it will buy large motors and large generators, and spend power freely in sending its trains over the road at much higher speeds than could ever be obtained by steam; it will put electric elevators at all its stations throughout the city; it will adopt types of cars attractive to the public, both in summer and winter; and, in short, it will be generous to the people, of New York City, who are, perhaps, of all city peoples, most quick to appreciate and use the best things of all kinds offered to it.

The immediate future of the Manhattan Company is measurably in its own hands. It is only a pity that in an age of progress and rapidly changing conditions it should have delayed so long in taking advantage of its immense potentialities. It might have controlled the transportation industry of New York City—it has let the opportunity slip from its grasp, and it can never be regained.

The Metropolitan Street Railway System

The remarkable growth in gross earnings from $7,071,940 in 1888 to $13,423,020 in 1899 has already been referred to. A more remarkable thing is that with this 90 per cent increase in gross, the operating expenses show an increase of but 17 per cent, namely, from $5,797,912 in 1888 to $6,783,913 in 1899. This is an exact reversal of the Manhattan history. For return on capital investment there was left in 1888 but $853,970, of which only $118,510 was appliable to dividends on stock, equivalent to less than three-quarters of one per cent upon the $16,221,800 of combined capital stocks of the fourteen, then existing, Metropolitan properties. For the year just ended, the net earnings for interest and dividends amounted to $6,639,816, nearly eight times as much as in 1888, and the surplus left for stock was equivalent to $4,154,506*, or 7 per cent on $58,498,500. Truly a remarkable showing is this, and one which reflects the greatest credit upon the ability of a management which, it is probably safe to say, has few equals and no superiors among the street railway properties of the United States.

What is the future of the Metropolitan system? The

* This figure includes the operating surplus for stock of the Metropolitan Street Railway Company, the Central Crosstown Railroad Company, the Thirty-fourth Street Crosstown Railroad Company, the Twenty-eighth & Twenty-ninth Streets Crosstown Railroad Company (def.), and the Fulton Street Railroad Company (def.), together with the guaranteed dividends on all other properties controlled by the Metropolitan Street Railway Company and the Central Crosstown Railroad Company, through lease.

answer is simple. With continued good management it can hardly fail to become one of the great investment properties of New York City. At present, on a 7 per cent dividend paying basis, it has still over 100 miles of track, representing nearly half its entire mileage, operating by horses —the most antiquated motive power of all. When the complicated network of crosstown lines in the lower end of the city is equipped with some of the cheaper forms of improved motive power, such as compressed air or storage battery, with which enormous investment for conduit construction is not required, the amount of short distance business riding will be vastly increased; when the new power station at Ninety-sixth Street, now nearly finished (from two to three years ahead of the Manhattan and Third Avenue power stations, work on whose foundations has but recently commenced), begins to furnish power for the entire system; and when the new cars constantly building for the Metropolitan Company to supply its urgent demands have arrived in sufficient quantities to take care of the traffic offered; service on the north and south and crosstown lines can be brought to a point more nearly meeting the requirements and largely increased gross and net earnings will inevitably result.

The Proposed Rapid Transit Tunnel Railway

A tunnel railway is projected by the Board of Rapid Transit Commissioners of New York City, and bids for its construction and operation have just been invited. The question as to how such a railway as this would, if built, influence the earning power of the present companies is an interesting one. The answer probably is that irrespective of what the effect might or might not be were the new road at present in operation, the city will, during the five-year period allowed by the Commission for construction, quite certainly grow to the additional facilities which it will offer, and the deliverance from the daily woes of travel which it will offer will be but temporary. The underlying fact which impresses itself upon all who study New York transportation conditions is that in this long, narrow island, upon which a mass of travel surges down in the morning and up at night—this metropolis of America, which is daily attracting more and more permanent residents and temporary visitors—the demand for transportation facilities will always and inevitably be far ahead of the possible supply and every means of relieving the congestion should be welcomed. The proposed rapid transit tunnel will serve to populate, and immensely increase the value of, the upper portion of Manhattan Island and the Annexed District, and it will carry express traffic, not local. Eventually the 6-mile to 10-mile travelers will use the tunnel railway, and 3-mile to 6-mile travelers the elevated system, and the half-mile to 3-mile travelers the surface lines. The surface lines will make much money, the elevated some, and the tunnel railway, it is very much to be feared, will make, for some time at least, but little, if a 5-cent fare is insisted upon.

Electric Railways in Japan

BY W. DELANO EASTLAKE

The street railroad question has reached Japan, and is at present disturbing the Oriental equanimity of the Japanese authorities more than anything else has done for many years past. The government has long since been alive to the fact that an adequate system of urban transportation is a necessity in many Japanese cities. The old style "kago" or sedan chair, long ago was superseded by the more rapid "Kuruma," or jin-riki-sha, those quaint little carts which are pulled by coolies at a breakneck speed. But even the kuruma has proved its inadequacy, and the authorities have started out to find a satisfactory substitute.

Some years ago a trolley line was equipped in Kyoto, and still remains as a monumental evidence of Japanese confidence in American integrity, and the marvelous intrepidity of whatever firm sent out the plant. To say that it is the worst sort of a failure would be to put it very mildly indeed. To be sure it is still in operation, but its uses are now similar to those of a merry-go-round at an American pleasure resort. People from the country, when visiting Kyoto, ride on the electric monster with a dare-devil spirit that is truly enviable. It is a single track system, with a switch at every few blocks, in which the uptown car must wait until passed by the downtown car. These waits are never less than ten or fifteen minutes, and I have frequently known them to last half an hour or more. To be sure, walking is a much quicker way of getting to one's destination, but then think of the excitement of the thing!

It were almost needless to say that the line does not pay were it not for the fact that it declared a 10 per cent dividend last year, and there is another short trolley line in Nagoya, equally as curiously equipped, which is paying 7 per cent dividends. Tokyo, the capital of the empire, a city of over a million and a quarter inhabitants, rejoices in a horse car line, some 8 miles in length, double track, with a capital of one million yen, or $500,000, which is now paying annual dividends of 35 per cent. Even this line, which is the best in the country, would shame the most backward village in the States, but it is enormously profitable for all that. Besides this stupendous dividend, the Tokyo Tramway Company, as it is called, also declared a reserve dividend of 10 per cent last year, which was added to the capital. The present Tokyo systems include, besides the above mentioned tramway company, the Shinagawa Tramway Company and the Senju Tramway Company. The prospective lines include a complete system in Osaka, the next largest city to Tokyo, which is already in the course of construction, or, at least, was to have been started this month; a line between Tokyo and Yokohama, which will be 18 miles long; a line between Kobe and Osaka, and lastly and most important, a complete system for Tokyo, including a belt line. There is one other existing electric road in Japan, which runs—no, moves—between Kodzu and Imoto-Hakone, called the Odawara Electric Company, and which is paying 7 per cent dividends.

Again, there is talk of converting the present Tokyo Tramway into an electric line at an early date. The specifications, among other things, call for rails weighing 50 lbs. per ft., wheels 30 ins. in diameter, and a distance of 7 ft. between the front and rear wheels, or not less than 6 ft. 6 ins. The length of each car is to be 24 ft., their weight, with fifty-two passengers, not to exceed 10 tons; the cars to run at three and five minutes headway, and to make from eight to thirteen round trips daily. Total length of track, 16 miles.

But all this is still on paper, for the authorities have not yet decided upon the system which, if adopted, will become universal in Japan. Not long ago an official (Mr. Fujita) came to this country for the special purpose of looking into the various systems now in vogue, both in this country and in Europe, and while his report was most careful and valuable, it did not bring the authorities to any conclusion. The opinion seems very strong in Japan that the overhead trolley system will soon be superseded by a more modern and perfect one, and so long as they have waited thus long they consider it wise to wait until whatever system is adopted has at least passed beyond the experimental point in foreign lands. There is, however, no doubt but what some system is soon to be adopted, and it largely depends upon the zeal of our manufacturers as to whether that system shall be an American one or not.

LEGAL NOTES AND COMMENTS*

Edited by J. Aspinwall Hodge, Jr., of the New York Bar

A Book on Patent Law for Laymen as Well as Lawyers†

It is seldom that a law book is useful in the hands of the layman; but Mr. Greeley's work on foreign patents and trade mark laws is an exception to this rule, especially in the latter half of the volume which treats of trade mark laws.

We venture to assert that the legal status of trade marks, even in our own country, and especially the legal effect of the registration thereof, is not understood by nine-tenths of the owners of trade marks in the country, and if we are mistaken in this statement, we still believe that it is true, concerning the nature of foreign trade marks.

Mr. Greeley's work, therefore, written in terse English, concisely and to the point, bringing down the laws which, of course, are subject to frequent changes, to date, is almost invaluable. It would be so were the laws which he digests, easily obtainable in the English language by those who are in the vicinity of Washington and New York.

A compendium of such laws, published in foreign languages, and some of them to be found only in the annual volumes of foreign laws, adds much not only to the usefulness, but to the virtual necessity of the volume to anyone who would treat with foreign countries understandingly.

There are other works upon foreign patent laws, and standard ones, but they are ten years old or more, and so, in many cases are not reliable when consulted for the existing law. They do not give, as does the volume under discussion, a satisfactory compendium of the trade-mark laws. We quite agree with the author's comment in his preface, that to the business man the trade mark and a knowledge of the trade-mark law is more likely to be useful, and when it is useful, is more advantageously so than a like knowledge of the patent law.

A perusal of the work has suggested that some of our readers may be interested in a few of the essential characteristics of trade-mark laws.

The original trade-mark rights recognized by the courts were recognized not so much to protect the user of the trade mark, as the public, and it is interesting to read the original decisions which look at the matter from that standpoint. It was thought that the public was injured when an article was passed off upon them which was not what they supposed they were obtaining. Afterward, trade marks were recognized as property which should be protected, because people would suppose that A. B. using a certain trade mark was producing inferior goods, since they had bought goods with that trade mark which were not up to the standard; so that A. B. upon showing these facts was able to succeed in the legal contention that arose out of the fact that the inferior goods were being manufactured by some rival.

The registration acts of the various nations, requiring or allowing the user of a trade mark to register the same, vary much; but they can be easily divided into two classes, and there is not much difficulty in classifying the laws of any nation under one or the other of the two classes.

They are either declarative or attributive. Where they are declarative, the property in the trade mark exists quite apart from registration, and the registration of the trade mark is merely declarative of the existence of the property right, and is merely *prima facie* evidence that he who thus registers is the owner and first user;—evidence which can be rebutted by evidence that some one else has used the trade mark prior to the use of it by the person who thus registers it.

Where the attributive law prevails, as it does in many countries, he who first registers, and sometimes irrespective of whether he has used the trade mark or not, has the right to protect himself against all those who attempt to use it, even if prior to his registration thereof they have used it.

A mere statement of these facts shows how important it is that exporters to foreign countries, before the introduction of their goods bearing a trade mark, should protect themselves, especially where an attributive trade mark law prevails.

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

† Foreign Patent and Trade-Mark Laws; a comparative study, with tabulated statements of essential features of such laws. By Arthur P. Greeley, Assistant Commissioner of Patents. John Byrne & Company, Washington, D. C.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

CALIFORNIA.—Bonds—Issuance—Stockholders' Liability.

Under Civ. Code, Secs. 456, 510, which provide that street railroad companies may issue bonds in payment of contracts for constructing and completing their roads, and section 359, which provides that the bonded indebtedness of a corporation may be created or increased by a vote of the stockholders representing at least two-thirds of the entire capital stock, a stockholder is not liable, in an action to enforce his stockholders' liability, for bonds issued in part payment for the construction of the road, for the issuance of which the stockholders never voted.—(Boyd et al., vs. Heron et al., 58 Pac. Rep., 64.)

LOUISIANA.—Appeal—Jurisdiction—Assessment for Public Improvements—Forced Contributions—Paving Streets—Apportionment of Cost—Space Between Tracks.

On motion to dismiss. 1. The matter at issue, being a question of local assessment or charge upon the property of abutting proprietors in a municipality, levied upon compulsion of law alone, to pay the cost of street improvement, and without their knowledge or consent, is a tax, in the sense of the constitutional provision conferring appellate jurisdiction on this court.

2. There can be no difference or distinction in principle between a forced contribution for levee purposes and a forced contribution for street improvement.

3. While it has ever been held with practical unanimity in numerous decisions of this court that the portion of the cost of the paving and improvement of streets and banquettes in cities and towns, which is, under the law, chargeable to abutting property-owners, is not a tax, in the sense of the jurisdictional article of the constitution, yet the reason for so holding evidently is that, under the provisions of the different city charters, such assessments were based primarily upon petitions signed by the abutting property-owners, and consequently not predicated upon the fiat of the Legislature, notwithstanding same are levied upon the theory of local benefits conferred upon the property of said abutting proprietors.

4. The feature which distinguishes local assessments for public State purposes from those for city street improvement is, in all laws except the one under consideration, the assent of the property-owner.

5. This court affirms the proposition announced in State vs. Judges of Court of Appeals, 16 South. 219, 46 La. Ann. 1292, to the effect that "the use of the words 'all cases,' and of the words 'any tax, impost or toll whatever,' clearly indicates on the part of the framers of the constitution an emphasized intention to give to the terms 'tax,' 'toll,' and 'impost' the widest meaning to which they are susceptible, and to allow every citizen to have submitted to the test of legality and constitutionality, by the highest court of the State, any charge upon his property imposed by the State or its subordinate political agencies, when claimed to be legally and constitutionally imposed by them in aid of governmental purposes, whether extending over the whole State, or over particular localities;" and, further, that "it is manifest that the word 'tax,' in this part of the constitution, is used in its largest sense. After the words describing the jurisdiction of this court as extending to all cases involving the legality or constitutionality of any tax, toll, or impost, there is added the word 'whatever;' i. e., whatever the character of that tax, toll, or impost."

6. The present controversy comes clearly within the reason and spirit of that decision, because the cost of the local assessment therein involved is a tax, within the intendment of the jurisdictional article of the constitution.

On the Merits. 1. This suit involves an interpretation of an ordinance of the city of Shreveport which requires that abutting property-holders throughout the length of a street that has been paved shall pay two-thirds of the cost of same, each one paying in proportion to frontage; that the street railroads shall pay in proportion to the space occupied by their roadbed, compared to the width of the street; and that the city shall pay the remainder, this assessment having been made in pursuance of Act No. 10 of 1896, and wholly without the assent of the abutting property-holders. The ordinance is founded upon the supposed authority that is conferred by the second section of said act, which provides that abutting owners shall pay two-thirds of the entire cost, and the corporation shall pay one-third from its general resources, and provided that, where a railway bed or track occupies a part of the street, it shall pay in proportion to the space occupied by its roadbed, compared with the width of the street. Finding, upon comparison of the city ordinance with the statute, that the former has transposed the terms of the latter by stating (1) the share of the abutter to be two-thirds, (2) that of railroad companies in proportion to the space occupied by them, (3) the city should pay the remainder, whereas the latter states (1) the share of the abutter shall be two-thirds, (2) the city one-third, and, (3) provided

that a street railway occupies a portion of the street, it shall pay in proportion to said space, same are irreconcilable.

2. Entertaining the view that the ordinance is not in keeping with the terms of the statute, the true import of which is to require the portion of the cost due for street improvement by railroad companies to be first deducted from the total amount, and the remainder distributed between the abutters and the municipality, two-thirds to the former and one-third to the latter, same is declared null and void.

3. The uniform current of judicial opinion affirms the principle that the right of occupancy of a portion of the streets of a municipality by a street railway corporation is property which is benefited by a street improvement, to the extent of the space occupied by its roadbed and tracks, which renders same liable for its proportionate share of its cost, just as the property of abutting property-owners is liable; that the railway company using the streets for the operation of its cars is in duty bound to pay for the work on the streets which its track alone makes necessary—that is to say, all expense for that portion of the work lying between the exterior rails of the track of the road, and for a distance of 2 ft. from the exterior to the track on each side thereof.

4. That in no case can any portion of the cost of such improvement be attributed to, or assessed against, the abutting property-owners.

5. That, when a statute or municipal ordinance makes provision for the assessment of a street railway corporation for the pavement of such space as its tracks and roadbed occupy, such provision is mandatory, and any portion thereof which is put upon the abutting property-owners is illegal and void.

6. The very object and aim of such a statute as the act in question is to relieve the municipality and abutting owners, proportionately, from defraying any portion of the cost incident to the part of the street improvement covered by the tracks of a street railway.

7. The space occupied by a street railroad company is matter of proof, to be administered and determined in some proceeding contradictorily between all parties in interest—the municipality, the abutting property-owners, and the street railway companies; and the ordinance which arbitrarily fixes said space, without a contradictory hearing, cannot be sustained as valid.—(City of Shreveport vs. Prescott et al., 26 So. Rep., 664.)

UNITED STATES COURTS

NEW YORK.—Appealable Decrees—Violation of Injunction.

An order imposing a fine for violation of a preliminary injunction cannot be reviewed except upon an appeal from the final decree in the cause.—(Nassau Electric R. Co. vs Sprague Electric Railway & Motor Co., 95 Fed. Rep., 415.)

PATENT DECISIONS.—Suit for Infringement—Preliminary Injunction.

Where the question of infringement is a doubtful one, and to sustain the claim requires a broader construction of the claims of the patent than has been given in prior adjudications, such question should not be determined on a motion for preliminary injunction.—(Sprague Electric Railway & Motor Co. vs. Nassau Electric R. Co., 95 Fed. Rep., 821.)

Anticipation—Buffer Spring for Trolley Arm.

1. A patent for a buffer spring so constructed as to come into operation when the upwardly pressed trolley arm of an electric railway car has assumed a vertical position, and, by engaging therewith, prevent damage being done to the trolley, or by it to the car on which it is placed, was anticipated by the prior use of similar springs as recoil buffers to receive the shock of the projector arm in devices for throwing glass balls as targets.

Same.

2. The Baker patent, No. 437,961, for an improvement in trolley devices for electric railways, was anticipated by the Holden patent, No. 244,897, and the Bloom patent, No. 313,804, covering analogous devices in traps for throwing glass balls, and also by the Van Depoele patent, No. 405,750, for an improvement in trolley devices.—(Thomson-Houston Electric Co. vs. Rahway Electric Light & Power Co., 95 Fed. Rep., 660.)

LIABILITY FOR NEGLIGENCE

CONNECTICUT.—Action for Injuries Causing Death—Evidence—Photographs—Argument and Conduct of Counsel—Reading Reports.

1. In an action against a street railroad company, where it was charged with negligence in allowing the rails of its track to project above the roadway, testimony as to the condition of the street at places other than place of accident was inadmissible.

2. In an action against a street railroad company for negligence in maintaining its roadway, testimony showing the condition of the track at and near the place of the accident within a year prior thereto is admissible.

3. In an action against a street railroad company for negligence in allowing the rails of its track to project above the roadway, a photograph of the street, including the place of the accident, is not admissible to show the height of the rails and the condition of the roadway, without any evidence as to its accuracy.

4. Where counsel, in his closing argument to the jury, attempts to influence them by reading findings of fact in a similar reported case, the court may properly dismiss the panel.—(Cunningham vs. Fair Haven & W. R. Co., 43 Atl. Rep., 1047.)

MINNESOTA.—Injury to Passenger—Excessive Damages—Evidence.

1. Evidence considered, and held sufficient to justify the jury in finding that defendant's servants were negligent.

2. Damages held not to be excessive.

3. Certain questions of practice and admissions of evidence considered and disposed of.—(Fonda vs. St. Paul City Ry. Co., 79 N. W. Rep., 1043.)

MASSACHUSETTS.—Obstructing Streets—Contractors—Injury to Pedestrians—Negligence.

1. A woman walking along a street in the evening, not noticing rails temporarily left in the highway to be placed in defendant's street car track, fell and was injured, though her daughter, who preceded her, passed without accident. There were many lights in the vicinty, but the jury might have found that one of the two lights placed there as a warning had gone out. *Held*, that the question of her due care was properly left to the jury.

2. Defendant's railway was then in operation, and a contractor was taking out the old rails and putting in new ones. There was no evidence whether the contractor was acting independently or as employee of the railway company, but defendant, within whose peculiar knowledge it was, offered no evidence to prove the relation between it and the contractor. *Held*, that the evidence justified a finding that defendant was responsible for the rails being there. (Slayton vs. West End St. Ry. Co., 54 N. E. Rep., 351.)

MINNESOTA.—Negligence—Evidence.

1. In an action for damages for the death of plaintiff's intestate, caused by the alleged negligence of the motoneer of one of defendant's cars, *held*, that the evidence was conclusive that the deceased was guilty of contributory negligence.

2. Also, that there was no evidence that the motoneer was guilty of any wanton or willful negligence in failing to make proper efforts to avoid injury after he discovered the deceased in a place of danger. (Gagne vs. Minneapolis St. Ry. Co. et al., 79 N. W. Rep., 671.)

MINNESOTA.—Injury to Passenger.

Plaintiff, a street car passenger, signaled for the car to stop so that she might alight, and as it commenced slowing up she went upon the lowest step of the car, and stood there for a moment, while the car was slowly moving, holding on to the car rail to steady and protect her from falling, when the car, before stopping, started forward with a jerk, and threw her to the ground, whereby she sustained personal injuries. *Held*, that the defendant's negligence and the plaintiff's contributory negligence were questions for the jury. Saiko vs. Railway Co., 69 N. W. 473, 67 Minn. 8, distinguished. (Currie vs. Mendenhall, 79 N. W. Rep., 677.)

MINNESOTA.—Collision with Fire Department—Contributory Negligence.

1. *Held*, the duties of a member of the city fire department, when driving fire apparatus on a call to fire, may require him to take risks which it would be negligence for a private person to take in pursuit of his private business.

2. In an action by such a member against a street railway company for damages for an injury to him resulting from a collision, at a street crossing, between a street car and a hook and ladder truck driven by him, *held*, that the question of defendant's negligence and of his contributory negligence were both for the jury. (Warren vs. Mendenhall, 79 N. W. Rep., 661.)

NEW JERSEY.—Punitive Damages—Torts of Servant.

1. A principal, whether an individual or a corporation, cannot be charged with punitive damages for the illegal, wanton, or oppressive conduct of a servant, unless the principal participated in the wrongful act of the servant, either expressly or impliedly, by his conduct authorizing or approving it either before or after it was committed.

2. Punitive damages are in the nature of a penalty, especially designed as a punishment for the wanton conduct or malicious motives of a tort feasor, and can lawfully be imposed only when the reprehensible act is brought home to the defendant. (Forhman vs. Consolidated Traction Co., 43 Atl. Rep., 892.)

NEW JERSEY.—Injury to Passenger—Negligence—Riding on Platforms—Contributory Negligence.

1. The occurrence of a sudden lurch or jerk of a street railway car, of sufficient violence to throw a passenger off the platform, who was there preparing to alight, and awaiting the stoppage of the car for that purpose, justifies an inference of a breach of duty

upon the part of those operating the car, within the maxim "Res ipsa loquitur." Traction Co. vs. Thalheimer, 37 Atl. 132, 59 N. J. Law, 474. That the car was following another closely, which was stopping and starting suddenly, is a fact for the consideration of the jury, in determining the cause of the sudden lurch or jerk, and as bearing upon the questions of negligence arising in the cause.

2. It is not negligence per se for the passenger to ride upon the platform of an electric street railway car, nor to get up and go there from inside the car before the car has stopped, to await an opportunity to alight.

3. The railway company operating such a car is bound to exercise a high degree of care to carry its passengers safely in or upon whatever part of the car they are permitted to ride.

4. Whether a passenger riding upon a platform, or standing there awaiting an opportunity to alight, while the car is moving, should, in the exercise of ordinary care for his own safety, take hold of the hand rail there, is a question which, under all the circumstances, must be determined by the jury.—(Scott et al. vs. Bergen County Traction Co., 43 Atl. Rep., 1060.)

NEW YORK.—Collision Between Street Cars—Contributory Negligence of Motorman.

1. Under a rule of defendant, a street railway company, if a car going east after starting from the station was found to be defective it was to be brought back to the station over the west-bound track. About 5 o'clock on a morning that was so foggy that a car could not be seen more than 15 ft. or 20 ft. distant, a car going east was started on the east-bound track, and after it had gone about a half of a mile the motorman found it had no fender; and, instead of returning on the east-bound track, he proceeded 2 miles to a switch, and returned over the west-bound track. About twenty minutes after five, another car, with a conductor and a motorman, was started from the station, going east, over the west-bound track. As to whether this was by order of the train dispatcher, the evidence was conflicting. Both the conductor and the motorman knew of the rule stated. The car was proceeding at the rate of 4 miles an hour, the motorman ringing the bell continually; and when it had gone about 2 miles he saw the headlight of the returning car about 15 ft. in front of him, and when too late to prevent a collision by which he was injured. Held, that the proximate cause of the accident was the negligence of the conductor and motorman in taking out the car on the wrong track on a densely foggy morning, and that the company was not liable.

Conductor and Motormen Fellow Servants.

2. The conductor and motorman on an electric car are fellow servants, and the negligence of the former is imputable to the latter.—(Savage vs. Nassau Electric R. Co., 59 N. Y. Suppl., 225.)

NEW YORK.—Injury to Children—Negligence.—A boy of six, of average intelligence, was permitted by his mother to play after dark on the street in front of the house, under her control. The father was on the opposite side of the street, and the boy, while his mother was temporarily in the house, and the father was not watching, started from the curb to cross to the father. The place was 50 ft. to 60 ft. from the crossing, and a street car, 37 ft. to 75 ft. away, was approaching at about six miles an hour, its usual rate in that locality. The curb was 18 ft. from the track, and the view of the car was unobstructed. The boy struck the car at the edge of the fender or the dashboard, and was injured. The motorman was prudently operating the car, and stopped it in 20 ft. *Held*, that the company was not liable. (Adams vs. Nassau Electric Ry. Co., 58 N. Y. Suppl., 543.)

NEW YORK.—1. Injury to Employee—Contributory Negligence.—An employee of an electric railway company, who while accompanying a flat car a short distance in the discharge of his duty, rides thereon instead of on the motor car, which is designed for the accommodation of passengers, cannot, as a matter of law, be said to be guilty of contributory negligence, if injured while so doing.

2. Same.—Nor can he be said to have been guilty of contributory negligence, as a matter of law, for sitting on a corner of the car, so that one of his legs was between the flat car and the motor.

3. Same—Obligation of Master.—It is the duty of the master to exercise reasonable care in furnishing safe and suitable appliances for the servant to work with, and the servant has a right to rely on the discharge of this duty.

4. Same—Notice of Defect—Character Thereof.—In an action to recover for personal injuries, evidence that an accident was due to the sudden falling off of the brake shoes of a car shows such a defect as would authorize the jury in finding that the defendant, in the exercise of reasonable care, should have had notice thereof.

5. Same.—In an action by an employee to recover for personal injuries, evidence that an accident was due to the sudden falling off of the brake shoes of a car shows a defect of which he, being temporarily engaged with the car, could not reasonably be supposed to have notice. (Butler vs. New York & Q. C. Ry. Co., 58 N. Y. Suppl., 1061.)

NEW YORK.—1. Damages—Injury to Vehicle—Cost of Repairs.—Evidence of the cost of repairing a vehicle injured by the alleged negligence of defendant is insufficient, as a basis of damages, without further evidence that such cost was the reasonable worth of the necessary repair.

2. Same—Usable Value of Vehicle.—While the usable value of a coach, for the period during which it was being repaired, is a proper element of the damages accruing from the injury to the coach, yet the evidence of such value must not be so uncertain as to require the jury to guess and speculate. (Volkmar vs. Third Ave. Ry. Co., 58 N. Y. Suppl., 1021.)

NEW YORK.—Driving Across Track—Contributory Negligence.—Where a driver of an express wagon attempted to cross car tracks on a street where the company's cars had the right of way, and when a car was only 100 ft. away, and, finding his mistake, attempted to get over by whipping his horse, but too late, he was guilty of contributory negligence. (Reiss vs. Metrop. St. Ry. Co., 58 N. Y. Suppl., 1024.)

NEW YORK.—Appeal—Review.—Where, in an action for collision on a highway, plaintiff's servant testified to circumstances from which his freedom from contributory negligence and defendant's servant's negligence might be found, despite the latter's contradictory statements, a judgment for plaintiff should not be disturbed. (Seaman vs. Metropolitan St. Ry. Co., 58 N. Y. Suppl., 1053.)

NEW YORK.—Carriers—Injuries to Passengers—Sufficiency of Evidence.—Plaintiff testified that the street car started suddenly while she was alighting, throwing her to the ground. The conductor, the motorman, and three passengers testified that the car came to a full stop before plaintiff attempted to alight, and that it made no movement until after she had fallen. *Held*, that a judgment for plaintiff would be reversed. (Hart vs. Metropolitan St. Ry. Co., 58 N. Y. Suppl., 1088.)

NEW YORK.—Appeal—Review—Excessive Damages.—Unless it is manifest that the verdict in an action for personal injuries was the result of passion, prejudice, or corruption, it will not be disturbed as excessive.

2. Same—Error Cured.—In an action for personal injuries, the defendant moved to strike out the value of the doctor's services. The court denied the motion, saying, "I will deny the motion, but she [plaintiff] cannot recover for it here," but charges that there was no evidence of payment to physicians sufficient to warrant recovery for medical services, and that the doctor's bill was eliminated from the case, were given at the close of the case. *Held* that, if there was error in denying the motion, it was cured by the subsequent charges. (Polak vs. Metropolitan St. Ry. Co., 58 N. Y. Suppl., 1133.)

NEW YORK.—Elevated Station in Street—Right to Erect.

1. A street railway company cannot erect an elevated structure in a street for the storage of its cars or accommodation of its trainmen, to the injury of an abutter.

Same—Cleaning Cars in Street—Injunction.

2. Where a street railway company's charter prohibits it from washing its cars in a street, an abutter may have it restrained from so doing.—(Waldmuller et al. vs. Seaside & B. B. El. R. Co. et al., 58 N. Y. Suppl., 7.)

NEW YORK.—Negligence—Question for Jury.—Plaintiff was knocked down by a cable car, and, after being dragged some distance, was run over. The gripman, who was an inexperienced man, testified that the car was stopped almost as soon as plaintiff was struck. A number of the witnesses who saw the accident contradicted the gripman's statement that the gong was rung, and also testified that the car went about 75 ft. after plaintiff was struck. An expert witness testified that the car could have been stopped within 25 ft. *Held*, that the question whether there was negligence in not stopping the car sooner should have been left to the jury.

2. Same—Effect of Contributory Negligence.—Although plaintiff was negligent in being struck by defendant's car, he may recover, if his injury was caused by defendant's subsequent negligence in failing to stop the car in time after he was struck. (Green vs. Metropolitan St. Ry. Co., 58 N. Y. Suppl., 1039.)

NEW YORK.—1. Carriers—Defective Appliance—Curtain Rods—Liability.—An open electric car was provided with curtains, at the bottom of which was an iron rod, with brass shoes on each end, which worked in a groove. On the day of a high wind, when the curtains were pulled down on the windward side, a shoe broke where it was inserted into the rod, and the end of the rod struck and injured plaintiff, a passenger. The break was clean, and showed no flaw. The car was built and the curtains put in by a firm of high standing in 1895, and the car had been used only dur-

ing the summers of 1895 and 1896. Similar curtains were in general use on a great many other roads. No similar accident was shown, and there was evidence that none such had occurred on defendant's road. It was not shown that the rod had ever been examined. *Held*, that defendant is not liable.

2. Same—Degree of Care.—An electric railway company is not bound to use the highest degree of care in respect to the curtain rods of its cars. (Leyh vs. Newburgh Elec. Ry. Co., 58 N. Y. Suppl., 479.)

NEW YORK.—Injuries to Passengers—Contributory Negligence.

1. Plaintiff signaled a street car approaching the crossing on which he was standing to stop, and it slowed down, but did not stop completely, whereupon he attempted to board it while in motion, and after it had passed the crossing, and in doing so was injured. It did not appear that the slowing down of the car was in response to plaintiff's signal. *Held*, that plaintiff was guilty of contributory negligence.

Same—Failure to Stop for Passenger—Negligence.

2. A street car, on being signaled to stop, merely slackened its speed, without stopping, whereupon plaintiff attempted to get on it while in motion, and was injured. There was no evidence that the car had slowed down in response to the signal, or that the conductor or motorman knew of the attempt to board it. *Held*, that a finding in an action to recover for such injuries, that the persons in charge of the car were negligent, was not warranted. —(Reidy vs. Metropolitan St. Ry. Co., 58 N. Y. Suppl., 326.)

NEW YORK.—Injuries to Passengers—Defective Appliances.

A finding by a jury that a construction by a railroad company of overlapping swinging doors leading to a platform that was used daily by several thousand persons, and was long enough to enable the company to build doors, so that they could not overlap, was negligence, so as to justify a recovery by a passenger injured thereby, will be sustained; it being the company's duty to furnish its patrons with reasonably safe means of ingress and egress to and from the platform.—(Kiernan vs. Manhattan R. Co., 58 N. Y. Suppl., 394.)

TEXAS.—Damages—Personal Examination.

Where plaintiff in an action for personal injuries has exhibited them to the jury, and physicians have testified in relation to them, defendant is entitled to have an examination by experts of its own selection.—(Chicago, R. I. & T. Ry. Co. vs. Langston, 51 S. W. Rep., 331.)

NEW YORK.—Collision Between Electric Cars—Injury to Passenger.—An electric car, running at a high rate of speed, came into collision with a car on a parallel track, which had collided with a beer wagon a few seconds before. There was no evidence as to the manner of operating the car which collided with the beer wagon, nor as to who was answerable for such car being thrown on the track of the car on which plaintiff was a passenger. The distance between the cars at the time of the first collision was about 150 ft., and the interval of time about five seconds. *Held* to justify a finding that defendant was not guilty of negligence. (Snediker vs. Nassau Electric Ry. Co., 58 N. Y. Suppl., 457.)

NEW YORK.—Evidence—Expert Testimony.—In an action against a street railway for injuries to a child three years old, it appeared that the motorman was justified in believing that the child would cross the track safely, until the car was within 20 ft. of the child. At this distance the motorman applied the brake, and stopped the car within 20 ft. to 25 ft., but not in time to prevent the accident. An expert witness called by plaintiff testified that, by proper application of the brake, the car could be stopped within a distance of from 20 ft. to 25 ft. *Held* that, as the evidence was competent and material to issue, it was error to strike it out at the request of plaintiff. (Frohle vs. Brooklyn Heights Ry. Co., 58 N. Y. Suppl., 561.)

NEW YORK.—Damages—Personal Injuries. In an action for personal injuries, an instruction that, if the jury found for plaintiff, he was entitled to recover what would be his reasonable expense incident to his condition in the future, is erroneous, where there is no evidence as to what he would be required to pay because of his injuries in the future. (McKenna vs. Brooklyn Heights Ry. Co., 58 N. Y. Suppl., 462.)

PENNSYLVANIA.—Accident to Passengers—Instructions.

1. There being conflicting evidence as to whether a passenger got off a street car before it stopped, or did not leave it till it stopped, and it started with a sudden jerk while she was getting off, causing her to fall, and nothing to take the case out of the rule that it is negligence for a passenger to alight from a moving train, it is error to charge that, if the jury take the version that the car had not stopped when she undertook to get out, they might find her guilty of contributory negligence, and in that case she would not be entitled to recover, and that, if she undertook to get off the car before it stopped, they might ascertain that she ought to have waited.

2. There being no evidence that the car was going so slowly as to be substantially stopped when the accident occurred, it is error to introduce that element into the answer to a requested instruction.—(Neff et al. vs. Harrisburg Traction Co., 43 Atl. Rep., 1020.)

PENNSYLVANIA.—Carriers—Injury to Passengers—Evidence.

An electric car on an up grade stopped, and could not be moved. An employee of defendant (though in what capacity it did not appear) gave instructions to the motorman, sanded the track, and, when all attempts to move the car proved futile, told the motorman that he would procure another car, which he did. In bringing up the relieving car, from some cause it ran into the disabled car, and injured a passenger. Held, that the burden was on defendant to rebut the presumption that the injury was by its negligence, by showing that such employee on the relieving car was a mere intruder, acting without authority.—(Madara et ux. vs. Shamokin & Mt. C. Electric Ry. Co., 43 Atl. Rep., 995.)

PENNSYLVANIA.—Contributory Negligence — Non-suit.—A woman stopped at the curb of a street, and looked before attempting to cross. The trolley car that subsequently struck her was then approaching at a distance of 185 ft. She stood there "some time" after looking, and while crossing the track she was struck. The evidence was conflicting as to the speed of the car and its distance from the woman immediately before she stepped on the track. *Held*, that the question of contributory negligence was for the jury. (McGovern vs. Union Traction Co., 43 Atl. Rep., 949.)

TENNESSEE.—Appeal—Objections—Harmless Error—Trial —Instructions—Negligence of Motorman.

1. An objection to the admission of evidence cannot be first raised on appeal.

2. A charge that it is the duty of a motorman to keep a vigilant lookout for children on the street, and upon the first appearance of danger, or probable collision with a child, to stop the car in the shortest time and space possible, does not impose too great a degree of care on the motorman, where it is charged, in the same connection, that he is bound to act only as a man of ordinary prudence.

3. In an action for death by negligence, the court said that it was natural for the jury to have their sympathies aroused, and that "this [was] entirely proper," but that, as jurors, they must not forget their duty to render a verdict according to the law and the evidence, and also cautioned them not to allow their sympathy to affect their verdict. *Held*, that there was no reversible error.

4. Special requests need not be given, when they are embodied in the main charge. (Citizens' St. Ry. Co. vs. Dan, 52 S. W. Rep., 177.)

TENNESSEE.—Negligence—Street Crossing Accidents—Contributory Negligence—Burden of Proof.

1. In an action for negligence, the burden of proof is not on plaintiff to show affirmatively that he was exercising ordinary care.

2. In action for personal injuries, brought by one who was run down at a crossing by a vehicle, a charge that defendant might presume that any one crossing the street would see the way in which he was using it, and not attempt to use it right in front of him, so as to make it impossible for him to avoid a collision, is erroneous, as ignoring the circumstances of the collision, and the rate of speed at which defendant was driving. (Burke vs. Citizens' St. Ry. Co. et al., 52 S. W. Rep., 170.)

TEXAS.—Speed—Instructions—Evidence.

1. In an action to recover for damages occasioned by a collision with one of defendant's street cars, it is not error to charge that it is negligence to run its cars at a greater rate of speed than is allowed by ordinance.

2. Error cannot be predicated on a part of a charge where, when considered as a whole, the charge fully protects appellant's rights.

3. In an action for damages resulting from a collision with a street car, it is not error to permit a witness to state that "the car was going faster than any horse and buggy would travel over a good road at any kind of a trot," as the latter fact is a matter of common knowledge and observation.

4. In an action to recover for personal injuries sustained by reason of a collision with a street car, testimony that witness saw plaintiff a few days after the accident, and that he was limping, is competent, as showing present pain.

5. In an action to recover for personal injuries, the admission of testimony "that witness saw plaintiff a few days after the accident, at a place other than plaintiff's home, and that plaintiff said he was hurt, and wished that he had not come," is harmless error where the fact that he was hurt is not controverted, and the verdict is not complained of as excessive.

6. Where the evidence shows that there were two people in the wagon at the time of the accident, testimony by the motorman that "they said they did not blame" him is incompetent where

offered as a part of the res gestæ, and it is not shown that it was plaintiff who spoke the words.

7. Where it is shown that the mules drawing the wagon in which plaintiff was riding were frightened, and ran in front of the car, testimony that there was nothing indicating that they were going on the track was properly excluded, as calling for the conclusion of the witness.—(City Railway Co. vs. Wiggins, 52 S. W. Rep., 577.)

Patent Decision

A decision was rendered Nov. 10 in the United States Circuit Court of the Eastern District of New York in the case of the Thomson-Houston Electric Company, against the Nassau Electric Railway Company. The suit was brought on claim of infringement of the Elihu Thomson patent on magnetic blow-out issued to the plaintiffs in 1883, and is of particular interest from the fact that the defendants were using the apparatus of the Lorain Steel Company. The decision which was rendered by Judge Thomas was in favor of the defendants on the ground of wanting of novelty in the invention.

Judge Thomas also rendered a decision the same day in the case of the Sprague Electric Railway & Motor Company vs. the Nassau Electric Company, for alleged infringement of patent 324,892, issued to F. J. Sprague on Aug. 25, 1885, relating to the suspension of electric motors under cars. The judge considered that the defendant in its equipment infringed claims 2 and 6 of this patent, and stated that the complainant should have a decree enjoining the defendant from infringing these claims.

The Distribution of a Fare

At a meeting of the Metropolitan Street Railway Association, composed of employees of the Metropolitan Street Railway Company, held Nov. 4, President Vreeland, of the company, delivered an address to his men concerning management and operation. "To the minds of people like us," said he, "engaged in a business the financial foundation of which is a five-cent piece, the mention of millions of dollars really conveys only a dim idea. There is a certain point at which the mind loses grasp of the significance of figures; it is like talking of the vast interstellar spaces. We know they are very great and we let it go at that. When it comes to five cents, though, that is right in our line, and in order to bring within the understanding of every one just how each five-cent piece you men collect is divided, I have made the following analysis from the company's records to show where we stand with the capitalists who own the property we operate. You will observe they do not get much the best of us on the divide, for this is how the nickel is distributed:

Labor	.0195
Material	.0048½
Taxes	.0026½
Interest	.0144
Total	.0414
Leaving for stockholders	.0086
Total	.0500

"The fact that less than seven-eights of one cent out of every fare goes to the owners—in other words, the stockholders of the property—will, I doubt not, be interesting to a great many public instructors, who continually discuss the railroad business as one where there is nothing but income to embarrass the management. Another interesting fact was developed in this investigation of mine, and that was that out of every dollar spent in operating the Metropolitan system, 80 cents went for wages, and only 20 cents for material."

Street Railways for Removal of Refuse

H. S. Beattie, treasurer of the Metropolitan Street Railway Company, of New York, contributes in the last issue of the "Municipal and Railway Record" an article on this most interesting subject. Mr. Beattie states that he does not care to say how practicable such an undertaking as the transportation of express over the the lines of his company, after they are all operated by mechanical power, would be, but strongly advocates the employment of street railway cars to carry off ashes, garbage, snow, ice, etc. Mr. Beattie's plan is to have a sufficient number of vans operated over the railway lines to one dumping place. Taking New York as an example, he says in part: "All the details of this plan, from the loading of the vans, at the point of collection, to the automatic dumping of their contents into sea-going, self-dumping scows, at the chosen central, single dumping station, received the unqualified indorsement of practical men, every one of them an authority in transportation matters, prior to the introduction of cable or electric power. How much easier of accomplishment should it now be, when the Metropolitan Street Railway and Third Avenue Railroad companies are operating over 120 miles of their lines by mechanical power! How much easier still will any such undertaking be, when the horse shall no longer be used by any railroad in the city, when the conditions that must obtain under an ideal system of underground electric traction shall have been realized, and each car of a line may be operated as independently of another as if they ran on separate tracks.

"The withdrawal of over 300 horses and carts from the most congested strips of the streets of New York during the busiest hours of the day is in itself a benefit, the commercial value of which would require many figures to express.

"The water front of the city is more valuable than that of any known maritime municipality. The annual rentals paid by most of our shipping interests run up into the tens of thousands of dollars. Yet thirteen of the most desirable locations on the East and North Rivers are abandoned to the uses of the Department of Street Cleaning as dumping stations, when one would be sufficient. Considering the rental value of these dumping stations were they released to the commerce of the port, and the depreciation in value which their existence occasions to the property adjacent to them, it is safe to state that the city treasury would be the beneficiary by their abolishment to the extent of not less than $1,000,000 per annum. And this amount would not be diminished by any increase of expenditure as a consequence of the proposed change in method. On the contrary, there should be a saving of one-third in the cost of carting, or not less than $250,000 per annum, if the appropriation for that item of the work of the department for the year 1895 is to be as large for 1896 and succeeding years.

"Furthermore, the cost of final disposition for the current year, considerably over $400,000, should be reduced at least one-half, through the concentration of the scows and steam tugs of the department at one point; the rentals paid for hired scows would be rendered unnecessary by the almost instantaneous loading of those vessels, to fill some of which now requires more than two days by the ordinary cart dumping method."

New Construction at Staunton, Va.

R. D. Apperson, general manager of the City Street Car Company, of Staunton, Va., advises us that his company is figuring on building a new car house and power station with steel-trussed roofs, one 50 ft. x 100 ft., the other 30 ft. x 115 ft., arranged for slate covering. The company also wants prices and all information at once for shafting, clutch pulleys, clutch couplings, bells and mechanical draft.

New Traffic Arrangements in Brooklyn

The Brooklyn Rapid Transit Company, which controls all the street railway and elevated lines in Brooklyn, with one exception, has just placed in operation a system for the interchange of traffic between the elevated and surface lines, the like of which is to be found in no other portion of the United States. The congested state of traffic on the surface lines had been bothering the officials of the company for some time prior to the acquisition of the elevated railroads in January, and since that time they have been strenuously wrestling with this weighty problem. On Nov. 1, a system of transfers was finally put in operation which gives promise of accomplishing this task. The system provides that all long distance riders, particularly those to the suburbs, use the elevated trains for transportation to their termini, after which a transfer is given to the surface lines if the passenger desires to continue further. It is also practically obligatory for the passenger to patronize the elevated roads as a second fare is charged on the surface cars which parallel these lines and heretofore carried passengers direct to the suburbs for a single fare. In returning from the suburbs the same methods are in vogue, thus when a passenger reaches the termini of the elevated lines he is given a free transfer to the elevated, but if he desires to continue the entire distance by the surface cars, he is required to pay an additional fare. The system will be of advantage to the long-ride passenger, as the elevated railways make better time than the surface cars within the congested district. It will also be of advantage to the short-haul passengers, for by the time a car had reached the city proper, under the old method, there was little chance of the short distance rider securing a seat.

Test of 300-kw. Units at Richmond

In a paper presented at a meeting of the American Institute of Electrical Engineers, in New York, Nov. 22, E. J. Willis, superintendent and engineer of the Richmond (Va.) Traction Company, gave some figures of a test made by him March 30, 1897, of two 300-kw. direct-connected railway units at different loads The equipment tested is described below:

Card Numbers.	Time.	Boiler Pressure.	Receiver Pressure.	Vacuum.	Feed Temperature.	Throttle Temperature.	Injector Temperature.	Overflow Temperature.	Draught Flue Temperature	R. P. M.	Mean Pressure H. P. Cylinder.	Mean Pressure L. P. Cylinder.	Volts.	Amperes.	Water Feed.	Coal Feed.

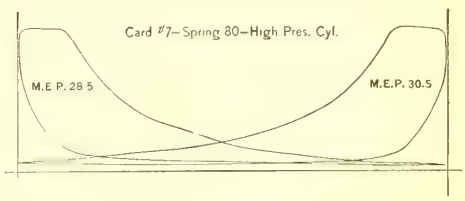
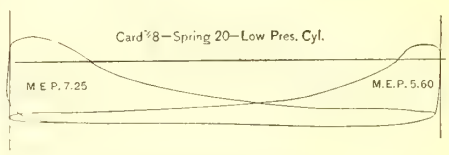
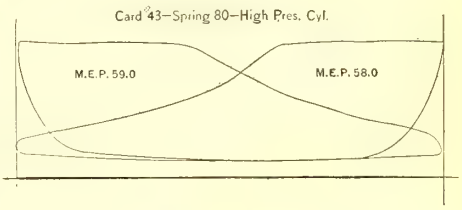
Boilers.—One 300-h.p. Campbell & Zell water-tube boiler with 3000 sq. ft. submerged heating surface.



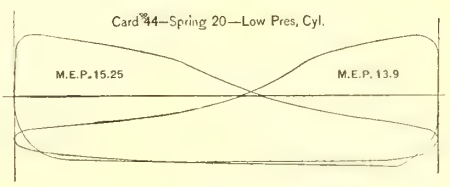
Engine.—16-in. and 30-in. x 42-in. Hoover, Owens & Rentschler horizontal tandem compound condensing engine, double eccentric, 100 r.p.m.



Generator.—300-kw., six-pole, steel-frame General Electric railway generator.



Piping.—The piping is practically what is known as standard, being an 8-in. spring from boiler to 14-in. steam-header and 6-in. spring from steam-header to throttle. A short 14-in. exhaust pipe exhausts through a Hartford heater into a Deane jet condenser.



A large water rheostat was provided, capable of handling the full output of the generator, and a Weston ammeter and voltmeter were placed upon the circuit of the generator. By this means the output of the generator could be fixed, maintained and measured at any desired point. The system of piping permitted the feed-pump and condenser to be operated by a separate boiler, so that all the steam generated by the boiler passed through the engine. All valves were tested and made tight. A Worthington hot-water meter was thoroughly overhauled before the test and was accurately tested before and after the run. The water and steam consumptions are those given by this meter. The coal fired during the test was Pocohontas run of mine, giving probably 13,000 B. T. U. The draught at the grate during the run was 5/8 in. Indicator cards were taken as nearly every fifteen minutes as possible off both ends of each cylinder, and also simultaneous readings of coal, water, electrical output and the other items mentioned in the table. Sample cards are shown herewith. The object was to determine the steam, water, coal consumption and indicated horse-power of this unit at different loads. The load was as follows: For one hour at 200 amps., the next hour at 300 amps., and so to 500 amps. It was intended to place the load the next hour at 600 amps., but the machine became too warm, and instead the load was continued for two hours at 500 amps.

It is regretted that the point of load could not be carried higher, but it is to be remembered that railway generators are usually designed for fluctuating loads, and that such a steady loading as given in this test is likely to cause considerable heating. It is further unfortunate for the sake of accuracy that on account of the need of the generator for the operation of the load, the duration of each test could not have been made greater, since the determination of coal and water consumption for such short periods of time is almost always attended with unavoidable inaccuracies. The water rheostat was composed of two sheets of boiler plate 5 ft. x 6 ft. each. By means of soda the conductivity of the liquid was brought to the desired point. With light loads and before the water commenced boiling completely there was some fluctuating in amperage, but after the water got to boiling thoroughly the load could be maintained perfectly steady. At 500 amps. there was

about 15 sq. ft. of each plate submerged. The water evaporated by the boiling was replaced by a hose connection and the water level in the rheostat tank thereby maintained constant. The writer would state that in his experience with rheostats of any size, if a steady load is required, it is better to let the water come to a boil and the plates remain steady, replacing the evaporated water with a running connection, than to attempt the continual raising and lowering of the plates.

This test was made to confirm the writer's opinion that it is advisable with railway units carrying fluctuating loads to install a double eccentric undersized engine, and that better running economy can thereby be obtained than by the installation of the usual larger and more expensive engine. It will be noticed that the engine gave its best steam economy at about 400 amps., and as the average load on this engine is lower than this, the wisdom of the installation for this plant of so small an engine for the 300-kw. units is plainly shown.

The Design of Fusible Cut-outs *

BY B. H. GLOVER

The simplest, and therefore most common, method of protecting electrical circuits is by means of the fusible cut-out. While much might be said about circuit breakers, switches and special combinations for opening and controlling circuits, the object of this paper is not to enter into a discussion of the relative merits or proper adaptation of these fittings, but simply to put before you some facts demonstrated by exhaustive tests and extended practice, and from this information and experience derive a few conclusions regarding the proper design of fusible cut-outs.

That the present cut-outs are not entirely satisfactory goes without saying. If they were the subject of this paper would not have been suggested.

It is a strange characteristic of this age of progress that sometimes the most common and necessary articles are accepted in the crude, and often unfinished, form in which they have originated, and are apparently forgotten and neglected in the mad rush for something new or strange. The return swing of the pendulum is, however, inevitable, and we now hear of new forms of arc lamps and renewed interest in the perfection of various forms of lamps depending on the incandescence of heated conductors or metallic oxides. The thermal cut-out is still one of the most unreliable of the many devices employed on electrical circuits. Its use is universal, but beyond a few practical details the device is but little understood. Such improvement as has been made has largely been due to the vigilance of the various insurance boards. As a source of vexation and uncertainty the fusible cut-out is probably unrivaled.

Speaking from the standpoint of the fire underwriter, the proper design of cut-outs is an important subject, inasmuch as a very considerable fire waste has been, and continues to be, occasioned through the faulty construction and design of these fittings. All tests and treatments have shown the common cut-out to be subject to such variations and modifying influences that but little of practical value can be deduced from analytical investigations.

A cut-out may be said to consist of three principal parts—(a) the base and its cover, (b) the terminals, and (c) the fuse. These will be taken up in the order given so far as is possible.

(a) In the earlier days of electric lighting wooden bases were used, but were soon abandoned, due to continual trouble with "grounds" and "shorts," resulting from absorption of moisture and the loosening of contacts and charring due to the combustibility of the wood. Porcelain is now almost universally used. The base and cover being much the larger portion of a cut-out, the porcelain manufacturer has taken it upon himself to design and sell these goods. Important electrical details are often sacrificed for convenience in getting out the porcelain, and "any old thing will go" seems to be the motto followed in some cases, no regard being paid to the various and excessive demands made upon the product. It is poor practice to use short fuses in order to economize in porcelain.

The quality of porcelain used and its glazing is seldom given any consideration by contractors or engineers except, perhaps, for use with very high potentials. The subject of glazed and unglazed porcelain in itself opens up a large field for discussion. A glaze with an excessive coefficient of expansion will in time become full of cracks or become "crazed," as the porcelain manufacturers express it. These cracks retain moisture and offer paths of comparatively low resistance between terminals of opposite polarity or to ground.

The use of lead in the glaze usually results in a metallic film upon the blowing of a fuse. The parts of a cut-out about the fuse itself should preferably be left unglazed. The fuse should not be in contact with any surface of the base. If supports between the terminals are necessary they should be in the form of traverse ribs with smooth rounded tops.

While an air space is desirable about the fuse the ends of the block should not be left entirely open. As a fuse usually ruptures at or near the center, the aim should be to provide a proper vent at this point and still retain sufficient pressure to cause a blow-out of the metallic vapors and suppression of the arc formed. For these reasons a rather restricted air space at the ends and an enlarged air chamber with vents, near the center of the fuse gives more reliable action. A cover for the base should always be used. The fire risk is made less and the sensitiveness of the fuse is thereby increased, especially for small fuses.

(b) Terminals are universally made of brass in the form of stampings, castings or sections of square or round bar. The following modes of connection to the wires have been noted: a screw and washer, a screw with one upturned lug on terminal, with and without washers; a set screw, two set screws, an angular bottom piece with a clip above, held by one or two screws; double clips with a center V groove, and several others.

In the construction of switches it is considered quite proper and necessary to provide lugs, firmly bolted to the switch, into which the conducting wires shall be soldered. This applies to switches of over 25 amps. capacity. If for switches and bus-bars and in making connections to dynamos and motors, why not for cut-outs?

Connections for currents up to 25 amps. should be made to terminals provided with screws and washers with a turned-up lug on both sides to prevent this wire from slipping out. When the capacity of the cut-out exceeds 25 amps. connections should be made with lugs firmly screwed to the terminals on a flat surface, and into which the conducting wires can be soldered. This may seem like excessive care, but when it is considered that very appreciable losses are due to the many poor contacts and connections made in a circuit, too much attention cannot be given to this matter of contacts. The terminals should be set in from the ends of the blocks so that live portions of the circuit will not be exposed. The proper distance between terminals has long been a disputed question.

A catalogue of a well-known manufacturer of these goods shows, for 110-volt circuits, break distances of from ¼ in. to 2½ ins. He no doubt strikes an average somewhere.

An engineer of a prominent company stated two years ago: "We are redesigning our link cut-outs so that the fuse metal tips shall be fully 1 in. apart. Some of our cut-outs are much less than this, and we believe it is safer to have a longer break distance than what we are now using." A Chicago engineer, whom you all know, said a few years ago: "I have always felt that the emphasis of experimental evidence should be directed to convincing the people of the advisability of using long fuse blocks, thereby contributing to the reliability of such protecting devices."

This is all reliable testimony, and should be given careful consideration, not only by manufacturers, but by contractors and engineers as well. There are many goods on the market with a ½-in. break distance between terminals.

A current of 20 amps. will invariably establish a vicious arc between terminals at this distance, and the terminals will frequently melt with explosive violence. The terminals are not only fused, but often the entire base and cover are shattered into fragments. Such results are aggravated by the enormous capacity of our modern stations in populated districts. For a given fuse, blown in a given time there is a critical length. Careful experiments have shown these lengths to be as follows:

	Inches
For 3-5 amps	2½
For 10-15 amps	3½
For 20 amps	4

Or for each 5 amps. an increase in length of ½ in. These lengths seem excessive when judged by common practice, but the data clearly indicate where practice might be improved.

Realizing that extended reforms cannot be instituted at once, the rules of the National Electrical Code specify 1¼-in. break distance between terminals for 110 volts, and 2½ ins. for 220 volts, the fuses to be held free from contact with the base and be provided with tips of hard metal. In the open type of cut-out the terminals usually have a greater distance between them than in the covered style, but a serious fault in their design is that the terminals are set in flush with the surface of the porcelain. Terminals should be secured to the base by at least two screws, so as to prevent turning and loosening. Screw-heads on the back should be countersunk and the heads covered with a moisture-proof and insulating wax or compound. These points should go without saying, but an inspection of stock being sold shows that there is neglect along these lines.

* Paper read before the Chicago Electrical Association, Nov. 17, 1899.

(c) The ordinary fuse is made from an alloy, the greater part of which is lead. This alloy is used in the form of wire, wire links or strips. The opening of the circuit is caused by the melting of the fuse. The necessary heat is obtained from the energy developed in the fuse by the current. But the blowing of a fuse is not immediately an electrical act. The current fuses the metal, the cross section is reduced at some point due to gravity, unequal expansion or "sweating," the heat intensifies at this point and a globule falls, breaking the circuit and establishing an arc, which soon burns out a length of the fuse. The time required for this action may vary between considerable limits under different conditions. In some cases this fact is an advantage, while in others it might be fatal.

A combination intended to increase the accuracy of operation and to reduce to a minimum the radiation and conduction of heat is found in the enclosed fuse.

A fibre tube is filled with a porous powder and the fuse is soldered to the brass ends of the tube, being imbedded in a powder except in the center of the tube, where a small capsule forms an air chamber. These fuses will operate at a predetermined point for any overload, and can be relied upon within very close limits. An objection has been made to their use, as there is no exterior indication to show when a fuse has opened. A new design is about to be put on the market with the object of overcoming this objection. It consists of an inclosed fuse with a shunt of fine high-resistance wire between the terminals on the outside of the fibre tube. The blowing of the fuse diverts the current through the shunt wire, which immediately blows and serves as an outside indicator. Enclosed fuses without the air chamber are not as sensitive or reliable as those with the air chamber.

An ideal fuse would be one that would act at nearly a constant time interval for all currents in excess of its normal. In this respect it would resemble a magnetic cut-out. Its curves would be a straight line from the point of its rated capacity and slightly approaching the vertical axis for all excess currents. In practice the curves of all thermal cut-outs must be more or less modified hyperbolas. The ideal curve could only be obtained were it possible to eliminate conduction and radiation losses. This line of attack should be followed in designing a sensitive fusible cut-out. Small fuses approach this condition to a greater extent than large ones.

For sudden heavy overloads a multiple fuse of several small wires is much more sensitive than one large one of the same capacity. For the same reason a thin, flat ribbon may be considered more reliable than a round fuse.

Invitation to Contractors for the New York Tunnel Railway

The following invitation for bids for the construction and operation of a tunnel railway has been issued by the Board of Rapid Transit Railroad Commissioners of New York City.

OFFICE OF THE BOARD OF RAPID TRANSIT RAILROAD COMMISSIONERS OF THE CITY OF NEW YORK.

The city of New York (hereinafter called the city), acting by its Board of Rapid Transit Railroad Commissioners, proposes to build a rapid transit railroad in the city of New York. By this advertisement the Board invites proposals to construct the railroad, to equip the same, to put the same into operation and thereafter to use and operate the same upon a lease thereof from the city for the term of fifty (50) years with a right to a renewal of the lease for a further term of twenty-five (25) years, all upon the term and conditions set forth in the draft of contract hereinafter referred to.

Payments to the contractor will be made for construction as the work proceeds as provided in the form of contract.

The annual rental to be paid by the contractor under such lease, after completion, will, except as provided in the contract, amount to the interest paid by the city on its bonds for the cost of construction (including interest during construction, but excluding bonds issued to pay for easements and the like), and in addition 1 per cent on such cost of construction with provision for contingent abatement or reduction of such 1 per cent during the first ten years of the lease, and, in addition, if the proposal of the contractors shall so state, in years when the gross receipts from the operation of the road exceed five million dollars ($5,000,000), a sum equal to the percentage of such excess stated in such proposal.

The points within the city of New York between which the said road is to run and the route or routes to be followed are as follows, namely: From the corner of Broadway and Park Row under Park Row to Centre Street, under Centre Street to new Elm Street, under new Elm Street to Lafayette place, to and under Fourth Avenue and Park Avenue to 42d Street, under 42d Street to Broadway, under Broadway to 59th Street, under Broadway (formerly the Boulevard) to 124th Street, then by viaduct to 134th Street, under Broadway and Eleventh Avenue to a point about 1350 ft. north of 190th Street, to the southeast end of Ellwood Street, over Ellwood Street, Kingsbridge Road and Riverdale Avenue to Kingsbridge Station of the New York & Putnam Railroad, together with a loop under City Hall Park and Broadway connecting Centre Street and Park Row, and a branch as follows: Running from 103d Street to and under 104th Street, crossing Central Park, to Lenox Avenue and 110th Street, under Lenox Avenue to 142d Street, easterly to and under the Harlem River, to and under 149th Street to Third Avenue, to and under and by viaduct along Westchester Avenue to Southern Boulevard, to Boston Road and Bronx Park.

The general method of construction shall be such as to provide for the portion of the route on the loop south of the City Hall and for the portions of the route on both the east and the west side lines north of 103d Street, two tracks, and for the portion of the route between the City Hall loop and 103d Street, four tracks. These tracks shall be of the standard gage, that is to say of a width of 4 ft. 8½ ins. between the rails. The roof of the tunnel shall be as near the surface of the street as street conditions will permit, and is to have a height of not less than 13 ft. in the clear and with a maximum width in the clear, except as influenced by local conditions, of 50 ft. where there are four tracks and 25 ft. where there are two tracks. There shall also be suitable stations, turnouts, switches and cross-overs. The portion of the route underground shall be constructed with steel girders, with brick or concrete arches or masonry walls and arched roof. The viaduct portions shall be of steel and masonry. The manner of construction of the portions underground shall be by tunneling or open excavation.

The railroad is, for the purposes of the contract, divided into four sections: Section I, including the part from the southern terminus at the City Hall to 59th Street; section II, including (a) the part on the west side from 59th Street to 137th Street, and (b) the part on the east side beginning with the branch at 103d Street and the Boulevard, and extending to 135th Street and Lenox Avenue; section III, including (a) the part on the west side from 137th Street to Fort George, and (b) the part on the east side from 135th Street to Melrose Avenue; and section IV, including (a) the part on the west side north of Fort George, and (b) the part on the east side north of Melrose Avenue. The city expects that the entire railroad, that is to say, all of such four sections, will be constructed and operated. But the city desires to restrict its entire pecuniary liability for rapid transit at any one time within the limits deemed consistent with its other obligations and interests. The railroad is, therefore, to be constructed and equipped in sections. The contractor shall begin with section I. If and when, within one year after the commencement of work on section I the city shall so elect, the contractor shall construct section II. If and when, after the commencement of section II, and within two years from the commencement of section I, the city shall so elect, the contractor shall construct section III. If and when, after the commencement of section III and within three years after the commencement of section I the city shall so elect, the contractor shall construct section IV. The railroad shall, so far as concerns the rights and obligations of the parties under the contract, be deemed to include only section I, and in addition the other sections II, III and IV, which the city shall determine to construct within the limits of time aforesaid.

The term of years for which the contract is proposed to be made extends for fifty years after the completion of the road and its readiness for operation as declared by the Board, with an option to the contractor to extend the lease for twenty-five years at a rental to be fixed as in the contract provided, but not less than the average rental for the last ten calendar years before the contractor's demand for renewal.

Other requirements, provisions, details and specifications are stated in the printed form of contract now on file at the office of the chief engineer of the Rapid Transit Board, 22 William Street, New York City, where copies of the same and of the forms of bonds and contractor's proposal may be had. Such printed form of contract is to be deemed part of this invitation.

Sealed bids or proposals for the construction and leasing of such rapid transit road indorsed: "Proposals for constructing and leasing Rapid Transit Railroad," with the name of the person or persons, corporation or corporations making the same will be received at the said office of the Board at 320 Broadway, Borough of Manhattan, New York City, until Jan. 15, 1900, at 12 o'clock noon, at which time or at a later date to be fixed by the Board, the proposals will be publicly opened at the said office and the award of the contract, if awarded, will thereafter and within thirty days after the opening of the bids be made by the

Board to the person or persons, corporation or corporations, if any, whose proposal shall, in its opinion, be for the best interest of the city. The bidder or bidders whose proposal shall be accepted shall in person or by duly authorized representative attend at the said office of the Board within ten days after the notice of a delivery by the Board and deliver a contract in the form referred to duly executed.

At the time of the delivery of the contract the contractor shall give security as follows:

(1). By deposit of one million dollars ($1,000,000) in cash or in securities of the character of securities in which savings banks of this State may invest their funds and which securities shall be approved by the Board. Such one million dollars ($1,000,000) shall be security for construction.

(2). By a continuing bond in the penalty of one million dollars ($1,000,000) to secure construction, operation, payment of rental and all other obligations of the contractor.

(3). By a bond in the penalty of five million dollars ($5,000,000) to secure construction and equipment.

[The forms of the bonds are prescribed in the contract, and further provisions follow in the invitation to bid, covering various details connected with the presentation of bids, certification of deposits, etc.]

Notes on Railway Motor Rating

John Lundie, the well-known transportation engineer, has recently contributed the following paper to the "Electrical World and Engineer," which we reproduce herewith, with the kind permission of its editors:

MR. LUNDIE'S ORIGINAL PAPER

The following notes on motor rating comprise a summary of results which the writer had intended to reserve for publication in an extended paper, justifying the somewhat radical statements made, but which are published now, believing they may be of value to others working along similar lines.

The power rating of an electric motor under actual conditions of operation, on either constant or frequent intermittent load, should be directly proportional to the average electrical power input, independently of variations in current, except as maximum current may be governed by commutation.

The sum of the percentages of I^2R losses and core losses at all inputs throughout the range of practical operation can be made practically a constant. In order, however, that a proper balance of heating in different parts of the motors may be maintained, whether the heating be due to I^2R or core losses, the range and method of regular operation of the motor should be taken into account in its design.

Thus a motor may be specified of a certain kilowatt capacity to be operated within given limits—the kilowatt capacity being the rate of input which the motor could take constantly with a given maximum temperature difference above the surrounding atmosphere with the motor designed for constant uniform work. The following relation would practically govern the operation on frequent intermittent work:

K = Kilowatt capacity.

t = Percentage of time motor is worked on any current I.

E = Voltage (practically constant).

$K \times 100{,}000 = \Sigma\, EIt$.

For example, a motor for heavy traction service might be designated a 30-kw. motor, to be operated in service on a line voltage of 500 within the limits of 100 amps. and 250 amps. The commutation limit of the motor would be about five times the standard rating, or

$$5 \times 30 \times \frac{1000}{500} = 300 \text{ amps.}$$

which, in the case assumed, would not be reached in operation, the limits indicating that the capacity of the motor is governed by heating.

This motor on intermittent service ought to operate anywhere within the following conditions:

$$\text{On 100 amps.,} \frac{6000}{100} = 60\% \text{ of the time;}$$

$$\text{On 250 amps.,} \frac{6000}{250} = 24\% \text{ of the time;}$$

or on any products of amperes and percentage of time within these limits integrating 6000, it being, of course, assumed that running on resistance is at all times reduced to a minimum

With such a standardization of motor rating, many advantages would become apparent to those seeking motors for specific service, amongst which may be noted:

(1). The rating of the motor is directly proportional to the average input.

(2). The sum of the operating motor capacities on cars would equal the load on the station, due allowance for outside losses being made

(3). The relation between this method of rating and that at present in use is simple. Calling kilowatt input equal to horse power at the rim of the wheel, to allow for efficiency, then approximately horse power (present rating) $= \frac{10}{3}$ kilowatts (proposed rating).

DR. HUTCHINSON'S COMMUNICATION

The "Electrical World and Engineer," having editorially criticised Mr. Lundie's paper on several grounds, Dr. Cary T. Hutchinson addressed the following letter to the editors, further explaining and indorsing Mr. Lundie's plan:

Mr. Lundie's suggestion is to rate motors intended for intermittent service, such as railway service, on a basis of the average electrical input regardless of the method in which the load varies, assuming always that the variation of load is so made that the temperature attains a constant value; that is to say, assuming that the motor is not allowed to cool down between applications of the load.

This suggestion has for its justification the fact, which seems to be borne out by an examination of a number of test records of railway motors of different sizes and makes, that the I^2R and core losses of a given motor are a constant percentage of the input at constant potential over a large range of input. If this is the case, it is obvious that there will be the same total energy spent in heating the motor whether a certain current is applied all the time or double the current for half the time. Your editorial assumes that the energy losses are constant in amount and not in percentage.

This suggestion to rate a motor on its average input obviously coincides with the present method of rating for continuous duty, since the rated load and the average load then coincide. Equally clearly it does not take into consideration the limitation fixed by commutation. This is a matter which must be considered separately. The present practice in rating railway motors is to specify a temperature elevation of 75 degs. C. for a continuous run of one hour. The rules of the American Institute of Electrical Engineers specify a temperature rise of 50 degs. C. for an intermediate period, the wording of the rule being as follows: "In apparatus intended for intermittent service, as railway motors, starting rheostats, etc., the rise of temperature should be measured after a shorter time, depending upon the nature of the service, and should be specified." That is to say, this rule does not give any definite rating for motors for intermittent service. The question of the time was purposely left open since the conditions of service were so different that it was impossible to specify times in the different cases. You will see that as far as the suggestion to rate on an average load is applicable, the question of time is entirely eliminated, and the rating very much simplified.

Whether the sum of I^2R and core losses in motors other than railway motors is a sufficiently close approximation to a constant percentage of the input, is a matter that can only be determined after a careful examination of data of tests in each particular case. Probably a better way to put the matter would be that the range within which the sum of these losses is a practically constant percentage, would have to be determined separately for each class of motors. For railway motors it seems to be a fact that the sum is a constant percentage throughout the range of practical operation of the motors. It is not constant at very low loads or at very high loads, but this is a matter of no special consequence, since the motors are not expected to operate at either extreme.

This suggestion does not take into account the temperature of the field coils and armature of the motor separately. The temperature elevation is supposed to be measured by resistance, and is the average of the two. To guard the matter carefully, a clause should be added limiting the maximum temperature elevation in either part. The field and armature should be so designed that the temperature elevations of the two parts shall be the same for the load rated in accordance with this method, and the two elements should be separately designed so that neither will attain a dangerous temperature within the range of load permitted to the motor. It is clear that when the temperature of the two parts is not equal, one must be higher than the average, and the other lower.

Motors rated in this manner are rated on a basis of continuous duty with a given temperature elevation. Railway motors, and all motors intended for intermittent service, work on loads which are heavy overloads as compared with their load for continuous duty. Hence, the figure giving the rating of a railway motor in accord-

ance with this suggestion, expressed in kilowatts, would be very low; a 100-h.p. motor would become approximately 30-kw. This would probably not be acceptable to the maker. To avoid this difficulty the motor might be given an arbitrary designation expressing the product of the current and the percentage of time for which the current could be applied. In the case cited by Mr. Lundie, the motor might be called A-B 6000, meaning that it would take 100 amps. for 60 per cent of the time, 250 amps. for 24 per cent of the time, or any intermediate values of which the product is 6000; the limits between which the sum of the two losses is a constant, in this case being 100 and 250 amps.

This matter, I think, is deserving of consideration, as it seems to offer a more satisfactory method of rating motors for intermittent work than any I know of.

MR. LUNDIE'S SECOND COMMUNICATION

Mr. Lundie has also addressed the following letter to the editors of the "Electrical World and Engineer," still further explaining his position:

Your editorially expressed objections to the proposed method of motor rating are essentially that the following two assumptions cannot be true: First, that the electrical efficiency of the motor should be constant at all loads within the commutation limit; second, that the temperature should be the same whether an excessive load were applied at the beginning or at the end of a cycle of test. You sum up by stating that while the advantages of the proposal are not to be gainsaid, yet the uncertainty of the fundamental assumption is too great to warrant its adoption.

No precise criticism can be made of your objections, as they are based on your statement (which is correct) that the assumption is not strictly true. As, however, the proposition is to secure a method of rating which within service limits will represent the capacity of the motor, your objections may be met as follows:

As to your first objection, you support it by stating that the combined copper and iron losses cannot be constant because the copper losses are approximately proportional to the square of the input, while the iron losses, although very complex, are roughly constant, and the sum of a constant and a square function cannot be a first-power function.

Replying to this objection, the *percentage* copper losses are proportional to the square of the input divided by the input, or are directly proportional to the input—a first-power function. If the iron losses were considered constant, the percentage losses would be inversely proportional to the input—a hyperbolic function, but approximately a first-power function on the branch of the hyperbola. The iron losses, however, are not constant in a series motor, and are such as to make the approximation of the percentage losses still closer to a straight line function than if they were constant. In the characteristics of a motor before the writer, the iron losses are approximately proportional to the square root of the input, and the percentage losses, consequently, inversely proportional to the square root of the input. The sum of the percentage copper and iron losses in this motor throughout a range of from 40 to 200 amps., does not vary 2 per cent. Surely this is close enough to a first-power function to satisfy almost the laboratory, not to mention the demands of railway service.

The ideal to be worked towards in motors intended for intermittent, fluctuating work should be that of practically constant electrical efficiency throughout the whole range of service operation.

Your second objection as to the final temperature depending on whether overload were impressed in the beginning or end of a test cycle, will not hold in frequent intermittent service, as we are not dealing with one cycle, but with a continued repetition of cycles in rapid succession, and the maintaining of a given maximum temperature is simply a question of the rate of radiation of heat. With a given average rate of generation of heat, and the same rate of radiation, the temperature remains a constant. The short time between applications of load in railway work does not permit of an appreciable drop in temperature, and the rate of radiation is a function of this temperature.

As to your suggestion that the testing of a motor would be a lengthy and elaborate process, this again is a result of your considering only a single cycle of test. As a matter of fact, the motor in service is under continuous test, the average rate of input as the load fluctuates anywhere within the range of operation, being a measure of the capacity under which it is being operated. This fact is one of the strongest arguments in favor of the proposed method of rating.

The writer is well aware that there are many points which will have an important bearing on the method of rating proposed, such as restrictions to free radiation, unequal heating of field and armature, etc., but believes that they may all properly be made subservient to the general proposition.

Recent Shipments to Havana

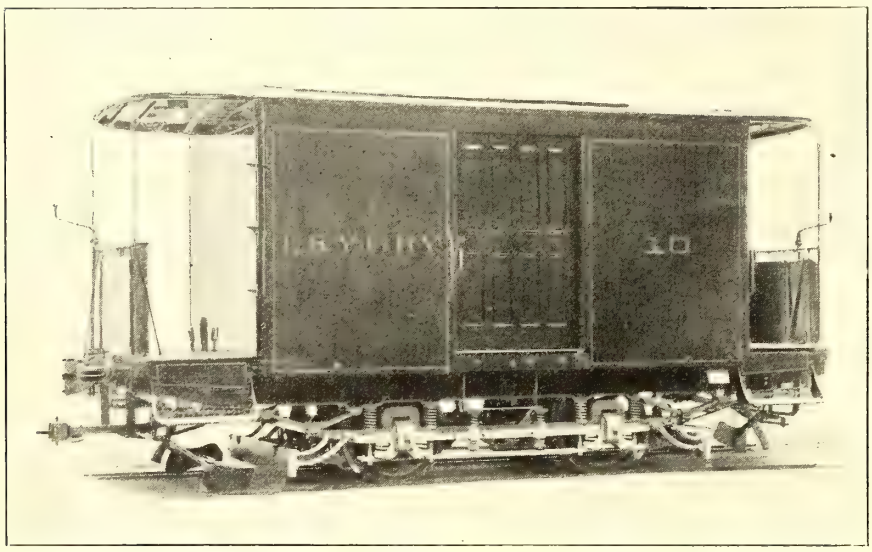
The Morris Electric Company, which received recently, orders for a large amount of railway apparatus for the new electric street railway system of Havana, has already made a number of shipments. On Nov. 27, fifty car loads of Mason terra cotta ducts were shipped from Philadelphia on the Earn Line steamer "Hindoostan." Other shipments which will follow soon are 2200 iron poles, made by the Electric Railway Equipment Company, of Cincinnati, Ohio, 54 miles of overhead line material made by A. & J. M. Anderson; 54 miles of trolley wire from the Waclark Wire Works, a lot of galvanized iron span wire from Washburn & Moen, two trolley wagons made by J. A. McCardell & Company, and thirty car loads of 1,000,000 c.m. feeder cable, made by W. R. Brixey, making altogether 182 car loads, besides the terra cotta shipment.

The Morris Electric Company is also doing a large business with other companies, both in this country and abroad. Among its shipments outside of this country during the past month have been 30 miles of trolley wire, two Trenton trolley wagons, hydraulic rail benders and track tools to Lisbon, a large shipment of miscellaneous equipment to Cape Town, and 280,000 lbs. of copper wire with all necessary brackets and fittings for the new extension for the Mexico Street Railway.

Among his domestic orders, Mr. Morris includes orders for bonds for Elmira, N. Y.; Akron, Ohio; Anderson, Ind.; New York, New Haven & Hartford Railway, Euclaire, Wis.; Detroit, Mich.; Union Railroad, New York, and elsewhere. To facilitate his city work, Mr. Morris has fitted up a shop at Twenty-seventh Street and Ninth Avenue, which contains a brass foundry and full line of machine tools, and will be designed for the manufacture of bonds and general railroad supplies.

Soap for Car Cleaning

A pamphlet containing the papers and discussion at the thirteenth annual convention of the Master Car and Locomotive Painters' Association of the United States and Canada, held at Philadelphia, Sept. 12, 1889, on the subject of the cleaning of passenger cars and locomotives, has recently been published by the Modoc Soap Company, of Cincinnati, Ohio. The discussion on this subject is quite remarkable in showing the universal indorsement by the delegates present of Modoc soap and Modoc car cleaner and the methods employed by them in its use will be of interest to street railway superintendents. The first paper was by T. J. Rodabaugh, master car painter of the Pittsburgh, Ft. Wayne & Chicago Railroad. He stated that he had found that washing cars every day with a window-brush and cold water killed the luster of the varnish and produced in a few weeks a dull, flat looking car. He now employs Modoc liquid for the inside and outside of the cars every thirty days; between these times the cars are wiped off every trip with cotton waste. Every five months Modoc powdered soap is used. Thos. Byrne, master car painter of the Chesapeake & Ohio Railroad, and H. M. Butts, of the New York Central & Hudson River Railroad, gave similar testimony to the value of this soap and cleaner in papers on the same subject. In the discussion which followed various delegates described their methods of cleaning cars, and the discussion elicited the fact that practically all present were users of these products, and that the method of their employment was practically the general directions issued by the Modoc Soap Company. On some roads where there were many tunnels or other conditions which required more frequent cleaning of the cars the latter were cleaned with the liquid more often than on other roads, but the general method of cleaning was practically the same in all.



The Modoc car cleaner is used for ordinary cleaning, and is usually sufficient. In cases, however, where it has not been used regularly and the car has been neglected, a preliminary cleansing with Modoc soap is recommended. This is a mild soap, designed to do the least possible harm to the car. The manufacturers claim that for steam railroad service the cars should be cleaned not less frequently than once every thirty days, and that the cost of treatment is not more than $1.25. It is not economical to allow cars to run five or six months without cleaning.

The Federal Steel Company has just closed a contract with the Corporation Tramways of Glasgow for $500,000 worth of steel rails, special work, etc., for the new electrical equipment. The girder rails will be manufactured at the Lorain Steel Company's shops and the special work at the Johnstown plant.

Heavy Freight Car

The Lewiston & Youngstown Frontier Railway Company, of Lewiston, N. Y., has purchased from the J. G. Brill Company a freight car which is also an electric locomotive and is of rather unusual design. It is represented in the accompanying illustration. The body is 14 ft. long and has the usual sliding side doors, but is otherwise completely enclosed. The width at the sills is 7 ft. 8 ins., and the height inside is 6 ft. 8 ins. There are two platforms, one at each end, fitted up with controllers, brake handles, bells, etc. The construction is unusually heavy for the reason that the locomotive not only has to carry a load of 6 tons, but is also intended to haul standard freight cars. For this reason it is fitted with Master Car Builders standard couplers in addition to the radial draw bar for street railway cars. There are two G. E. 1200 motors. The car is mounted on No. 21-E trucks with a 6-ft. wheel base and 33-in. wheels.

Each platform is fitted with a sand box and Littell track scrapers. In the engraving these track scrapers are shown dropped in position on the left hand end and raised at the opposite end. The car weighed with two motors 18,250 lbs., all of which was, of course, available for adhesion. While the spring arrangement of the No. 21-E truck will make it light and easy riding, the great weight gives it sufficient tractive power to enable it to handle very considerable loads in ordinary steam freight cars.

FREIGHT CAR AND LOCOMOTIVE, LEWISTON

Porcelain Insulators for High-Tension Work

The accompanying engraving shows four new types of porcelain and glass insulators for high-tension work, manufactured by Fred. M. Locke, of Victor, N. Y. Mr. Locke has devoted a great deal of attention to this subject, and his insulators are used extensively on high-tension lines in this country. Fig. 1 shows a porcelain outer shell and glass center insulator manufactured for 50,000-volt lines and tested up to 100,000 volts at the works at Victor. Fig. 2 shows a glass triple petticoated insulator for 20,000-volt lines. Fig. 3 shows a glass insulator for use in transposing telephone lines, and Fig. 4, a similar insulator made of porcelain.

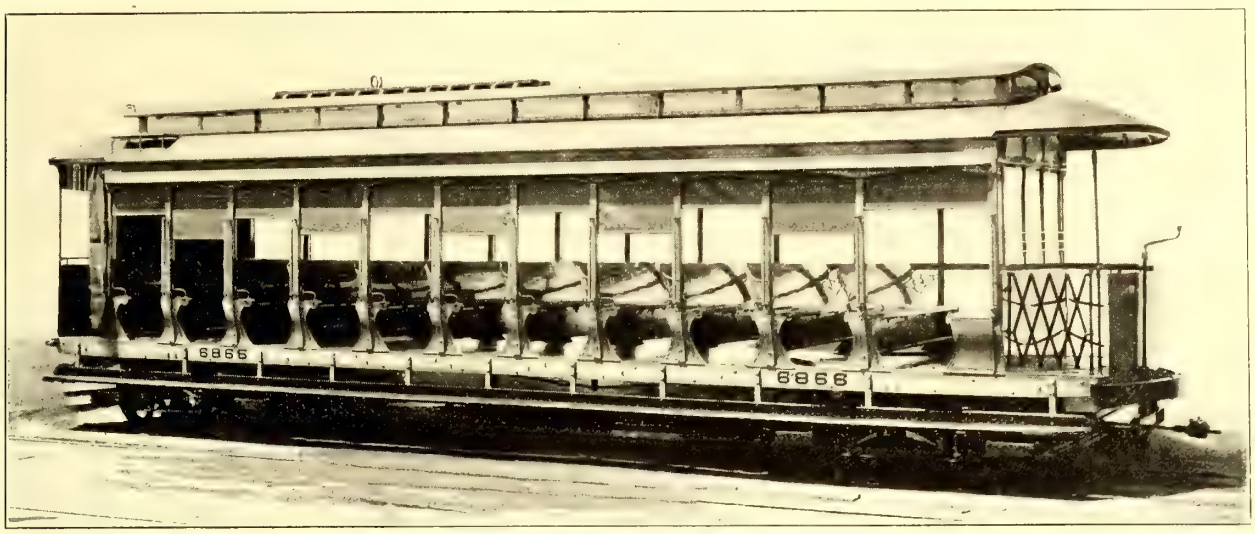
The demands for high-tension insulators have grown so rapidly as to compel the erection of new works at Victor by Mr. Locke. They contain the latest appliances used in the manufacture of insulators, and are two stories in height. The first floor contains the separating and mixing vats and molding process, where the water is squeezed out of the clay; also a great kiln for firing the insulators. The second floor is used for molding, shaping and drying. The insulators are burned at a very high temperature, and are vitrified throughout, increasing both their electrical and mechanical strength. The factory has a capacity of 60,000 insulators a week.

FIG. 2

FIG. 1

FIG. 3

FIG. 4



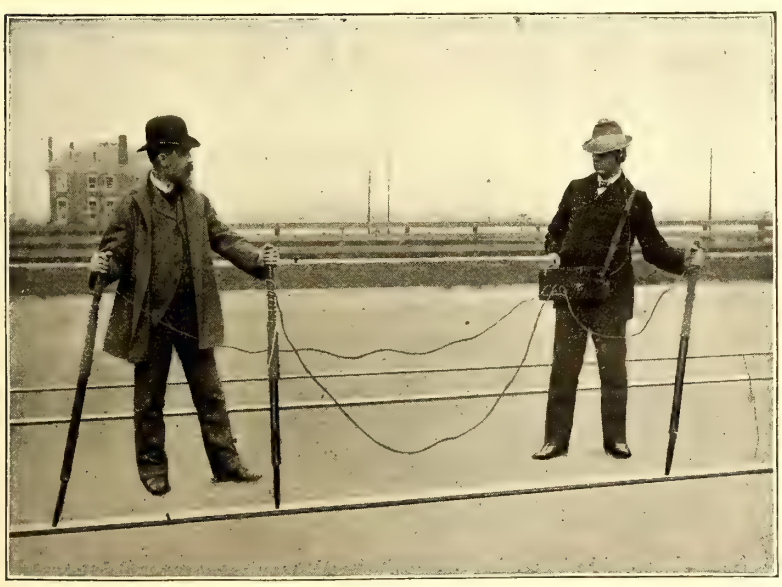
Consolidation of Pennsylvania Roads

All the street railway companies operating in and around Allentown have been merged into one company known as the Lehigh Valley Traction Company. As heretofore constituted, the system in and about Allentown consisted of nine companies, namely: Allentown Passenger Railway Company, Catasauqua & Northern Street Railway Company, Bethlehem & Allentown Street Railway Company, Bethlehem & South Bethlehem Street Railway Company, South Bethlehem & Hellertown Street Railway Company, Allentown & Emaus Street Railway Company, Lehigh Valley Traction Company, Allentown & Lehigh Valley Traction Company, and the Allentown & Bethlehem Rapid Transit Company. The lines of all these companies were operated on lease by the Allentown & Bethlehem Rapid Transit Company, and later by the Allentown & Lehigh Valley Traction Company as lessee. The consolidation has been brought about by each of the seven street railway companies ratifying the agreement of their directors by which the six street railway companies first mentioned are consolidated with and merged into the Lehigh Valley Traction Company, and by a transfer by the Allentown & Bethlehem Rapid Transit Company and the Allentown & Lehigh Valley Traction Company of all their power plants, cars, equipments and assets to the new company, the Lehigh Valley Traction Company. The officers of the new company will be Albert L. Johnson, president; Tom L. Johnson, vice-president, and J. E. Kenney, secretary. The directors are Albert L. Johnson, Tom L. Johnson, Samuel Harris, R. E. Wright and W. J. Hartzell.

Long Open Car for Atlantic City

The West Jersey & Seashore Railway Company, of Atlantic City, has just put in service a number of open cars, whose construction has been modified to suit the requirements of its service.

These cars form a very good example of what is now becoming very popular for street railway men, that is, the specializing of standard types to meet purely local conditions, thus obtaining all the advantages of standard cars, while adopting such features as make them peculiarly well fitted for the work which they are to perform. These cars have four 1-in. truss-rods, secured to the



NEW OPEN CAR FOR ATLANTIC CITY

The cars are intended to run in one direction only around a loop, and have therefore been designed with strict regard to this service by the J. G. Brill Company, which built them. The body is within a fraction of an inch of 38 ft. in length, and is 43 ft. 9 ins. over the dashers. It is 7 ft. wide at the sills and 7ft. 8 ½ ins. wide over the posts. The platforms are short, that in the rear being 3 ft. 3 ins. and that forward 3 ft. 6 ins. These platforms are not intended for passengers. They have no seats, and that in front is closed on one side by the guard-rail, which runs from dasher to dasher, and is screwed fast, and on the other side by a Brill folding gate. The trolley board is placed at the rear end of the car, its center being 10 ft. 6 ins. from the rear end. As the car is to be operated in one direction, only one bulkhead is used, which is at the forward end. There is but one step, 11 ins. wide, having a 16½-in. riser. It is 20 ins. from the head of the rail.

The car is mounted on a pair of No. 27-G. trucks. There are two Westinghouse No. 38-B motors on the inside of the rear axles, with nose suspension. The forward axle is arranged for a Westinghouse compressor.

The inside of the car is finished in cherry and ash. The seats are reversible except the one against the bulkhead. The panels are of the round-corner, seat-end type. A rather unusual feature is the covering of the roof with tin instead of canvas. There is one gong, one sand-box and a pilot on the front end of the forward truck.

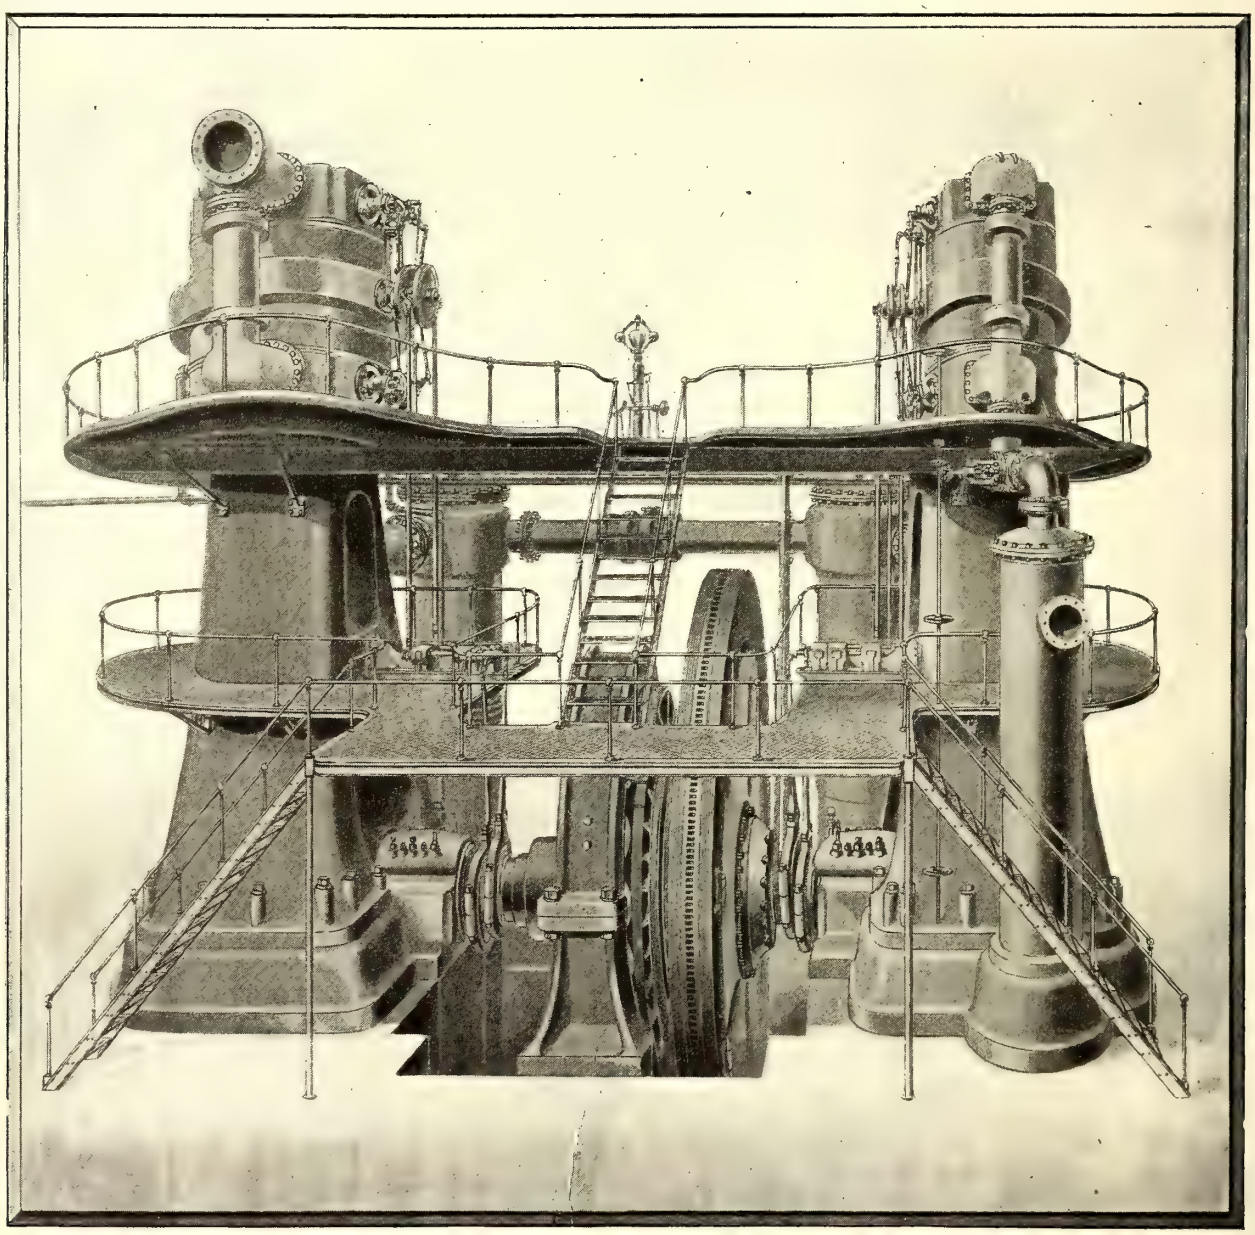
insides of sills below the bolster. This is necessary, as the weight of the car without motors is 20,700 lbs. The trucks weigh 5000 lbs. each.

TESTING RAIL BONDS IN BOSTON

A New Method of Testing Rail-Joints

A new method of testing the resistances of rail-bond has been invented by R. W. Conant, electrical engineer of the Boston Elevated Railway Company, and is in use on the lines of that corporation. A great advantage of the device is its quickness, as well as its accuracy, and its ability to make measurements rapidly enables the company to make frequent tests of its rail-bonds, an advantage which is self-evident.

The accompanying engraving shows the method of its practical application. The joint being tested is between the left-hand and center poles, and the inspectors are determining the resistance introduced into the rail circuit by reason of this joint. The method employed is the simple one of balancing the resistance of two circuits against each other and of determining when they and the other resistances are equal by telephonic means. The two circuits used are that between the center pole and the left-hand pole and that between the center pole and the right-hand pole. If there was no joint it would be necessary, of course, in order to make the circuits of equal resistance, to have the center pole midway between the two outside poles. If, however, the joint adds a resistance to a 30-ft. rail equal to, say 3 ft. of track, the center pole will have to be 3 ft. nearer the left-hand pole when these two span a joint. This joint represents a fairly good condition of track. With poor joints, however, the right-hand, or indicating pole, would have to be shifted anywhere from 6 to 30 ft. away from the center pole, depending on the condition of the joint, while with bad joints it would be over 30 ft.



As will be seen, the Conant rail-joint testing instrument utilizes the current already on the track by reason of the car service, and no matter how variable this current may be, since the variation through the joint and adjacent rail is precisely the same, it introduces no error. The operator, having the case slung over his shoulder, directs his assistant to strike his two connecting poles into the rails, spanning the joint, with about 3 ft. between the poles. He then strikes his indicating pole into the rail, say 4 ft. from the center pole, and listening at the telephone attached to the box, which has a continuous interrupter in circuit, he throws a switch alternately to right and left and compares the two sounds heard from joint and 4 ft. of rail. Finding in the above case that the sound from the joint is the louder, he shifts his pole so as to span a greater length of rail. When the sounds are found to be approximately equal, a final test of balance is made by leaving the switch on the box in the middle position, when no sound should

be heard. In case a slight sound is noticeable he shifts his pole until it is entirely killed. This then gives the length of rail equivalent to the joint, from which, if it is desired, knowing the weight of the rail, the resistance may be calculated.

An intensifying attachment on the instrument allows of its use with very weak track currents, and the complete instrument is a simple and durable piece of apparatus. The instrument is being placed on the market by the Chase-Shawmut Company, of Boston, Mass.

Large Corliss Engine

The largest direct-current generating unit in the world is now approaching completion at the works of the International Power Company, at Providence, R. I., and will be installed in the power station of the Boston Elevated Railway Company. The indicated horse power of the engine at maximum efficiency is 4000 h.p., but this load can be varied 12 per cent to 15 per cent either way without materially effecting the efficiency. The engine, which is illustrated herewith, is of the vertical type, compound condensing, with cylinder dimensions 42 ins. and 90 ins. by 60 ins. stroke, and will run at 75 r.p.m. under a steam pressure of 180 lbs. The valves are of the Corliss type, but are located in the heads, instead of on the sides, of the cylinder, the usual practice. In this way, the clearance is reduced to a minimum, that in the low-pressure cylinder being less than 2 per cent. The cylinders are jacketed, barrel and head.

4000-H.P. CORLISS ENGINE FOR BOSTON ELEVATED RAILWAY

The pistons are of the box type. The rods are 9 ins. in diameter, have a 3-in. hole throughout their length, and are of nickel steel of 50,000 lbs. elastic limit. They are hydraulic forged and oil tempered, and are packed with Tripp metallic packing; below the metallic packing box is another of soft packing to prevent the passage of oil. The cross-heads are of air furnace charcoal gun iron. The connecting rods are all hydraulic forged nickel steel. They are circular in section, 9½ ins. in diameter near the cross-head and 13 ins. near the crank-pin. A 3½-in. hole extends through the rods from end to end. The distance between pin centers is 13 ft. 9 ins. The cross-head pin and crank-pin are all open-hearth forged nickel steel, bored out and oil tempered.

The engine shaft, which is furnished by the Bethlehem Steel Company, and illustrated in the Street Railway Journal for August, is of hollow forged nickel steel 27 ft. 10 ins. in length, 32 ins. in diameter in the bearings, and 37 ins. in the body, with a 17½-in. hole through its length. The weight of the engine shaft is 65,410 lbs., of the crank disc 58,004 lbs., of the armature 125,000 lbs., and of the fly-wheel 265,515 lbs., making a load on the bearings aside from the connecting rod, pistons, etc., 513,929 lbs.; 143 lbs. per square inch of projected area.

The fly-wheel is 28 ft. in diameter; the main bearings are 32 ft. in diameter, 56 ins. long and 19 ft. 9 ins. center to center. Both top and bottom shells are water jacketed, and oil is fed to the bearings at both top and bottom.

The cylinders are set 29-ft. 2-in. centers, with crank at 90 degs. Steam is brought to the engine by a 16-in. main, which enters first a receiver 3 ft. in diameter; from the receiver it passes through a 12-in. globe throttle valve to a 12-in. pipe, which conducts it to the steam valve chambers of the high-pressure cylinder. The valve gear is so arranged that the governor may control the cut-off in both cylinders, or the low-pressure cylinder may be run

on the fixed cut-off. The change can be made while the engine is in motion. The engine is guaranteed to regulate as to speed within 1 per cent under practically constant load, and to vary not more than 3 per cent with sudden changes of 25 per cent in load.

New Long Car for Cleveland

A type of car which is proving very satisfactory for long distance riding on the Cleveland City Railway is illustrated in this

LONG DOUBLE-TRUCK CAR FOR CLEVELAND

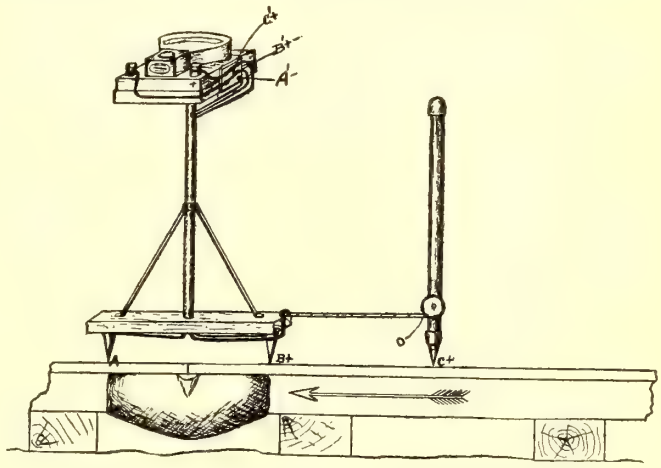
connection. It is used on the St. Clair, Detroit & Rocky River Line, which is controlled by the Cleveland City Railway Company.

The car, which was built by the G. C. Kuhlman Company, has a length over all of 47 ft., and contains fifteen benches, each capable of seating six passengers, or a total of ninety passengers in all. The width over the posts is 8 ft. 4 ins., and that over the steel sill plates 7 ft. 9 ins.

The car is finished in white oak, with cherry trimmings, and bird's-eye maple ceilings. The metal trimmings are of polished bronze. The car is vestibuled in front, and is equipped with four 35-h.p. Westinghouse motors on Brill No. 27 trucks.

This car has been adopted as the standard for this class of service on the Cleveland City Railway, and the Kuhlman Company is now engaged in building twenty similar in general character to that illustrated.

Track Scrapers



There is one piece of apparatus of the greatest value to street railway companies which receives little attention—this is the track scraper. In summer and winter, and on almost all lines except those running on the cleanest city streets the track scraper can be applied to advantage. In the winter time it performs invaluable service, and cars during early hours of snow storms can keep up to the schedule until the snow plow or sweeper is put at work. In the summer time mud and dirt on the rails can be removed and not only a better contact, but much easier riding, can thereby be obtained.

One of the best known devices of this kind is the Littell track scraper, as built by the J. G. Brill Company. Its action is automatic and its construction is of the simplest character. A heavy bar is bent into a rectangular U-shape. This is fastened to a board by a pair of bearings. At the outer ends of the bar the two scrapers are attached and at the bottom of the U, a lever leading to the platform is attached. The normal position of the scraper is up or raised from the track and the treadle hooked to the platform in a position where a touch of the foot will drop the scrapers upon the track. It is always ready for service at a moment's notice, a touch of the toe being all that is necessary to drop the blades upon the rails. The application is practically instantaneous, the blades may be dropped, the obstruction removed and the scraper lifted by a downward motion of the foot. This form of scraper has repeatedly been used as a life saving device, the blades being dropped the instant a person was discovered on the track. When lifted the blades are entirely out of the way and not liable to be interfered with. The whole arrangement is very light and strong and can be readily applied to any car by simply bolting the plank upon which it is mounted to the platform timbers. A view of the device is shown in the engraving of the Lewiston &

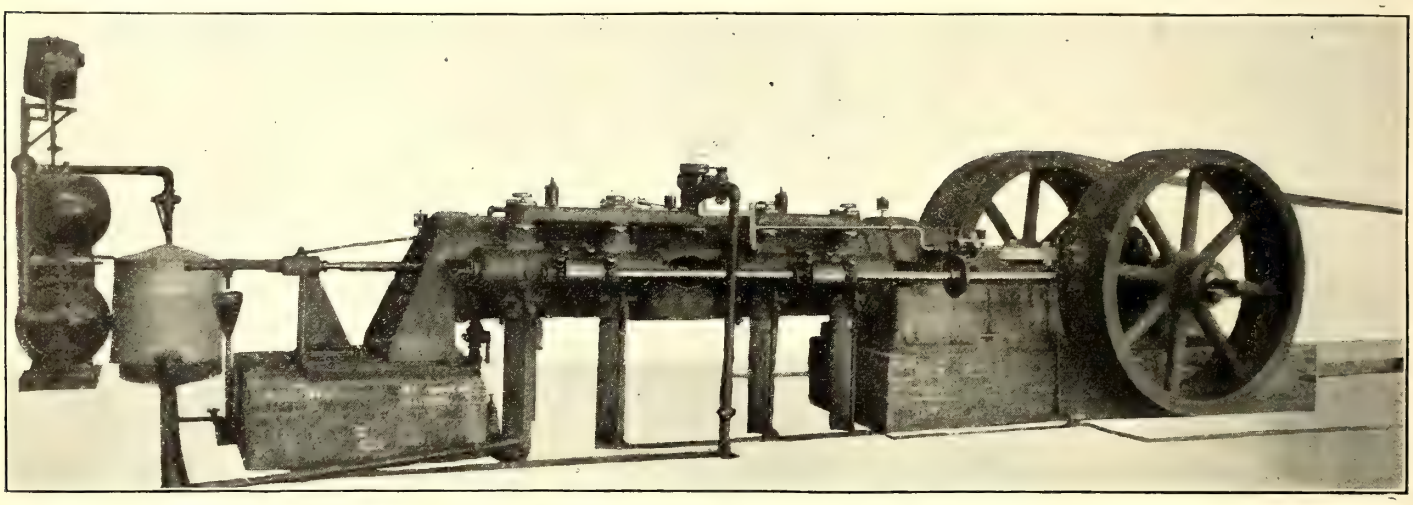
Device for Testing Rail Bond Resistances

The accompanying sketch shows an instrument for determining the resistances of rail-joints, invented by Chas. J. Schnaus, of the Missouri Railroad Company, of St. Louis, Mo. As shown, it is applied to a cast-welded joint, but readings can be made of any type of bonded joint.

The apparatus consists of a voltmeter, reading tenths of volts, mounted on a stand made of pipe, and with a wooden base. The latter is fitted with two hardened steel points, *A* and *B*, which serve as contacts, and are connected by wires passing through the rod to two points, *A'* and *B'*, on the two-circuit switch, attached to the voltmeter. The apparatus is also furnished with a third rod, *C*, which has a hardened steel point at its base, and is connected to the base of the stand by a steel tape line. The tape reel, which

DEVICE FOR TESTING RAIL BOND RESISTANCES

winds up automatically, is attached to the rod *C*, and the outer end, which is attached to the stand, is connected electrically to the voltmeter at the joint *C'*. The points *A* and *B* on the stand are spaced so that they just bridge the joint, if the track is cast welded, or if a fixed distance, say 30 ins. apart for an angle-plate joint. Readings are taken during the day while the regular schedule is in force.



The instrument is first placed over a joint and the drop in voltage between *A* and *B* is taken on the voltmeter. The rod *C* is then drawn away from the stand until the resistance between *B* and *C*, as determined by the voltmeter reading, is the same as that between *A* and *B*. This distance is then read from the tape, and the difference between the length *A B* and *B C* represents the resistance of the joint in terms of inches of rail length. For convenience in reading this distance the zero point of the tape can be set at 30 ins. from *B*, or the distance between *A* and *B*. The re-

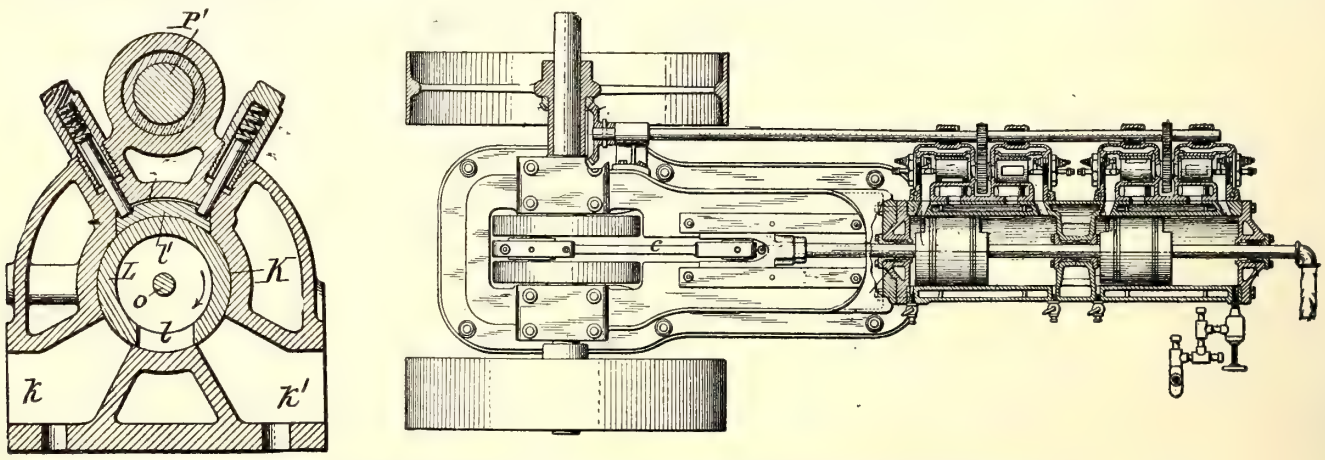
sistance in fractions of an ohm can easily be obtained from this measurement if desired.

The advantages claimed for this instrument are, that it is portable, does not interfere with the running of the cars, requires only the ordinary contact with a rail, is easily manipulated and fairly rapid. Experience with this instrument in St. Louis shows that two men can measure 2 miles of double track laid with 30-ft. rails in a day.

The Standard Automatic Gas Engine

The use of gas engines for power station service presents many advantages, and it is claimed that in some cases they are more economical than steam power, especially in space, first cost, attendance and fuel. A new engine of this type is that built by the Standard Automatic Gas Engine Company, of Oil City, Pa. While the company is comparatively unknown as yet to the majority of present or prospective gas engine users, and while many of the details of the engine as described below are radically novel, the fact that neither the company nor the engine is in inexperienced hands is proven by mentioning the name of the president of the one and the designer of the other, J. W. Raymond, designer of the improved Raymond engine, built for many years by the J. I. Case Threshing Machine Company.

THE STANDARD AUTOMATIC GAS ENGINE



The engine operates upon the familiar Beau de Rochas, or four-stroke cycle, commonly known as the Otto, giving per single-ended cylinder one impulse during two revolutions. The special features deserving, perhaps, first mention, are the valve and valve gear. There is only one valve for both admission and exhaust, and this valve is a hollow cylinder of cast-iron, chilled and ground. The interior of the valve is open to the engine cylinder and as the valve turns in the valve chest, an opening in the valve alternately connects the cylinder with an admission and an exhaust port. A cross section through this valve is shown in Fig. 1. *L* is the cylindrical valve rotating in the valve chest, *K*, and held up against the valve seat by the springs and piece, *l'*. As it rotates, the port, *l*, connects the interior of the valve—which is open to the cylinder—alternately with the admission chamber, *k*, and the exhaust chamber, *k'*. The valve does not oscillate or have a reciprocating motion of any kind, but simply rolls continuously around in one direction, being turned by a horizontal shaft, driven by mitre gears from the main shaft, and turning the valve stem by 2 to 1 spur gears. The absence of poppet valves, cams, springs, and so forth, makes the engine remarkably noiseless.

The ignition is electrical in character, accomplished by a wiping spark between side tool-steel electrodes. The moving contact simply rotates with the valve, and the stationary contact is held by springs outside the valve chest and adjustable while the engine is in operation.

The governing of this engine is not accomplished by missing impulses, but by varying the quantity of the charge by throttling. The mixture is throttled by one plain balanced butterfly valve as simple as the damper in a stove pipe and almost entirely free from friction, since all points of the butterfly, except the stem, are out of contact with the walls of the valve chamber except when the valve is shut tight. For this reason the force which the governor must apply to move the valve is much less than that required for piston or other forms of valves, the leverage and necessary extent of motion of the fly balls is reduced and the regulation is correspondingly perfect. The proportions of the mixture are determined by entirely independent valves in the incoming air and gas pipes, the constituents being pulled through these and the mixture being pulled through the governing valve by the suction of the filling stroke.

The engine is horizontal and, in small sizes, 15 h.p. and upward, is of the ordinary single-acting form, with a trunk piston acting as a cross-head. In sizes of 50 h.p. and up, the engine is made with two single-acting cylinders tandem on the same piston rod. The cycles of the two cylinders are displaced one revolution from each other, so that one impulse per revolution is obtained, the expansion stroke in one cylinder occurring immediately before the compression stroke in the other.

Naturally, some means must be devised for cooling the piston rod, which runs out through the explosion chamber of the cylinder nearer the crank to the piston of the other cylinder. The piston rod is extended out through the head of this cylinder also, in the form of a tail rod, and is made hollow. A long pipe is then in-

FIGS. 1 AND 2.—CROSS SECTION THROUGH VALVE AND HORIZONTAL SECTION AND PLAN OF ENGINE

serted into the hollow rod and is packed at the tail rod end. Cooling water is injected through this long pipe clear into the rod in the second cylinder and flows back inside the rod, but outside the pipe, to a drip at the tail rod end. The piston rod is packed with non-inflammable packing where it comes through the cylinder head.

The company has recently completed a still more interesting engine with two 18-in. x 18-in. double-acting cylinders, tandem on one piston rod, with outside cross-head of standard steam engine construction. The two double-acting cylinders give two forward impulses per revolution simultaneous with the compression strokes in the other end of the cylinders. The heavy compression both ways gives very smooth running, even with considerable slack in the cross-head and crank-pin boxes. The piston rod of this engine, owing to the heavy strains it is called upon to bear, is made of nickel steel, drawn with the hole for the cooling water in it. The water in this case is introduced through the cross-head and discharged through the tail rod. One balanced-pressure sight-feed lubricator on the center of each cylinder lubricates the pistons with a high fire-test engine oil. Fig. 2 shows a plan of this engine.

The pistons are cored out and the water passing through the rod is compelled to circulate also inside the pistons, thus cooling them. One horizontal shaft runs along beside the cylinders and turns the four valves of this engine (one for each end of each cylinder) through two pairs of cut gears. The governor actuates one butterfly valve, which throttles the mixture to all four cylinder ends. The course of the mixture to any one, two or three of the four cylinder ends may be cut off to increase the compression and economy at low loads. Indeed, any valve chest may be opened and the igniter taken out while the engine is running.

This engine is started by turning it over to the proper point and igniting electrically a charge of very slow burning powder in an enclosure connected with one cylinder head. The connection is made through a number of right-angle bends made in capped tees in such a way that the ash from the powder blows past the bends and is caught in the caps, from which it may be removed from time to time. The engine may also be piped to a compressed air tank or steam supply for starting.

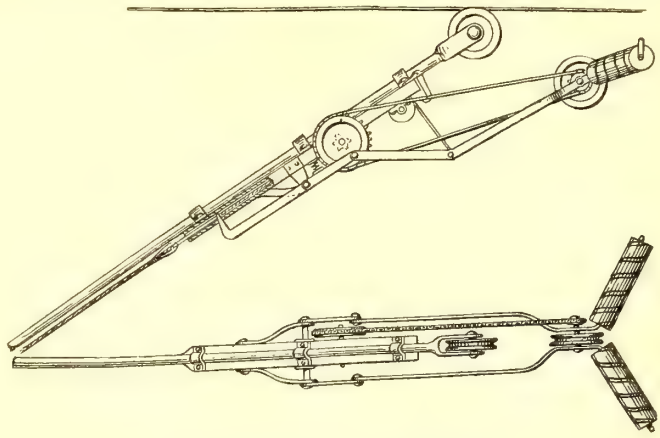
This engine is shown on page 896, set up and belted to a 150-kw. Westinghouse generator for the Oil City Street Railway. A duplicate is under way for the same purpose, and two 500 h.p. each are under order. No storage batteries will be used.

The engines are rated on the basis of mean effective pressure, the one shown in the illustration being conservatively rated at 200 h.p. on the basis of a mean effective of 32 lbs. per sq. in., although much higher mean effectives may be obtained. Indeed, this engine is guaranteed to develop 300 brake h.p. with a consumption of not more than 3000 cu. ft. of natural gas per hour, this gas showing about 990 B. T. U. per cu. ft.

An interesting equipment of engines for which the company has closed a contract will consist of four like that shown in the illustration, which are ordered for use in Germany. These will be made into two engines by coupling two of them together with cranks at quarters, each complete engine thus consisting of two pairs of tandem double-acting cylinders giving four impulses per revolution. Each such engine will be direct coupled to a three-phase 60-cycle alternator mounted between the cranks, and these alternators will be run in parallel and with rotary converters. Another order is for two engines of 350 h.p. each, to carry a street railway load in Western Pennsylvania. These engines will get their gas from by-product coke ovens, a gas which is at present thrown away, and will require no elaborate preparation, such as washing or scrubbing to adapt it for use in the engines. All it needs is to be passed through holders in which it can deposit its tar.

The Standard Automatic Gas Engine Company, of which Mr. Raymond is president, as noted above, is capitalized at $36,000, but expects to increase its capitalization to $100,000 to accommodate increasing business. It has recently erected new shops on the banks of the Allegheny River, about 2 miles below Oil City. The building contains also the new street railway gas engine power house and is about 180 ft. long by 67 ft. wide. The contract will soon be let to lengthen it 150 ft.

Safety Third-Rail System at New Britain



A series of tests were made Nov. 9, of the McElroy-Grunow safety third-rail system at New Britain, Conn., on a section of track belonging to the New York, New Haven & Hartford Railroad Company. The tests were made under the supervision of William Grunow, Jr., the inventor of the system. Owing to the shortness of the section high speed could not be secured, but the switches showed their ability to handle heavy currents. The brakes on the trial car were tightened, enabling the amount of current taken from the rails to reach as high as 1000 amps. at a pressure of 550 volts, but no sticking or arcing of the contact surfaces was discernible after careful inspection had been made.

The system consists of two rails carried between the regular track rails. One of these is a conductor rail, from which the current is taken into the car; the other is used for transmitting the current controlling the switching devices in the section boxes. The main current is not broken until the car begins to take current from the next following section. In this way there can be no arcing in the section box.

Trolley Pole Replacer

A new and ingenious trolley wire finder has recently been invented by Paul Kaufmann, of Lockport, N. Y., and is illustrated herewith. The frame of device is about 14 ins. long, and is constructed of tubing to render it light. When not in use, it lies from 4 ins. to 5 ins. below the trolley wheel, just low enough to clear the roof of the car when the trolley is running on a low wire. The device is actuated by a spring at the foot of the pole, which spring is connected by a wire to the replacer frame. The connection is not made directly, but through a rack bar shown in the engraving.

The operation of the device is then as follows: When the regular trolley wheel leaves the wire, it carries the replacer up with it until this latter strikes the wire. This actuates the double lever

TROLLEY POLE REPLACER

in the frame of the device, disengaging the rack-bar to which the spring is attached. The spring then draws up the replacer, pulling down the trolley. The grooved deflecting rollers then carry the wire to the auxiliary trolley wheel between them. This auxiliary wheel is connected by a sprocket chain with a gear wheel on the trolley pole, and its revolution turns the latter wheel. This gear wheel engages the rack-bar and retensions the spring until the rack-bar touches a hasp, which holds the frame in replacing or operative position. As the hasp releases its hold, the frame drops down and the regular trolley wheel is guided to the wire. At the same time the bar at the end of the frame engages the rack-bar, and the device assumes its original position.

The engraving does not represent the device in its proper proportions, but the auxiliary apparatus has been enlarged to show it more comprehensively.

Organization of R. W. Blackwell & Co., Ltd.

The announcement was made last month that Robert W. Blackwell & Company, Ltd., of 39 Victoria Street, Westminster, London, S. W., has been registered with a capital of £200,000. The company has been formed for the purpose of taking over the business of engineers and contractors heretofore carried on by Messrs. Robert W. Blackwell & Company, at London, Liverpool, Paris and New York. The directors of the company are: Robert W. Blackwell, Philip Dawson, Benjamin Hunting Howell, Sir Charles E. Howard Vincent and Francis Henry Barker. The change in organization mentioned has been made to extend the business of the company.

R. W. Blackwell & Company is one of the oldest and best established firms engaged in the electrical contracting and supply business in England, and has established a high reputation in the tramway and lighting fields. It has been the contractor for or has furnished supplies to a very large number of the electric tramway enterprises in Europe, particularly in England, and has branch offices in a number of the European capitals and in New York.

Annual and Quarterly Reports of New York City Companies

MANHATTAN RAILWAY COMPANY

At the annual meeting of the stockholders of the Manhattan Railway Company, of New York, held Nov. 8, the following directors were re-elected: George J. Gould, Russell Sage, Samuel Sloan, Edwin Gould, R. M. Gallaway, Marcellus Hartley, Thomas T. Eckert, G. P. Morosini, Donald Mackay, Howard Gould, Warren B. Smith, John T. Terry and Alfred Skitt. The officers were re-elected as follows: President, George J. Gould; vice-president, Alfred Skitt; secretary and treasurer, D. W. McWilliams. The company's report of operation is as follows:

Year ending Sept. 30,	1898	1899
Gross earnings	$9,204,466	$9,325,111
Operating expenses and taxes	6,066,682	6,113,790
Net earnings	$3,137,784	$3,211,321
Interest on bonds	1,889,681	1,889,681
Balance	$1,248,103	$1,321,640
Dividends	1,200,000	1,560,000
Deficit	sur.$48,103	$238,360
Previous surplus	4,353,104	4,401,207
Total surplus	$4,401,207	$4,162,847

Operating expenses, per cent, excluding all taxes, 56.69; operating expenses, per cent, including all taxes, 65.56; number of passengers carried, 177,204,558.

This report, compared with that of 1898, shows an increase in dividends of $360,000, due to the payment of dividends of 2 per cent on $30,000,000 and on $48,000,000, the increased capital arising from the $18,000,000 issue of stock to provide for electrical equipment and to extinguish floating debt and for betterments. The report on passengers carried, 177,204,558, shows a falling off and is attributed to the competition of the surface roads. The figures in 1898 were 179,728,356, in 1897, 183,184,641, and in 1896, 182,437,244.

Of the meeting and the affairs of the company Russell Sage is quoted as saying: "No interest connected with William C. Whitney had a voice at the meeting. I have stated time and again that Mr. Whitney had no investment interest, if any, in Manhattan. Before the election I told Mr. Gould that it would be impolitic, in view of the satisfactory condition of the company and the progress making in changing the motive power to make any change in the directorate or the officers. He concurred in my views. The meeting was entirely harmonious. The subject of electric traction was not brought up formally, but it was discussed between individual stockholders, and full satisfaction was expressed at what has been done and in the plans which are being carried out. No matter what the stock market thinks of our report for the year, we have every reason to be satisfied with the system and its finances."

The annual report of the Manhattan Railway Company, published above, was supplemented during the month by a report for the quarter ending Sept. 30. The figures of this quarter, as compared with that of last year and of 1892, follow:

Quarter ending Sept. 30	1892	1898	1899
Gross receipts	$2,468,730	$1,788,613	$1,912,829
Operating expenses	1,294,251	1,249,003	1,274,019
Net earnings	1,174,479	539,610	638,810
Other income	35,000	47,500	188,300
Total	1,209,479	587,110	827,110
Interest, taxes, etc	681,089	607,172	646,045
Surplus for stock	528,390	def.20,062	181,065
Dividends	a450,000	b300,000	c480,000
To surplus account	78,390	def.320,062	def.298,935

a, 1½ per cent on $30,000,000; b, 1 per cent on $30,000,000; c, 1 per cent on $48,000,000.

QUARTERLY REPORT OF THE METROPOLITAN STREET RAILWAY CO.

The Metropolitan quarterly report for the year ending Sept. 30, is as follows, comparison being made with 1898 and 1897:

Quarter ending Sept. 30	1897d	1898	1899
Gross receipts	$2,407,083	$3,120,371	$3,560,827
Operating expenses	1,289,277	1,548,396	1,716,613
Net earnings	1,117,806	1,571,975	1,844,214
Other income	86,829	97,515	77,853
Total	1,204,635	1,669,489	1,922,066
Fixed charges	820,448	1,117,680	1,130,330
Surplus for stock	384,187	551,809	791,736
Dividends	375,000e	375,000e	787,500f
To surplus account	9,187	176,809	4,236

e, 1¼ per cent on $30,000,000; f, 1¾ per cent on $45,000,000; d, excluding Second Avenue Railroad.

ANNUAL REPORT OF THE THIRD AVENUE RAILROAD COMPANY

At the annual meeting of the stockholders of the Third Avenue Railroad Company, of New York, held Nov. 15, the old board was re-elected except that William H. Webb, recently deceased, was replaced by George A. Heyl. The statement of operation for the year ending Oct. 31, 1899, with which is compared the report for the last two years, is as follows:

	1897	1898	1899
Receipts from passengers	$2,570,842	$2,359,799	$2,098,871
Operating expenses	1,444,648	1,180,465	1,392,400
Earnings from operation	1,126,194	1,179,334	706,471
Income from other sources, including dividends on stock of other companies	47,368	42,316	680,933
Total earnings	1,173,562	1,121,650	1,387,404
Fixed charges			
Interest on bonds	250,000	250,000	250,000
Taxes	122,286	119,578	116,020
Net earnings	801,276	752,072	1,021,384
Dividends	850,000	800,000	840,000
Surplus	def.48,724	def.47,928	$181,384

It will be noticed that gross receipts have fallen off about 11 per cent, and earnings from operation about 35 per cent. As against this there appears income from other sources this year of $680,933, as against but $42,916 last year. In order to make the showing a fair one, account should be taken of the interest on the floating debt incurred in purchasing the stock of the underlying companies, now in the treasury of the Third Avenue Company. In the balance sheet of June 30, 1899, this floating debt amounted to nearly $13,500,000, the interest on which at 4 per cent would amount to about $540,000, or at 5 per cent, $675,000.

The company's dividends in 1894 were 8 per cent, in 1895, 9 per cent; in 1896, 9¾ per cent; in 1897, 8¼ per cent; in 1898, 7¾ per cent, while in 1899, three dividends of 1¾ per cent were paid and the fourth, just declared at the annual meeting, was 1¼ per cent, making 6½ per cent for the calendar year.

The falling off in earnings shown in the annual report is, of course, due in large part, if not entirely, to the delays and difficulties of traffic in the reconstruction period. With the new long cars now in operation and which are likely to become the most popular cars in the city, the Third Avenue Railroad will doubtless gain traffic from both the Manhattan Elevated and Metropolitan Companies, and will even, perhaps, return to the standard of earlier days.

New Franchise in Milwaukee

The Milwaukee Electric Railway & Light Company and the special committee of the Common Council have at last agreed on the terms of the new street railway ordinance. It remains now for the Common Council to act on the agreement. The city agrees in the ordinance to grant the extension of all the company's franchises for a term of about ten years, all to end in 1934, and to grant eleven additional franchises to terminate at the same time. In return for these privileges the company agrees to grant workingmen's four-cent fares from 5:30 to 7 A. M., and from 5 to 6:30 P. M., beginning Jan. 1, next, and at the end of five years to give a straight four-cent fare. In return for these concessions the city will abandon all right to regulate or change fares until the new franchises expire in 1934. No provision is made for the readjustment of fares at any time during the next thirty-five years, no matter what the changed conditions may be. The company has accepted this proposition, and on these terms it has made formal application to the Common Council for the additional franchises agreed upon. The ordinance, as it now stands, is somewhat different in terms from that which the committee agreed on a few days ago.

Instead of demanding a sliding scale reduction in fares, reaching a four-cent fare four years hence, the sliding scale is abandoned and the four-cent fare is to be introduced after five years. The workingmen's fares are to go into effect at once and the council committee abandons its demand that the company pay for all original paving between the tracks.

Electrical Banquet in Philadelphia

The Morris Electric Company, of New York, tendered a banquet to the electrical press and a number of persons in the electrical railway industry on Nov. 14, at the Bingham House. Among those present were: Edward S. King, of the Baltimore & Ohio Railroad; C. B. Fairchild, "Street Railway Review;" George Mason, Potomac Terra Cotta Company, of Washington, D. C.; S. H. Harrington, Harrington Rail Bonding System, of New York; Elmer P. Morris, Morris Electric Company, of New York; John Blair MacAfee, president, Railways Company General and American Engineering Company, of Philadelphia; C. C. Bent, superintendent, Baltimore & Ohio Railroad Company; G. E. Pratt, Hubbard Electric Brake Company, of Chester, Pa.; George F. Porter, W. R. Brixey, New York; D. A. Hegarty, Railways Company General; W. E. Harrington, Camden & Suburban Railroad Company; Ambrose B. Umstead, Earn Line Transportation Company; W. H. Antrome, "Philadelphia Record;" J. Franklin Stevens, Keystone Electrical Equipment Company; Stephen Goddard, "Electrical Review," New York; J. L. B. Haehulen, Baltimore & Ohio Railroad Company; F. B. Franklin, Baltimore & Ohio Railroad Company; W. K. Beard, STREET RAILWAY JOURNAL.

Speeches were made by Mr. Bent, of the Baltimore & Ohio Railroad Company; Mr. MacAfee, and, of course, Mr. Morris. Many of those present, including Mr. Morris, were pioneers in the electric railway field, and their reminscences of the early struggles were of great interest to those who had only lately engaged in the work. Credit was given to the genius of Van Depoele, Sprague, Thomson and other inventors, as well as to the ability of such engineers in developing the work as F. S. Pearson, B. J. Arnold, Louis Duncan, G. F. Greenwood, H. F. Parshall and W. E. Baker. Mr. Morris received many congratulations upon the recent large orders which he had received for the equipment of the Havana Electric Railway, reference to which is made elsewhere in this issue. The dinner was given upon the occasion of the first shipment of fifty car loads of terra cotta ducts by steamer to Havana.

Consolidation of Well Known Publications

In the final issue of "Paper," published Nov. 10, it is announced that after that date "Paper" will be amalgamated with the "Paper Trade Journal." The conditions which brought about the establishment of "Paper" have now been removed through its agency, for the recent change of ownership in the "Paper Trade Journal," by which one of the best known newspaper men in this country, Col. C. H. Jones, became principal owner and manager of this old and well known trade publication, was due, in large part at least, to the rivalry of "Paper" during the past year. Col. Jones deserves, and will receive a large measure of success in his new venture, and the effect of his remarkable ability and enterprise has already become apparent in the pages of the "Paper Trade Journal."

Personal

MR. A. K. BAYLOR, of London, has arrived in America.

MR. HARRY W. HEAP, receiver of the Phœnix City Railway Company, was married recently to Miss Helen Wells, of Prescott.

MR. M. ADAMS, of Montoursville, Pa., assumed the duties of assistant superintendent of the Montoursville Passenger Railway Company on Nov. 1.

MR. HENRY N. RANSOM, purchasing agent of the International Traction Company, of Buffalo, was married Nov. 21, to Miss Alice Gillet.

MR. W. C. HELLER has resigned the general managership of the Montgomery & Chester Electric Railway Company, to accept a similar position on the Rapid Transit Railway of Xenia, Ohio.

MR. THOMAS E. MITTEN, general superintendent of the Milwaukee Electric Railway & Light Company, has been traveling in Canada and the East during the past two weeks.

MR. FRANK E. ROWELL has been elected treasurer of the Portsmouth, Kittery & York Street Railway Company, of Portsmouth, N. H., to succeed the late I. C. Libby, of Waterville.

MR. J. C. HUTCHINS, vice-president and general manager of the Detroit Citizens' Street Railway, has been elected president of the Detroit Electric Railway, to succeed the late Albert Pack.

MR. M. M. KOHN, general manager of the Oceanic Gas & Electric Company, Ltd., of Honolulu, H. I., is at the Hoffman House, New York. During his visit here, Mr. Kohn will make purchases in the mechanical and electrical lines

MR. WILLIAM WEAVER, of Ogden, manager of the Ogden Street Railway Company, of Ogden, Utah, has been appointed receiver of the Bear River Irrigation and Ogden Waterworks Company, to succeed William Adamson and S. S. Conklin.

MAJ. L. N. DOWNS, president of the Michigan Traction Company, of Kalamazoo, will remove to Philadelphia shortly to assume the presidency of the Railways Company General. This company recently secured control of the Michigan Traction Company.

MR. H. F. PARSHALL, the widely known consulting engineer of London, arrived in New York on Nov. 25, and will remain here for several weeks. He is accompanied by Mr. A. R. Monks, managing director of the British Thomson-Houston Company.

MR. FRANK M. HAYNES, president, purchasing agent and superintendent of the Lorain Street Railway Company, has tendered his resignation to accept a similar position in London, Eng., on lines recently acquired by A. J. Moxham and Tom L. Johnson.

MR. NELSON C. DRAPER, until recently mechanical engineer with the Central Railway Company, of Peoria, has been appointed constructing and mechanical engineer of the Peoria & Pekin Terminal Railway, with headquarters in Peoria. This company operates both steam and electric railways.

MR. J. BRODIE SMITH has been elected general manager of the Manchester Street Railway, of Manchester, N. H., to succeed Mr. E. P. Shaw, Jr., of Boston, who is forced to resign owing to the pressure of his other business connections. Mr. Smith will assume the general managership of the road Dec. 1.

MR. F. M. ZIMMERMAN, superintendent, purchasing agent and chief electrician of the Atlanta Railway Company, has resigned that position to accept a position with the Lorain Street Railway Company. Mr. Zimmerman will succeed Mr. Frank M. Haynes, who has connected himself with Mr. Johnson in his London project.

MR. E. J. BARNEY, president of the Barney & Smith Car Company, tendered his resignation as president of the company at the quarterly meeting of the directors, held Nov. 14. The resignation will take effect Jan. 1. At the meeting it was announced that the business on hand at the present time amounted to more than $2,000,000, and that the aggregate business which will be done this year will exceed that of last year by at least $600,000.

MR. A. N. CONNETT, engineer-in-chief of the works department of the Compagnie Francaise Thomson-Houston, of Paris, arrived in this country on Oct. 21, and returned to Paris during November. Mr. Connett is accompanied by Mr. J. A. Aubaret, engineer with the same company, who will remain in this country about six months studying street railway management in its different phases. Mr. Aubaret will reside in Washington while in this country.

CAPT. CHARLES E. HALL, master of construction for the Chicago City Railway from 1881 to 1897, and previously from 1857 to 1863 engineer in charge of nearly all the railways in Cuba, died in Chicago recently. Capt. Hall was born in Copenhagen, Denmark, and came to the United States as a child. He served in the war of the rebellion as captain in both the Fourth and Forty-ninth Wisconsin regiments.

MR. ROBERT F. FOX, formerly superintendent of the Scranton Railway Company, of Scranton, Pa., died a short time ago at his home in Meadville. Mr. Fox was well and favorably known in the East, and was at one time connected with the Brooklyn roads as assistant engineer. This position he resigned to accept the position at Scranton. From Scranton Mr. Fox went to Wil-

mington, Del., to assume the general managership of the lines of that city, and of Chester, Pa., which are controlled by the same interests as the Scranton company, but was compelled to resign the latter place owing to the failure of his health.

MR. F. J. O'DONOGHUE, superintendent of the Nashua, (N. H.) Street Railway, died at Nashua, Nov. 10, after a brief illness. Mr. O'Donoghue was well known in New England, and was connected with the Lowell & Suburban Railway before accepting the position at Nashua in 1896. Mr. O'Donoghue was born in Ireland forty-three years ago, but came to this country at an early age. He received his schooling in Boston and removed to Lowell when a young man, continuing to reside here until accepting the position in Nashua. His mother, two sisters and five sons survive him.

MR. R. W. BLACKWELL, of London, is in New York and will remain here for some weeks on business connected with his large European and American interests. Mr. Blackwell's business has reached such large proportions that additional working capital has become necessary, and a limited liability company, under the name of Robert W. Blackwell & Company, Ltd., was recently formed, with strong personal and banking alliances. New offices are being opened in the principal cities of Great Britain, and others will shortly be located on the Continent. Among the new parties interested in Robert W. Blackwell & Company, Ltd., are Col. Sir Charles Edward Howard Vincent, K. C. M. G., C. B., M. P., and Mr. Francis Henry Barker, chairman of the Associated Share Investment Company.

MR. GRANVILLE C. CUNNINGHAM, M. I. C. E., who has been for some years past managing director of the City of Birmingham Tramways Company, has been appointed general manager of the Central London Railway, one of the most important city transportation undertakings in the world (full description in the STREET RAILWAY JOURNAL for March, 1898, page 141). The cost of construction of this railway has been enormous, particularly in its city terminus at the bank, and as it bisects the great area of traveling London, passing under Bayswater Road and Oxford Street, it can hardly fail to secure an enormous revenue. Whether or not this revenue, gross and net, will be sufficient to earn a fair rate upon the investment, is the real question, but the company is to be congratulated on securing the services of Mr. Cunningham, whose experience in electric railroading during the past ten years has been second to that of few managers on either side of the Atlantic. Mr. Cunningham was for some years general manager and chief engineer of the Montreal Street Railway Company, one of the most successful and conservatively managed properties in North America.

COLONEL GEORGE B. M. HARVEY, president of the Atlantic Coast Electric Railroad Company and head of the Harvey syndicate, which recently purchased the street railway system of Havana, has been elected president of the publishing house of Harper & Brothers. Colonel Harvey is thirty-five years of age and a native of Vermont. After a newspaper experience commencing with the "Springfield Republican" and including the "Chicago Daily News," the "New York World" and the "Newark Journal," Colonel Harvey severed his connection with newspaper work in 1893 to engage in electric railroading, notably in Staten Island and in Eastern New Jersey. Previous to that time he had served on the staff of Governors Green and Abbett, of New Jersey, and had acted as Commissioner of Banking and Insurance of New Jersey. In a number of his railway enterprises he has been associated with Mr. William C. Whitney. In addition to his railway work and his connection with Harper & Brothers, he is vice-president of the Monmouth Trust & Safe Deposit Company, a director of the Lakewood Trust Company, a director of the Audit Company, a director of the Mechanics & Traders' Bank, of New York, vice-president of the National Salt Company and owner and editor of the "North American Review."

MAJOR RUSSELL B. HARRISON, formerly of Terre Haute, who has been a prominent and gallant officer during the recent Spanish war, returned to the United States on sick leave about Nov. 1, and will remain in this country from thirty to sixty days before returning to his post. Major Harrision has made a fine record during the war. He was originally appointed to the staff of General Fitzhugh Lee, in command of the 7th Army Corps, and was first detailed to act as Assistant Inspector General of the corps. A little later he became Chief Ordnance Officer, and had in charge the equipment of the corps with all ordnance necessary for their campaign. Still later he became Provost Marshal, with widely varied and important duties, having in charge the sanitary policing and sanitation of the camps, the regulation of the signal service system, etc. On the occupation of Havana he was placed in command of Morro Castle, being thus the first American officer to enter the castle and assume command. In April and May, 1899, the 7th Army Corps was mustered out of service, but Major Harrison was one of two or three officers retained in the service, and he became Inspector General of the Department of Santiago and Puerto Principe, under General Leonard Wood. In July there came an epidemic of yellow fever in his department, and while inspecting hospitals in the vicinity of Cuba about the middle of August, he succumbed to the fever, and had perhaps the most severe case ending in recovery known in the annals of medicine. On October 18 he was able to leave the hospital, and was put on sick leave and sent to New York. He left on November 5 for Omaha, where his wife has resided during his absence, and will remain there for some time to come.

MR. GARRETT A. HOBART, Vice-President of the United States, who died last month, was for a long time president of the Paterson (N. J.) Railway Company, and took an active interest in its management. It was largely through the personal attention which he gave the property, together with the efficient management of Mr. McAdoo, the company's general manager, that the property was brought to its present efficient state. Mr. Hobart was born June 3, 1844, at Long Branch, and was graduated from Rutger's College in 1863. He entered the legal profession, in which he soon secured success, as well as in business and politics. For eleven years he was chairman of the Republican State Committee of New Jersey, and beginning with 1884, was a member of the Republican National Committee. As presiding officer of the Senate he acted with great efficiency, and was also prominent in party councils, a fact which has not been true of most Vice-Presidents. In addition to his connection with the Paterson Railway Company, he was interested in many other corporations, engaged in transportation, banking and manufacturing.

GARRETT A. HOBART

AMONG THE MANUFACTURERS

A COMPANY has been incorporated in London, with a capital of $15,000, for the purpose of printing and publishing a European edition of the "American Machinist."

THE BURT MANUFACTURING COMPANY, of Akron, Ohio, has recently received a letter from the Seoul Electric Company, of Seoul, Korea, ordering a Cross Special No. 3 filter with a capacity of 30 gals. to 40 gals. per day.

THE GREEN ENGINEERING COMPANY, of Chicago, who are the manufacturers of the Green traveling grate described recently in the STREET RAILWAY JOURNAL, and are also contractors for complete steam plants, having opened an office in St. Louis, in room 642, Century Building.

THE BROWNELL CAR COMPANY, of St. Louis, is very busy on a number of orders, among them one for fifty-five new cars to be used by the Metropolitan Street Railway Company, of Kansas City. The shops are full of work from other orders as well, and the company reports an excellent outlook for the coming year.

THE SEGUINE-AXFORD VENEER COMPANY, of Newark, N. J., is rapidly extending its lines into every field where veneers are used. The company is giving particular attention to street car work, and is supplying, when specified, ceilings and other veneer work made with a guaranteed moisture-proof glue of their own make.

THE WALWORTH MANUFACTURING COMPANY, of Boston, has recently moved its main office from 16 Oliver Street to its new store, 128-136 Federal Street. The company has secured at this latter address fine offices, which have been fitted up in the best manner possible for conducting its large and constantly increasing business.

THE INTERNATIONAL BRAKE SHOE COMPANY, of Chicago, has recently received numerous inquiries regarding the diamond "S" brake shoe from foreign lands, with a view toward adapting it as standard. To care for this growing export trade the company has recently published pamphlets in the various languages for circulation abroad.

GEO. KISSAM & COMPANY, of New York, the well known advertising agents, have recently published a tasteful folder giving particulars of the International Traction Company, of Buffalo and Niagara Falls, the advertising on whose lines is controlled by this firm. The folder also presents a bird's-eye view of the entire system, with the Niagara Falls in the foreground.

THE UNION BOILER TUBE CLEANER COMPANY, of Pittsburgh, Pa., has just completed a contract for cleaning two Hazleton or porcupine-boilers having over 2000 tubes, one end of which is welded tight. These tubes were badly scaled, and the closed end required a special tool of unique design, as well as the use of the Union Boiler Tube Cleaner Company's special design of flexible shaft.

THE CLING-SURFACE MANUFACTURING COMPANY, of Buffalo, N. Y., reports a rapidly increasing demand for Cling-Surface, with recently large shipments to England and Mexico. Of the many testimonial letters sent in by users of this preparation for belts the Union Traction Company, of Philadelphia, says: "We have ordered a second can of Cling-Surface, which is evidence that we consider it satisfactory."

THE STERLING VARNISH COMPANY has just issued a small but interesting pamphlet on the subject of insulating varnish, which contains besides a good deal of valuable information, a number of fac simile letters of recommendation, orders, etc. An edition has been printed in French and German for distribution on the Continent, and all in this or foreign countries who desire to obtain a copy, will do well to address the company.

THE H. C. ROBERTS ELECTRIC SUPPLY COMPANY, of 831 Arch street, Philadelphia, Pa., has recently purchased the good will, stock and fixtures of the Franklin Electric Supply Company, of 506 Cuthbert Street. Mr. Roberts has had long experience and close connection with electric industry, and his company is in an excellent position to advise purchasers as to apparatus, as well as to supply them with various kinds of electrical goods.

THE CLEVELAND CRANE & CAR COMPANY, of Cleveland, Ohio, has recently published a tasteful catalogue descriptive of the electric cranes built by it for railway power stations and factories. These cranes have had a most successful record where they have been installed, especially in power stations where electric power is so easily available and most convenient. The cranes are built in all types, including traveling cranes, jib cranes, locomotive cranes, etc.

THE DE WITT SAND BOX COMPANY, of Lansingburg, N. Y., has recently closed a contract with the Third Avenue Railroad Company, of New York, for 840 sand boxes. The De Witt Sand Box Company is a recent organization which will manufacture the De Witt sand box, formerly made by E. F. De Witt & Company. The change has been made to increase the manufacturing facilities of the firm, which has recently been taxed, owing to the large number of orders received.

THE BERLIN IRON BRIDGE COMPANY shipped from its plant at East Berlin, Nov. 15, a train load, comprising about twenty-seven cars of structural material consigned to the United States Commission at Paris, France. This material will constitute a very important element in the American exhibit at the Paris Exposition, and is for the steel framework of a machine shop to be used exclusively by the American exhibitors of iron and wood-working machinery at the exposition.

THE EIGHTEENTH EDITION of the Electrician Electrical Trades' Directory and Hand Book for 1900 is now in preparation, and is to be ready in January, 1900. This well-known British publication is a carefully compiled list of British, colonial and foreign engineers, manufacturers, lighting and tramways companies, and, in fact, all engaged in electrical pursuits throughout the world. Correspondence should be addressed to the "Electician" office, Salisbury Court, Fleet Street, London, E. C.

THE SOUTHERN PACIFIC COMPANY has issued a trio of pamphlets entitled "Shasta Route," "California South of Tehachapi" and "Wayside Notes Along the Sunset Route." The pamphlets are well gotten up and contain an industrial, geographical and scenic description of the interesting features along the company's route. The illustrations are especially clear and attractive. A map of California, with a brief description of its resources, attractions, topography, climate, etc., is also published by this company.

THE GOLD CAR HEATING COMPANY, of New York, has recently published a large circular descriptive on one side of its system of electric heaters, and on the other side giving the salient points of the recent suit between the Consolidated Car Heating Company and the Palmer & Monson Street Railway Company, in which it was decided that the Gold system was not an infringement of the patents of the former company. Mention of this decision was given in the last issue of the STREET RAILWAY JOURNAL, and a reproduction of this circular is published elsewhere in this issue.

J. G. BRILL COMPANY, of Philadelphia, has just secured an order from the Union Traction Company for 150 cars. One hundred and ten of these cars are to be of the twelve-bench open type, with an aisle through the center; the other forty are fourteen-bench open cars, also with center aisle. Both are to have the Union Traction Company's standard finish, and to be of the same style and finish as furnished the Union Traction Company by the Brill Company during the past summer. Westinghouse No. 38 motors will be used on the twelve-bench cars and four Westinghouse No. 3 motors on the fourteen-bench cars.

GEORGE W. LORD, of Philadelphia, manufacturer of Lord's Boiler Compound, after twenty-three years at his former location, moved on Dec. 1, to his new plant, 2238 to 2250 North Ninth Street, Philadelphia. The new plant covers a ground space of 150 ft. x 175 ft., and consists of a three-story and basement brick building, with foundation and walls sufficiently strong to allow the addition of three more stories, should that space be required any time in the future. The equipment will include the latest apparatus for manufacturing the chemicals used in the preparation of the many formulas of Lord's Boiler Compounds.

THE FRANK M. PIERCE ENGINEERING COMPANY, of New York, reports a very active business, largely as a result of Mr. Pierce's extensive foreign travel within the last few years. During the last month the company reports contracts closed as follows: Four 500-kw. direct-connected, cross-compound, heavy duty, St. Louis Corliss railway engines; one 500-kw. direct-connected, simple, heavy duty, St. Louis Corliss railway engine; twenty-two engines on order to supply the company's English trade, and one electric lighting power plant for equipping a central station in one of Uncle Sam's new island possessions.

THE HAM SAND BOX COMPANY, of Troy, N. Y., reports a large number of recent orders. These boxes are used extensively abroad, as well as in this country, as shown by the following list of foreign railways on which the boxes have recently been applied: Bolton Corporation, Lancashire; Blackpool & Fleetwood Tramroad Company, Potteries Electric Traction Company, Corporation of Liverpool, Dublin United Tramways Company, Waterloo & City Railway, London; Corporation of Sheffield, Liverpool Overhead Railway Company, Carlisle Tramways Company, Corporation of Sunderland, Corporation of Dundee, Corporation of Southport, and Great Grimsby Street Tramways Company.

THE CLONBROCK STEAM BOILER COMPANY, of Brooklyn, manufacturers of the Morrin "Climax" steam boiler, reports that the Climax boilers, which the company had on exhibition at the Trans-Mississippi and International Exposition, Omaha, Neb., 1898, and the Greater American Exposition, Omaha, Neb., 1899, have all been sold to the following parties: The Council Bluffs Street Railroad Company, Council Bluffs, Ia., one 500-h.p. and one 250-h.p. boiler; the Madison Street Railroad & Electric Light Company, Madison, Ia., one 250-h.p. boiler, and the International Packing Company, Omaha, Neb., for its new plant at Sioux City, Ia., three 500-h.p. and one 200-h.p. boilers.

EXPERIENCED HELP, at a time when required, is an important matter with railway companies. Good men are required, and an emergency creates a demand that must be promptly filled. E. G. Johnson, who has been for several years Superintendent and General Manager of the Philadelphia & Bryantine Railroad and the Bryantine Transportation Company, has opened an office in the St. James' Building, Broadway, New York, and is in touch with the railways and with the best class of labor, which can be vouched for and recommended. Application to Mr. Johnson will be regarded as confidential and immediate response given. No

charges are made for the service rendered and personal attention is given by Mr. Johnson to all business intrusted to his office.

ANNOUNCEMENT is made of the organization of the New York Air Compressor Company under the laws of the State of New Jersey. The capital stock of the company is $100,000, and a complete foundry and machine shop plant has been purchased on the line of the New York & Greenwood Lake Railroad at Arlington, N. J. Contracts have already been let for a full modern equipment of tools. It is intended to manufacture a complete line of air compressing machinery at the new plant. The officers of the company are: J. W. Duntley, president; Alexander MacKay, vice-president; W. P. Pressinger, secretary and treasurer. The directors are: J. W. Duntley, Alexander MacKay, W. P. Pressinger, William B. Albright, W. O. Duntley, Thomas Aldcorn and Austin E. Pressinger. The New York offices of the company are at 120 Liberty Street.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, of Cincinnati, reports fifty-five orders for the month of October, the machine ranging in size from the smallest to 300 kw. capacity. A repeat order was received from the Maryland Steel Company, of Sparrows Point, Md., this making the fifth order, and being for a 300-kw. generator and several motors. Orders were received from the London, England. "Star," and the St. Petersburg, Russia, "Novia Wremia," two of the most important papers of the respective cities, for the Bullock "teaser" equipment for operating newspaper presses. Two 300-kw. alternating current generators were shipped to the Wilson Aluminum Company, of Holcombs Rock, W. Va., to be used in the manufacture of ferro-chrome, an electro-chemical product used in the manufacture of chrome steel.

THE NEW CAR HOUSE at Port Chester, N. Y., for the Port Chester Street Railway Company, will be furnished by the Berlin Iron Bridge Company, of East Berlin, Conn. This building will be one of the largest of its kind in the country. The Berlin Iron Bridge Company also reports a large number of other orders. Among them are a new pier shed and dock, 40 ft. x 600 ft., at Providence, R. I., for the Clyde Steamship Company, and some new work for William Cramp & Sons, Ship & Engine Building Company. The work for this company will include a new machine shop 142 ft. wide and 350 ft. long, three stories in height. All the floors, including the gallery floors, to be controlled by electric traveling cranes. The building will be of steel frame-work, the outside walls of brick, and will be one of the largest and most complete machine shops in the world.

THE AMERICAN STEEL & WIRE COMPANY, of Chicago, has issued a circular to its customers explaining that the partial destruction on Nov. 4 of one of its plants at Waukegan by fire will not seriously delay the filling of orders. The circular says: " The fire affected particularly the finishing end of the plant, the rolling mill not being damaged in any respect. Our warehouse, with a fair stock of goods, was also saved. We have already made arrangements for the execution by our other plants of unfilled orders at Waukegan, and desire to assure you that all orders now placed with us which have been lodged at Waukegan for shipment, will be taken care of by shipment from other plants with very little, if any, delay; and all future orders will receive our prompt and careful attention as heretofore. We therefore solicit a continuance of your future favors, and are in position to respond promptly."

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY and the Westinghouse Air Brake Company, of Pittsburgh, have published during the last month two very tasteful catalogues, one relating to the new electric railway motors of the former company, the other to the electro-pneumatic system for controlling trains, of the Air Brake Company. The new motors described include the 68, 69, 56, 70 and 50-C., all of which were described in the October issue of the STREET RAILWAY JOURNAL. The catalogue includes as well a number of attractive views of some typical Westinghouse power stations, and is very handsomely printed and illustrated. A description of the Westinghouse electro-pneumatic system of control, which is the subject of the second pamphlet, was also published in the October issue. The catalogue, however, gives a large number of new engravings, and will be found of interest to all electric railway engineers.

THE WESTERN ELECTRICAL SUPPLY COMPANY, of St. Louis, has recently taken the exclusive territorial agency for the Multiplex Reflector Company. These corrugated reflectors and head-lights are claimed to be an entirely new departure and the latest and best thing in the reflector line yet produced. They are said to produce 300 per cent more light, both in intensity and volume, than any other plain or parabolic reflector on the market, and the company invites comparison to substantiate this claim. They are especially adapted for street railway work and certainly deserve the consideration of anyone on the market for a first-class and strictly up-to-date head-light. The Multiplex Reflector Company makes an electric arc head-light with automatic regulation, and claimit to be the only self-regulating arc head-light made. These head-lights are so constructed that no amount of jarring or vibration will disturb their adjustment or affect the light in the least. The manufacturers are always glad to send these head-lights out on trial, or for competitive tests.

THE JACKSON & SHARP COMPANY, of Wilmington, Del., has recently shipped to the Perth Tramways Company, Ltd., Perth, Western Australia, five 18 ft. closed car bodies, and to the Buenos-Aires & Belgrano Tramway Company, Buenos-Aires, Argentina, twenty convertible car bodies, and five ten-bench open cars of the standard type used in this country. Its domestic orders have also been considerable. Among other work the company has just completed six 30 ft. cross seat cars for the Bridgeport Traction Company, Bridgeport, Conn. These cars are very fine in every respect. The interior finish is of mahogany. The seats are upholstered in crimson plush, and have bronze handles on the corners in place of the overhead hand straps. They have upper and lower sash, the top sash being permanent, and glazed with embossed glass. The lower sash when down gives a very large opening, which makes the car very desirable for summer as well as winter service. These cars have a seating capacity of forty persons each. They are equipped with twelve heaters. The platforms are vestibuled, and have double side folding doors. The cars are mounted on short wheel base trucks, and have four motors. They are equipped with Sterling safety brakes. The Brunswick Traction Company, New Brunswick, N. J., has also recently received six 28-ft. closed cars from the Jackson & Sharp Company.

New Publications

Verbatim Report of the Third Regular Annual Meeting of the Street Railway Accountants' Association of America. Published by the Street Railway Accountants' Association of America.

The verbatim report of the Chicago convention of the Street Railway Accountants' Association of America is just at hand, and Secretary Brockway certainly deserves great credit for the promptness with which this report has appeared so soon after the annual convention. The report contains 160 pages, and has as a frontispiece an excellent likeness of President Calderwood.

Report of the Eighteenth Annual Convention of the American Street Railway Association. Published by the Association. 219 pages.

The official report of the Chicago Convention has been published with the usual promptitude, and members of the association can have the satisfaction of having the printed report before them within less than a month from the close of the convention. It is needless to say that this adds very much to the value of the report and the secretary should have due credit therefor. Some of the diagrams and the banquet menu are reproduced in different colors, and the frontispiece, a portrait of ex-President Sergeant, is an excellent one.

Trade Catalogues

Insulating Varnish. Published by the Sterling Varnish Company, of Pittsburgh, Pa. Illustrated.

Interior Conduit Catalogue No. 75. 148 pages. Illustrated. Published by the Sprague Electric Company, of New York.

Cranes and Electric Hoists. 20 pages. Illustrated. Published by the Cleveland Crane & Car Company, Cleveland, Ohio.

Westinghouse Railway Motors. 34 pages. Illustrated. Published by the Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa.

Catalogue No. 64. Lundell Generators, Direct Connected and Belted Types. 36 pages. Illustrated. Published by the Sprague Electric Company.

Westinghouse Electro-Pneumatic System for Controlling Railway and Other Motors. 38 pages. Illustrated. Published by the Westinghouse Air Brake Company, Pittsburgh, Pa.

Application of Storage Batteries in Railway and Power Plants. Circular No. 55. 12 pages. Illustrated. Published by the Electric Storage Battery Company, of Philadelphia.

Digest of the Contents of this Issue

GERMAN, FRENCH AND SPANISH

Inhalts-Verkürzung—October, 1899.

Elektrisches Bahnwesen in Amerika, wozu Chicago einen Beleg liefert. . . . . . [Seite 613.]

Die Obergrund-Bahnnetze in Chicago werden von zehn und die Hochbahnlinien von fünf unabhängigen Gesellschaften betrieben. Mehrere der hauptsächlichsten Linien weisen noch Seilbetrieb auf, doch ist die grössere Meilenanzahl bereits mit Elektrizität ausgestattet, und beabsichtigt man, die Umwandlung des Seilbetriebs in elektrischen sobald als möglich vorzunehmen. Pferdebahnen sind fast ganz aus Chicago verschwunden, indem da nur noch einige Nebenlinien der mit Seil betriebenen Linien existiren. Die Hochbahnlinien werden sämtlich mit Elektrizität betrieben und bilden bei weitem das ausgedehnteste Hochbahnnetz der Welt. Natürlich giebt es in Chicago eine grosse Anzahl Kraftstationen, um alle unabhängigen Bahnnetze in Betrieb setzen zu können; von den meisten ist eine Abbildung beigegeben, woraus die Anordnung der Maschinerie u. s. w. erhellt; auch sind sie diagrammartig veranschaulicht, um auf solche Weise die relativen Grössen der Stationen sofort hervortreten zu lassen. Fast sämtliche grosse Kraftstationen werden ohne Kondensation betrieben, und giebt es in Chicago nur drei oder vier Stationen mit Kondensation. Die Unmöglichkeit, eine genügende Wasserzufuhr zu einem mässigen Preise zu erhalten, hat zu der Verwendung von Kühlanlagen und Tischen geführt, mittelst deren das Wasser für Kondensation mehrere Male benutzt wird. Wiewohl der Oberbau in Chicago, gerade nichts Wunderbares aufweist, verdient er dennoch einige Autmerksamkeit und zwar besonders hinsichtlich des Umgiessens von Schienenstössen, ein Verfahren, worin man es hier zu einem hohen Grade von Vollkommenheit gebracht hat. Das Oberleitungssystem ist, wenn auch einfach, sehr gut, und war man weniger darauf bedacht, ihm ein schönes als vielmehr ein anspruchsloses Aussehen in den Strassen zu verleihen. Den Schluss dieses Artikels bildet die Beschreibung nebst beigefügten Abbildungen der Konstruktionsarten, wie sie bei der neuen Nordwest-Hochbahn zur Anwendung kamen.

Elektrisches Bahnwesen in Deutschland. Von Louis J. Magee. [Seite 647.]

Dieser Artikel enthält eine sehr werthvolle Beschreibung deutschen Bahnwesens aus der Feder des Betriebsleiters der Union Elektricitäts-Gesellschaft, einer der grössten Fabrikgesellschaften in Deutschland. Das Besitzrecht von deutschen Trambahnen wird ausführlich erörtert, und werden die Beziehungen der bedeutenden Finanz-Syndikate oder Gruppen zu der Strassenbahn-Industrie dargelegt, und kann man den Einfluss, den diese Gruppen auf die rasche Entwicklung Deutschlands ausgeübt haben, wohl kaum über schätzen. Die Haupteigenthümlichkeit des deutschen Bahnwesens, worin es sich vom amerikanischen unterscheidet, liegt in der Benutzung des gemischten Systems bei elektrischem Betrieb, wobei die Wagen im Mittelpunkte der Stadt durch Akkumulatorenbatterien und in den Umgebungen durch das System mit oberirdischer Stromzuführung fortbewegt werden. Noch Etwas, was Deutschland thut, und was weder in Amerika noch sonstwo in der ganzen Welt in demselben Grade geschieht, ist das Errichten von dekorativen Masten, von kombinirten Fahrdraht- und Beleuchtungspfosten u. s w. Herr Magee giebt weiterhin sehr interessante detaillirte Schilderungen, was Kraftstationen, Gleis, oberirdische Leitung, rollendes Material etc. anbetrifft: und aus Allem geht hervor, dass Deutschland die Wissenschaft der Elektrotechnik auf eine hohe Entwicklungsstufe gebracht hat.

Elektrisches Bahnwesen in Grossbritannien. Von Sidney H. Short. [Seite 663.]

Prof. Short hat in diesem Artikel viele der hauptsächlichsten Eigenthümlichkeiten des britischen Bahnwesens zusammengestellt und setzt die Schwierigkeiten auseinander, die der Entwicklung der Industrie in jenem Lande bis auf den heutigen Tag hindernd im Wege standen; es war dies eine Folge der durch die Parlamentsakte auferlegten Beschränkung und des wachsenden Verlangens nach Eigenthumsrecht, wie es die Stadtbehörden den Privatunternehmungen gegenüber kundgaben. Die technischen Einzelheiten über Oberbau, oberirdisches Leitungssystem, rollendes Material u. s. w. sind sorgfältig in Wort und Bild wiedergegeben.

Finanzielle Charakteristiken der bedeutenden Stadt-Bahnnetze der Welt. Von Edward E. Higgins. . . . . [Seite 680.]

Eine Sammlung der Statistiken betreffs Meilenanzahl, Kapitalanlage, Einnahmen und Ausgaben des Bahnnetze in Städten von mehr als 500000 Einwohnern in allen Ländern der Welt, in solcher Weise angeordnet, dass daraus der verhältnismässige Gewinn sowie auch die günstigen Gelegenheiten für Kapitalanlagen erhellen.

Elektrisches Bahnwesen in Oesterreich-Ungarn. Von E. A. Ziffer. . . . . [Seite 685.]

Die erste elektrische Bahn in Oesterreich für Personendienst wurde i. J. 1883 eröffnet und war 4 km lang; die in Ungarn i. J. 1889. Letztere Linie wurde nach dem Systeme mit unterirdischer Stromzuführung gebaut. Diese Leitung wird auf Seite 687 veranschaulicht. Das System kommt in Budapest in ausgedehntem Maasse zur Verwendung und soll auch in Wien installirt werden. Im Allgemeinen jedoch benutzt man das Fahrdraht-System. Konzessionen werden Privatgesellschaften von der Regierung bewilligt, doch ist die Dauer derselben auf sechzig Jahre beschränkt. Stadtgemeinden besitzen ebenfalls das Recht zum Bauen und Betreiben von Strassenbahnen. Auch sind alle Bahnen von untergeordneter Wichtigkeit für einen Zeitraum von zwanzig Jahren von Staatssteuern und in einigen Fällen von städtischen Abgaben befreit. Sodann giebt der Verfasser ein Verzeichnis der elektrischen Bahnen, nebst deren durchschnittlichen Länge, Spurweite, Personenbeförderung und Einnahmen. In den Städten sind die Schienen entweder auf Beton oder Schotter bis zu einer Tiefe von 30 cm gelegt, und beträgt deren Gewicht 34 bis 43 kg pro m. Ausserhalb der Stadtgrenzen benutzt man Vignoleschienen im Gewichte von 21 bis 23 kg pro m auf Holz- oder Metallschwellen. Der Verfasser beschreibt weiterhin das Verfahren bei Schienenverbindungen, Speiseleitungen und Masten. Der Fahrdraht ist gewöhnlich hartes, gezogenes Kupfer und 7 bis 8,25 mm im Durchmesser. Die Bahn von Baden nach Böslau benutzt Siliziumbronzedraht, dessen Durchmesser 7 mm beträgt. In manchen Fällen ist der obere Theil des Fahrdrahts mit einer hölzernen Schutzvorrichtung, die durch Metallklemmen in ihrer Lage festgehalten wird, bedeckt, um zu verhüten, dass herunterfallende Telephon- und Telegraphendrähte mit dem Trolleydraht einen Kontakt herstellen. Der am meisten benutzte Wagen ist der sogenannte Hamburger Typus, mit langer Plattform an jedem Ende und mit Sitzen für 20 Personen versehen. Die Gesamtlänge beträgt 8,4 m. In kleineren Städten variirt diese Totallänge zwischen 5,8 and 7 m. Der Verfasser giebt dann eine Beschreibung der verschiedenen Typen von Stromabnehmern oder Kontaktrollen. Die Fahrgeschwindigkeit ist in allen Fällen von den Behörden vorgeschrieben und beläuft sich gewöhnlich auf 15 km pro Stunde. In Strassen, wo wenig Verkehr herrscht, darf die Fahrgeschwindigkeit auf 18 km erhöht werden, muss jedoch in Strassen, die eng sind und in denen beträchtlicher Verkehr herrscht, auf 10 km reduzirt werden. In den Vorstädten ist eine Fahrgeschwindigkeit von 25 bis 30 km gestattet. Die Mehrzahl der grossen Kraftstationen arbeiten mit Kondensation und benutzen direkt gekuppelte Einheiten. Die Kessel sind solche des Wasserröhren-Typus, und der Kohlenverbrauch pro Kilowattstunde schwankt zwischen 0,8 und 5 kg. Ekonomiseure kommen manchmal zur Verwendung, und werden Speisewasser-Heizapparate stets benutzt. Schliesslich giebt der Verfasser noch eine kurze Beschreibung der industriellen und Bergbau-Bahnen.

Elektrisches Bahnwesen in Argentinien. Von E. Manville. [Seite 693.]

Herr Manville, ein Mitglied der wohlbekannten Ingenieur-Firma von Kincaid, Waller & Manville in London, die als Ingenieure bei dem Baue gewisser Trambahnen in Buenos Ayres fungirt haben, beschreibt die Bedingungen, unter denen Konzessionen für Trambahnen in Argentinien erlangt werden, sowie auch die zu überwindenden physikalischen und sonstige Probleme. Es herrscht in Argentinien eine bedeutende Abneigung gegen die Bewilligung von Konzessionen, die von langer Dauer sind, und die Gesellschaften stehen entschieden unter der Kontrolle der Stadtbehörde, welche für die Instandhaltung der Wegepflasterung, worin die Trambahnen liegen, eine Steuer von sechs Prozent der Bruttoeinnahmen auferlegt und den Trambahngesellschaften ausserdem noch andere Lasten, die zwar schwer aber nicht prohibitiv sind, aufbürdet. Drei Arten von Oberbau kommen — je nach dem Betrieb — in Buenos Ayres zur

Verwendung. Bei einer Art lagern die Schienen vollständig auf Beton, bei einer anderen auf Längsschwellen von Beton und bei der dritten Art auf einfachen Querschwellen ohne Beton. Bei dem Vertheilungssystem ist die höchste gestattete Spannung sehr gering, und wird dieses Resultat durch die Anwendung von negativen Zusatzmaschinen bewerkstelligt, während die positiven Leitungen, die nach den äussersten Enden des Bahnnetzes führen, positive Zusatzmaschinen besitzen. Das System mit oberirdischer Stromzuführung und das mit unterirdischer Stromzuführung in Argentinien sind beide ausgezeichnet; auch das rollende Material ist gut. Kraft wird hauptsächlich den dortigen Kraftstationen, von denen dort mehrere in grossem Maassstabe arbeiten, entnommen.

Die Ausführung von Bahnmotoren. Von W. B. Potter. [Seite 701.]

Der Verfasser ist Chefingenieur der Bahnabtheilung der General Electric Company. Er erklärt, dass die Pferdestärken der von dieser Gesellschaft gebauten Motoren auf einer willkürlichen Norm, welche auf einem temporären Steigen der Temperatur des Motors—75 Grad C. in einer Stunde unter Belastung—beruht, basirt sind, wobei die Temperatur der umgebenden Luft zu 25 Grad C. angenommen wird. Der Motor kann nicht beständig zu diesem Leistungsgrade in Betrieb gehalten werden, doch kann man ihn kurze Perioden lang ohne Nachtheil über dieses Maass hinaus arbeiten lassen. Die durchschnittliche Pferdestärke, die ein Motor den Tag über entwickelt, sollte nicht grösser als 30 Prozent der oben angegebenen Rate sein. Wo man elektrische Bremsen benutzt, sollte der Motor eine 20 bis 25 Prozent grössere Leistungsfähigkeit besitzen als da, wo dieselben nicht zur Verwendung kommen. Unter gewöhnlichen Stadtverhältnissen sollte die in Motoren erforderliche Pferdestärke das Gesamtgewicht in Tonnen multiplizirt mit der maximalen Fahrgeschwindigkeit in Meilen pro Stunde auf ebener Fläche und durch 5 dividirt betragen. Wenn die Maximal-Geschwindigkeit nicht bekannt ist, so kann für dieselbe die doppelte planmässige Fahrgeschwindigkeit angenommen werden. Indessen sollte man diese Regel mit Vorsicht anwenden, da sie nur die minimale Leistung unter gewöhnlichen Verhältnissen anzeigt. Bei gewöhnlichem Strassendienst beträgt die Zugkraft während Beschleunigung zwischen 10 und 15 Prozent der beförderten Belastung; bei Hochbahn- und Vorortbetrieb beträgt sie gewöhnlich 5 bis 7½ Prozent, während sie bei Güterbeförderung, wobei langsame Fahrgeschwindigkeiten angewendet werden, 1½ oder 2 Prozent nicht übersteigen mag. Bei gewöhnlichem Dienst sollte das Gewicht auf den Laufrädern wenigstens sechs Mal das der erforderlichen Zugkraft sein. Die annähernde Leistung einer Kraftstation für irgend einen gegebenen Dienst beträgt ungefähr 100 Wattstunden pro Tonnenmeile bei gewöhnlicher Fahrgeschwindigkeit.

Elektro-pneumatisches Kontrolsystem für Bahn- und andere Motoren. . . . . . [Seite 703.]

Dieses System kommt in Pittsburgh und Wilmerding zur Verwendung, wo zwei oder mehrere Motorwagen zu einem Zuge zusammengestellt sind und jeder Wagen seinen eigenen Kontroller hat; dadurch entsteht die Nothwendigkeit, die Kontroller in genauen Synchronismus zu stellen, um sämtliche Motoren mit derselben Geschwindigkeit laufen lassen zu können. Die Thätigkeit sämtlicher Kontroller wird von der vorderen Plattform des ersten Wagens aus geleitet und durch Luftkraft bewerkstelligt. Oben an jedem Kontroller befinden sich zwei Cylinder, von denen einer einen Sperrkegel trägt, der in ein Sperrrad, welches oben am Kontroller angebracht ist, eingreift. Die Luftcylinder werden durch eine kleine elektrische Batterie, die mittelst eines kleinen elektrischen Ausschalters vorn im Führerstand in Betrieb gesetzt wird, übereinstimmend in Aktion gebracht, Der zweite Luftcylinder dient dazu, um den Kontroller auf O-Stellung zurückzubringen, und wird ebenfalls durch den Motorführer auf der vorderen Plattform in Thätigkeit gesetzt. Der Momentausschalter ist so angeordnet, dass er die Kontroller, falls er sich öffnen sollte, auf die Ausschaltungsseite wirft. Wenn man die Luftbremsen ansetzt, kehren sämtliche Kontroller automatisch nach der Ausschaltungsseite zurück. Der Luftkompressor, den eine Abbildung veranschaulicht, ist ebenfalls von neuartigem Typus und besteht aus einer rotirenden Verbundpumpe, die von einem kleinen Motor direkt getrieben wird. Die in den Drehgestellen für die Motoren verwendete Federunterlage ist von derjenigen des Wagens vollständig abgesondert gehalten.

Bedeutender Fabrikant elektrischer Artikel. . [Seite 708.]

Besondere Spezialität bilden Draht und Schienenverbindungen.

Apparate für Kraftübertragung in New York. . [Seite 709.]

Gegenstand der Beschreibung bilden in diesem Artikel die Wechselstrommaschinen, die rotirenden Umwandler und Umformer, die von der Metropolitan Strassenbahngesellschaft bei ihrer Anlage verwendet werden sollen. Die Krafterzeugungsmaschinen sind solche mit rotirenden Feldern und äusseren feststehenden Ankern. Jede Maschine besitzt eine Leistungsfähigkeit von 2500 kw und wird einen Dreiphasenstrom von 6600 Volt bei einer Frequenz von 25 Perioden pro Sekunde erzeugen und mit 250 Umdrehungen in der Minute laufen. Das umlaufende Feld weist 40 Pole auf, ist direkt auf der Maschinenwelle montirt und auch gut ventilirt. Jede Spule ist mit einem Wechselstrom von 25000 Volt geprüft. Der Anker ist aus Gusseisen hergestellt und mit gleitenden Grundplatten versehen, so dass man ihn seitwärts schieben kann, bis er von dem umlaufenden Feld ganz entfernt ist; auf diese Weise wird das Inspiziren und Repariren des Ankers sowohl wie auch des Magnetfelds wesentlich erleichtert. Das rotirende Feld besteht aus einem Stahlringe, der fest mit einem gusseisernen Rahmen verbolzt ist; dieser Rahmen ist keilartig an der Maschinenwelle befestigt. Die erniedrigenden Umformer in den Stationen, wo sich die rotirenden Umwandler befinden, sind für eine Leistung von je 250 kw bestimmt, und werden drei dazu benutzt, um jeden rotirenden Umwandler in Gang zu setzen. Die primäre Wickelung des Transformators ist auf 6000 Volt und die sekundäre auf 350 Volt berechnet. Die Umformer werden durch Luft, welche durch die Umformer geblasen wird, gekühlt; bei voller Belastung stellt sich der Nutzeffekt der Umformer auf 98,22 Prozent. Die rotirenden Umwandler besitzen eine Leistungsfähigkeit von je 990 kw und arbeiten mit 214 Umdrehungen pro Minute. Das Magnetfeld besitzt achtzehn Pole, die aus Gusseisen angefertigt sind. Die Ankerwickelung ist aus Kupferstäben hergestellt. Die Bürsten an der Gleichstromseite des rotirenden Umwandlers sind aus Kupfer, und arbeitet der rotirende Umwandler als Sechsphasen-Maschine. Das Anlaufen der rotirenden Umwandler wird von dem Gleichstrom mit Hülfe von Strom, den Akkumulatorenbatterien liefern, bewerkstelligt.

Neuer Typus einer Compound Maschine. . . [Seite 711.]

Die charakteristische Neuerung dieser Maschine besteht der Hauptsache nach in der Art und Weise, wie die Einströmungsventile an den Niederdruck-Cylindern in Thätigkeit gesetzt werden. Diese Ventile werden theils von einem festen Excenter an der Maschinenwelle und zum Theil auch von demselben Excenter, welches die Thätigkeit der Ventile an dem Hochdruck-Cylinder bewirkt, in Thätigkeit gesetzt. Die letztgenannten Ventile werden natürlich von dem Regulator kontrollirt. Man behauptet, dass durch ein solches Verfahren, die Niederdruck-Ventile in Thätigkeit zu setzen, die Nachtheile, welche dadurch entstehen, dass man sie ganz und gar von einer festen excentrischen Scheibe an der Maschinenwelle oder genau in Uebereinstimmung mit den Hochdruckventilen in Thätigkeit setzt, vermieden werden.

Pufferbatterien für Bahnverkehr. . . . . . [Seite 712.]

Die Beschreibung betrifft eine wohlbekannte englische Pufferbatterie. Die Platten werden mittelst des Planté'schen Prozesses, mit Schwefelsäure allein, gebildet, was ungefähr sechs Wochen in Anspruch nimmt. Sämtliche Platten sind mit einer langen Stange ohne Schrauben verbunden. An der Seite der Zellen kommen mit Ausnahme von Glas und Blei keine anderen Stoffe zur Verwendung, und werden diese Pufferbatterien unter Garantie zu einem Preise, der 3 bis 6 Prozent ihrer Kosten beträgt, in Stand gehalten. In Grossbritannien und anderen Ländern werden sie als Regulirungs-Vorrichtung in Kraftstationen in ausgedehntem Maasse benutzt.

Neuer Typus von Strassenbahnmotoren. . . [Seite 713.]

Zur Beschreibung kommen fünf Motortypen, die vor Kurzem von derselben Gesellschaft in den Markt gebracht sind und in Bezug auf Grösse von 30 PS bis zu 150 PS variiren. Die ersten zwei beschriebenen (No. 68 und No. 69) sind so eingerichtet, dass der ganze Motor, wenn man vier Bolzen entfernt und ihn von den Federn, die ihn tragen, loskuppelt, mittelst einer Hebeschraube, die in einen Schacht läuft, unten von dem Wagen her entfernt werden kann. Ein mit diesen Motoren ausgerüsteter Wagen wechselt die Motoren jeden anderen Tag, damit eine sorgfältige Inspizirung daran vorgenommen werden kann. Sie sind sowohl zum Schmieren mit Fett als auch zur Oelschmierung eingerichtet, und wird das Oel zwischen den Transmissionsrädern an solchen Stellen eingeführt, wo der geringste Druck herrscht. Der dritte Motor (No. 56) ist dazu bestimmt, auf dem Wagen inspizirt und nicht oft demontirt zu werden. Derselbe ist aus zwei Theilen, die in der Mitte mit Scharnieren versehen sind, zusammengesetzt, und durch das Abschrauben eines Bolzens vermag man die untere Hälfte in einen Schacht hinabzuschwingen; dabei kann der Anker entweder in der oberen oder unteren Hälfte—je nach Wunsch—zurückbehalten werden. Der vierte Motor (No. 70) und der fünfte Motor (No. 50 C) sind für schweren Dienst bestimmt und besitzen je eine Leistungsfähigkeit von 110 bis 150 PS. Ausserdem sollen sie auf Drehgestellen montirt werden, die man unter dem Wagen herausschieben kann, so dass man dann die obere Hälfte des Motors zu entfernen im Stande ist. Sämtliche Motoren sind gegen Staub und ablaufendes Wasser geschützt und mit laminirten Polenden versehen, die, anstatt in die Joche eingegossen zu sein, mit denselben verbolzt sind.

Schienenstösse. Von W. F. Ellis, C. E. . . . [Seite 715.]

Die frühere Form von Laschenstossverbindung wird auf Fig. 2 und 3 veranschaulicht. Diese hat bei der gewöhnlichen Gleiskonstruktion durch die auf Flg. 1 und 4 dargestellte Form eine Verbesserung erfahren. Der Verfasser hält dieselben nicht für wünschenswerth, indem er unter anderen Gründen auch den Grund anführt, dass die Schiene in die Schwelle—wie aus Fig. 4 erhellt—einschneidet, was zur Folge hat, dass die Lasche die Bolzen zu straff anzieht. Fig. 5 und 6 veranschaulichen einige Uebelstände, welche sich mit der gewöhnlichen Lasche ergeben und die dann entstehen, wenn die Löcher nicht richtig gebohrt sind. Um diesem Uebelstande abzuhelfen, empfiehlt der Verfasser den auf Fig. 7 und 8 abgebildeten Stoss, der an Vignole-Schienen angebracht wird. Fig. 9 stellt den gewöhnlichen Stoss dar, den man an der amerikanischen Normalschiene anbringt, und Fig. 10 den verbesserten Schienenstoss.

Neue Koke-Werke. . . . . . [Seite 716.]

Beschrieben wird eine neue Fabrik, die sich mit der Herstellung von Kokebürsten befassen will. Dieselbe liegt in den Kohlen- und Koke-Gegenden Pennsylvaniens, und soll in den Werken zum Brennen und anderen Zwecken Naturgas in ausgedehntem Maasse zur Verwendung kommen.

Bahnwagentritte, auf denen man nicht ausgleiten kann. [Seite 716.]

Derartige Tritte sind aus Stahlrippen angefertigt, wobei Blei in die offenen Höhlungen gegossen ist. Sie werden in ausgedehntem Maasse für Bahnwagentritte und Stufen, die zu den Hochbahnstationen hinaufführen, benutzt.

Britischer Fabrikant von Hartgussrädern. . . [Seite 716.]

Die hier erwähnte Firma macht geltend, dass sie, was die Herstellung von Bahnwagenrädern aus Hartguss in Grossbritannien betrifft, bahnbrechend gewesen sei.

Gasmaschinen für elektrischen Bahndienst. . . [Seite 717.]

Die Beschreibung betrifft einen neuen Gasmaschinentypus zum Treiben elektrischer Stromerzeugungs-Maschinen ; gebaut werden sie von 10 bis zu 650 PS, mit zwei oder drei Cylindern je nach der Grösse. Der Durchschnitt der abgebildeten Maschine ist durch einen Cylinder einer mit 3 Cylindern ausgestatteten Maschine, bei der sämtliche Cylinder vollständig gleich sind, geführt. Die Maschine ist einfach wirkend, und jedes Piston erhält bei jedem zweiten Hub einen Stoss. Ehe das Gas durch Oeffnung M und das Ventil J einströmt, wird es mit Luft vermischt, wird durch einen elektrischen Funken an F entzündet und nachher durch das Ausblaseventil E und die Mündung O nach aussen geleitet. Das Verfahren zum Reguliren der Geschwindigkeit unterscheidet sich gänzlich von dem der meisten Gasmaschinenfabrikate, bei denen die Anzahl der Entladungen, je nachdem es die Kraft erfordert, verschieden ist. Bei der abgebildeten Maschine tritt bei jedem zweiten Hub in jedem Cylinder eine Entladung ein, doch richtet sich der Betrag des zugelassenen Gases nach den Erfordernissen der Belastung. Der Regulator, der zu diesem Zwecke vorhanden, ist auf einer Abbildung wiedergegeben. Diese Maschinen kommen bereits an einer 5 km langen Linie in Huntington, New York, zur Verwendung, wo sie zwei 37 kw-Dynamos treiben.

Geschichte einer bedeutenden deutschen Fabrikgesellschaft. [Seite 719.]

Es giebt dieser Artikel eine Darstellung der fortschreitenden Entwicklung der Allgemeinen Elektricitäts-Gesellschaft, die im Jahre 1882 gegründet und nunmehr ein Kapital von 47 Mill. Mark und einen Ueberschuss von 18 Mill. Mark aufweist; sie beschäftigt mehr als 12000 Arbeiter. Sämtliche Maschinenwerkzeuge in den Werken in Berlin werden direkt von elektrischen Motoren in Thätigkeit gesetzt. Den Strom liefert ein Maschinenhaus. Die Gesellschaft hat so viele Aufträge, dass die Werke Tag und Nacht im Gange sind. Besonders hervorgehoben wird die Drehstrom-Maschinerie der Gesellschaft, ein System, welches in den Werken für die Kraftvertheilung benutzt wird. Aus dieser Klasse Apparate hat die Gesellschaft eine besondere Spezialität gemacht.

Neuartiges System mit unterirdischer Stromzuführung und Oberflächenkontakt. . . . . . [Seite 721.]

Die Abbildung zeigt den Durchschnitt eines Kastens, der dazu dient, die Kontaktschienen todt zu halten, ausgenommen wenn der Wagen passirt. Die Stange an 4 wird von einer an dem Wagen angebrachten Kontaktvorrichtung zurückgestossen, was ein Umdrehen von Stange 3 zur Folge hat; dies wiederum bewirkt das Umdrehen von Scheibe 9 und stellt so die richtigen Kontakte her. Der Strom kann dann von der Strassenoberfläche oder von der regulären Untergrundleitung entnommen werden. Federn bringen die Theile in ihre ursprüngliche Lage zurück.

Vervollkommnung an elektrischen Bremsen. . [Seite 721.]

Die Bremse, die beschrieben wird, ist eine solche, welche aus einer gusseisernen Scheibe, die keilartig an der Wagenachse befestigt ist, sowie aus einem kreisförmigen elektromagnetischen Backen besteht, der so gehalten wird, dass er sich nicht drehen kann und durch Strom aus den Motoren, die als Generatoren arbeiten, gegen die Scheibe gepresst wird. Ein Diagramm ist beigefügt, welches die elektrischen Verbindungen des benutzten Kontrollers veranschaulicht.

Bedeutende Chicago'er technische Gesellschaft, die zugleich Kontrakte übernimmt. . . . . . [Seite 722.]

Luftbremsen. . . . . . [Seite 723.]

Einige Einzelheiten betreffs zweier Luftbremsetypen, die von einer bekannten Gesellschaft hergestellt werden, bilden den Gegenstand dieses Artikels. Bei jeder derselben wird der Luftkompressor von der Achse mit Hülfe von Zahnradübersetzung getrieben. Der Kompressor ist so eingerichtet, dass er nur dann arbeitet, wenn der Druck in dem Behälter unter eine bestimmte Grenze sinkt. Die Gesellschaft baut auch eine Luftbremse, die mit einem Motorkompressor, wie sie bereits in der April-Nummer beschrieben worden ist, benutzt wird. Illustrationen des obenerwähnten Kompressors sind beigegeben, ebenso solche des Betriebsventils auf der Plattform.

Neuer Typus eines Heizapparats. . . . . [Seite 724.]

Fig. 1 stellt einen elektrischen Heizapparat für Bahnwagen, deren Sitzplätze der Länge nach angeordnet sind, dar. Der Heizapparat ist aus zwei Spulen von unzerstörbarem Draht angefertigt, und sind dieselben an einer starken Asbestschnur, welche an den Enden an runden gerillten Porzellan-Isolatoren befestigt ist, aufgehängt. Die Schnur hält die Spulen an ihrem Platze, ohne jedoch dabei die Drähte irgendwie anzuspannen.

Instrument zum Messen von Elektrizität. . . [Seite 724.]

Die Abbildungen veranschaulichen ein Ampère- und Voltmeter, die von einem bedeutenden Fabrikanten in England unter Patenten, die Lord Kelvin bewilligt wurden, hergestellt werden. Derselbe Fabrikant verfertigt alle Arten von Messinstrumenten für Gleich- und Wechselströme.

Apparate zum Reinigen des Speisewassers sowie Heizapparate. [Seite 725.]

Man verwendet dieselben in Lokalitäten, wo Kalk oder sonstige feste Körper in dem Speisewasser enthalten sind; sie sollen dazu dienen, einen derartigen Stoff aus dem Wasser, ehe dasselbe in die Kessel gelangt auszuscheiden. Der Heizapparat, welcher beschrieben wird, ist ein offener Speisewasser-Heizapparat d.h. die Bestandtheile werden dadurch aus dem Wasser ausgeschieden, dass man das Wasser direkt der Thätigkeit des Dampfs aussetzt. Die Konstruktion des Heizapparats wird auf Fig. 1 veranschaulicht; derselbe besteht aus einer Reihe gekrümmter Pfannen, die aus Stahlplatten hergestellt sind. Wasser wird in die obere Pfanne geleitet, fliesst dann über den Rand in ein dünnes Gewebe ab und verbleibt an der Unterseite, bis der niedrigste Punkt erreicht ist, worauf es dann in die nächste Pfanne tröpfelt, und so weiter, bis es zur untersten Pfanne gelangt ist. Der Behälter, worin diese Pfannen sich befinden, wird mit Dampf angefüllt, und die in Auflösung versetzten Unreinigkeiten lagern sich auf der unteren Seite der Pfannen ab. Die Länge der letzteren beträgt ungefähr 1,8 m, und können dieselben behufs Reinigung leicht abgenommen werden. Fig. 2 illustrirt ein Werkzeug zum Bohren der Cylinder, welche die Pfannen halten.

Eine Sperrbremsenkurbel. . . . . . [Seite 725.]

Dieselbe ist, wie man aus der Abbildung ersehen kann, nur aus vier Stücken zusammengesetzt.

Neue, mit grosser Geschwindigkeit laufende Maschine. [Seite 726.]

Die betreffende Maschine ist eine englische Maschine des einfach wirkenden oder konstanten Drucktypus und mit zwei Cylindern nebst Kurbeln, die 180 Grad von einander liegen, oder drei Cylindern mit Kurbeln, die 120 Grad von einander plazirt sind, versehen. Die Abbildung stellt eine 250 pferdige Maschine dar, die mit einem Wechselstrom-Dynamo direkt gekuppelt ist.

Installirung einer grossen Akkumulatorenbatterie in Plymouth. [Seite 726.]

Dieselbe besteht aus 260 Zellen, die eine Leistungsfähigkeit von 120 Ampèren zu 480 Volt fünf Stunden lang zu entwickeln im Stande sind.

Ausblaseventile. . . . . . [Seite 726.]

Dieser Artikel enthält eine allgemeine und Profil-Ansicht eines Ausblaseventils für Kessel und Dampfröhren, und hat dasselbe bereits in hohem Grade Verbreitung gefunden. Die hauptsächlichsten charakteristischen Eigenschaften, welche die Profil-Abbildung wohl erkennen lässt, bestehen in einer besonderen Einrichtung, wodurch die Ansammlung von Kesselstein und Ablagerungen auf der Oberfläche der Scheibe im Ventil verhütet wird. Auch vermag man die Scheibe leicht umzukehren ; und kann man den Ventilsitz, wenn er abgenutzt ist, erneuern.

Langer Anhängewagen. . . . . . [Seite 727.]

Seiner ganzen Länge nach misst dieser Wagen 11,9 m. Er enthält zehn umwendbare und vier feststehende Sitze und weist Sitzplätze für siebenzig Personen auf. Der Wagen wiegt 8300 kg und ist auf Drehgestellen, von denen jedes nicht ganz 1810 kg wiegt, montirt.

Speisepumpen. . . . . . [Seite 727.]

Beschrieben wird eine Kesselspeisepumpe, die in Glasgow angefertigt ist und bei verschiedenen der grössten Ozeandampfer, sowie auch in vielen Kraftstationen zur Verwendung gelangt. Die Pumpe wird direkt von der Pistonstange getrieben, und ist kein todter Punkt vorhanden.

Oekonomische Krafterzeugung. . . . . [Seite 728.]

Der Ofen, welcher zum Verbrennen von Strassenkehricht — der hierbei als Heizmaterial dient — eingerichtet und in unseren Ausga-

ben für Mai und Juli 1898 beschrieben ist, hat seitdem eine bedeutende Verbreitung gefunden. Die Fabrikanten desselben stellen auch einen mechanischen Schürer dar, der, wie aus der veröffentlichten Probevornahme hervorgeht, ausgezeichnete Resultate liefert. Sie verfertigen ebenfalls eine Maschine, die dazu dient, um den Kohlensäuregehalt der von einem Ofen ausströmenden Gase zu bestimmen, indem auf diese Weise festgestellt wird, ob das richtige Luftquantum zu der Feuerbüchse zugelassen ist. Ein Verlust in Beziehung auf Sparsamkeit bildet die Folge, wenn zu viel oder zu wenig Luft bei der Verbrennung zur Verwendung kommt. Die Abbildung veranschaulicht eine derartige Vorrichtung.

Wagenbau-Werkstätten in Preston, England. . . [Seite 729.]

Gegenstand dieses Artikels, dem Abbildungen beigegeben, bildet die Beschreibung einer ausgedehnten Anlage, die vor Kurzem in England für den Bau von Wagen für Tram- und Kleinbahnzwecke fertig gestellt worden ist. Die Werke sind im Stande, jährlich 800 Drehgestellwagen gewöhnlicher Grösse zu fabriziren. Die gesamte Maschinerie wird durch elektrische Motoren, deren es 25 in den Werken giebt, getrieben. Die Kraft wird von einer Centralstation, die eine 225 pferdige Maschine nebst Dynamo enthält, erzeugt. Die Gesellschaft fertigt auch Untergestelle an, ist aber zugleich auch darauf eingerichtet, um Wagen, die mit irgend welchen Normal-Fabrikaten von Untergestellen ausgerüstet sind, liefern zu können. Die Abbildungen veranschaulichen einige der hauptsächlichsten Gebäude, sowie auch einige neuerdings gebaute Bahnwagen.

Automatische Schmierung. . . . . . [Seite 732.]

Dies bildet eine kurze Beschreibung eines, in St. Louis angewendeten, automatischen Schmierungssystems für Kraftstationen, Maschinen und Dynamos. Seit dessen Einführung hat man monatlich mehr als $300 (Mk. 1250) an Oelkosten und $150 (Mk. 625) an Arbeitskosten erspart. Das Oel wird mit Hülfe von Dampfpumpen nach den Trägern gepumpt, und erachtet man daher das Verfahren für wirksamer, als wenn man die Schwerkraft benutzte.

Frontlaternen für elektrische Bahnwagen. . . [Seite 732.]

Die Reflektoren dieser Frontlaternen sind gewellt und geben deshalb, wie man behauptet, ein intensiveres Licht.

Isolator für Leitungsschienen. . . . . [Seite 732.]

Derselbe besteht aus einem schmiedeeisernen Ständer, der zum Tragen eines Isolators bestimmt und worauf eine schmiedeeiserne Kappe montirt ist, welche die Leitungsschiene trägt. Diese Kappe hält die Schiene in horizontaler Richtung, gestattet jedoch einen kleinen Spielraum in vertikaler Richtung. Dadurch beabsichtigte man den Unannehmlichkeiten zu begegnen, die aus dem Brechen der Isolatoren entstanden, was früher stets deshalb passirte, weil die Schiene von den Isolatoren zu starr gehalten wurde.

Eine neue Dynamomaschine für Strassenbahnen. . [Seite 733.]

Zu den speziellen charakteristischen Eigenschaften dieser Dynamomaschine gehört das Verfahren, den Bürstenhalter in einer mit der Welle parallelen Richtung arbeiten zu lassen und das Bestreben der Bürsten, den Kommutator zu schneiden, aufzuheben; ferner das Entfernen der Polschuhe und Spulen, ohne das Joch oder den Anker ausser Ordnung zu bringen, und gründliche Ventilirung. Die Abbildung stellt eine Maschine von 800 kw für Oakland, Cal., dar.

Eine neue Verbindung aus Kupfer. . . . [Seite 733.]

Dieselbe besteht aus einem rechtwinkeligen Stück Kupfer von 76 mm Länge, 3 mm Dicke und 38 mm Höhe und wird innerhalb der Laschen mittelst Federn aus Stahl gegen die Schienen gepresst. Die Oberflächen sind amalgamirt.

Ausgedehnte Elektrizitäts-Werke in Chicago. . [Seite 734.]

Die Beschreibung betrifft die Werke der Siemens & Halske Gesellschaft in Amerika. Die Gesellschaft fabrizirt bis jetzt noch keine Bahnmotoren, baut jedoch sämtliche Arten Stromerzeugungs-Maschinen, einschliesslich Bahn-Dynamomaschinen in der Grösse bis zu 1500 kw, Motoren für Automobile, elektrische Bogenlampen, Wattmesser u. s. w. Das Muster der Bahn-Dynamomaschinen ist vor Kurzem geändert worden und auf der Abbildung vollständig wiedergegeben. Der Magnetrahmen ist aus Gusseisen, und sind die Polenden von besonderem Typus. Der Anker hat eine grosse Oberfläche und einen bedeutenden Durchmesser bei verhältnismässig geringer Tiefe. Dies gestattet eine gute Ventilirung mit einem unbedeutenden Spannungsunterschied zwischen den danebenliegenden Stromwenderstäben. Zahlreiche Luftleitungen laufen strahlenförmig durch den Anker. Die Speichen des Ankerrahmens sind so angeordnet, um Gebläseluft durch diese Kanäle senden zu können. Der Stromwender hat einen grossen Durchmesser, wiewohl er nicht ausserhalb der Ankerspulen und Felder, wie es gewöhnlich bei den ursprünglichen Maschinen von Siemens & Halske und den in Europa gebauten der Fall, plazirt ist. Die Bürstenhalter sind von einem besonderen Typus und dazu bestimmt, einen konstanten Druck der Bürsten gegen den Kommutator zu sichern. Die Herstellung von Motoren für Automobile ist eine Spezialität, und die Werke können wöchentlich 125 Motoren dieser Art anfertigen; dieselben besitzen eine Leistungsfähigkeit von 2 kw, sind indessen so eingerichtet, dass sie beständig zu 4 PS mit einer Steigung von mehr als 40 Grad C. laufen können. Die Gesellschaft baut auch sehr viele rotirende Umwandler.

Neue isolirende Klemmschraube. . . . . [Seite 737.]

Dieselbe kommt da zur Verwendung, wo zwei isolirte Drähte verbunden werden sollen. Die Enden der Drähte werden zunächst ihrer Isolirung entblösst, und schiebt man dann eine Messingmuffe über dieselben. Zwei durch die Muffe gehende Schrauben halten die Drähte fest. Die Muffe ist mit einem steifen Gummimantel und mit zwei weichen Gummikappen versehen, welche sodann aufgeschoben werden, so dass nun sämtliche Metalltheile vollständig isolirt sind. Die Verbindung der Drähte kann man dadurch aufheben, dass man die weichen Gummikappen abschiebt und dann die Schrauben lockert. Ganz speziell eignet sich diese Vorrichtung zur Herstellung der Verbindungen zwischen den aus Motorgehäusen herausragenden Drahtenden und denen an Wagen.

Momentausschalter. . . . . . [Seite 737.]

Ein solcher Ausschalter kann nicht geschlossen werden, ohne dass die Beschaffenheit des Kreisstroms normal ist, so dass demnach keine Gefahr für die Beschädigung der eingeschalteten oder in Betrieb befindlichen Apparate zu fürchten ist. Der Stromkreis öffnet sich sehr sorgfältig und das Entstehen von Lichtbogen wird auf ein Minimum beschränkt.

Abgangsdampf-Haube. . . . . . [Seite 737.]

In dieser Abgangsdampf-Haube wird das Wasser mittelst Centrifugalkraft von dem Dampf abgesondert.

Schöner Bahnwagen für Braintree, Massachusetts. . [Seite 738.]

Die Abbildung stellt einen mit 15 Bänken versehenen, offenen Bahnwagen dar, der sich auf elektrischen Sommerbahnen mit grossem Verkehr als sehr populär erwiesen hat. Derselbe hat eine Gesamtlänge von 12,9 m und eine Breite von 2,2 m. Die zweite Abbildung veranschaulicht ein neuartiges Untergestell, welches von denselben Fabrikanten gebaut wird. Es hat einen aussergewöhnlich kleinen Radstand und soll auf Bahnen, die Kurven mit kurzem Radius aufweisen, zur Verwendung kommen.

Bedeutende Chicago'er Glimmer-Gesellschaft. . [Seite 738.]

Bezug genommen ist hierbei auf eine Gesellschaft, die den ausgedehntesten Handel mit Glimmer in Amerika für sich in Anspruch nimmt.

Seife zum Wagenreinigen. . . . . , . [Seite 739.]

Die Beschreibung betrifft eine besondere Seife, die zum Wagenreinigen dient und von sehr vielen Dampfbahnen und Strassenbahngesellschaften Amerika's verwendet wird. Die Erfahrung hat diese Gesellschaften darüber belehrt, dass ein häufiges Reinigen sowohl die Farbe wie auch den Lack an den Wagen schützt, dass aber Wasser mit gewöhnlicher Seife nicht zweckentsprechend ist. Eine Anzahl Gesellschaften reinigen Wagen zweimal die Woche mit diesem Stoff, dagegen hält man an anderen Bahnen ein einmaliges Reinigen wöchentlich für hinreichend.

Toledo-Fremont & Norwalk'er elektrische Bahn. . [Seite 740.]

Die Länge dieser Bahn, die jetzt im Bau begriffen ist, beträgt 100 km. Die Kraftvertheilung geschieht mittelst des Dreiphasensystems zu 15000 Volt, die behufs Benutzung auf der Bahnstrecke in Gleichstrom umgewandelt werden.

Ein neues Unternehmen in Deutschland. . . [Seite 740.]

Die Firma, um die es sich hier handelt, hat die Agentur eines bekannten Fabrikanten von Wagenkasten übernommen. Die Wagenkasten werden nach Deutschland gesandt und dort an Ort und Stelle zusammengesetzt. Bestellungen auf Wagen dieser Art für Berlin sind erst vor Kurzem eingetroffen. Dieselbe Firma liefert auch Untergestelle und Luftbremsen.

Maschine zum Aufreissen alter Schienen. . . [Seite 740.]

Eine solche Maschine kann ungefähr 3 km Gleis pro Tag aufreissen, bricht auch die Schienen in jede Länge, gewöhnlich in Längen von 1,2 m bis 2,4 m. Die auf der Abbildung dargestellte Schiene ist 150 mm hoch, doch ist die Maschine im Stande 225 mm hohe Schienen zu zerbrechen.

Drehgestell No. 14 B-3. . . . . . [Seite 741.]

Der Radstand dieses Drehgestells beträgt nur 1,22 m; es ist deshalb dazu bestimmt, bei Bahnen mit scharfen Kurven zur Verwendung zu kommen. Der Wagen hat ein mit Federung versehenes Kissen. Die Motoren werden aussen an den Achsen, anstatt zwischen denselben, mitgeführt, und die Bremsvorrichtung liegt zwischen den Achsen.

Trolleyruthenhalter mit Sperrung nebst Haspel. . [Seite 742.]

Die betreffende Vorrichtung dient dazu, um die Trolleyruthe zu verhindern, eine vertikale Richtung anzunehmen, im Falle die Rolle entgleisen sollte.

Atlas-Schienenstoss. . . . . . [Seite 742.]

Dieser Stoss ist in Amerika in ausgedehntem Maasse adoptirt, und sind zwei Arten desselben durch Abbildungen veranschaulicht.

Automatisches Sicherheits-Absperrventil. . . [Seite 742.]

Dasselbe ist dazu bestimmt, in die zwischen den Kesseln und Maschinen befindliche Hauptdampfröhre eingestellt zu werden und eine automatische Schliessung zu veranlassen, sobald ein Bruch in der Hauptröhre oder an der Maschine vorkommt, der zu einer leichten Verminderung des Dampfdrucks Anlass geben kann. Die Konstruktion erhellt aus der Abbildung, welche die Vorrichtung im Profil darstellt.

Rollenträger für Strassenbahnwagen. . . . [Seite 743.]

Die Träger für eine Achse werden sämtlich in einem Gehäuse gehalten, welches die Enden verbindet, so dass man sie herausheben und zu irgend einer Zeit wieder einsetzen kann. Die Rollen selbst haben eine gehärtete und geglättete Stahloberfläche. Die Gesellschaft garantirt eine Ersparnis von 10 bis 15 Prozent an der Kraft, die gebraucht wird.

Hydraulischer Schieber-Regulator. . . . [Seite 743.]

Diese Vorrichtung öffnet und schliesst den Schieber je nach dem Drucke in den Kesseln, wodurch der Kesseldruck konstant gehalten wird.

Oelfilter. . . . . . [Seite 743.]

Derselbe weist einige charakteristische Neuheiten auf und enthält auch eine Scheidevorrichtung, wodurch das überschüssige Oel und Wasser von der Kolbenstange, wie auch das, welches aus Ventilen läuft, abgesondert wird. Das Oel leitet man dann nach einer Raffinirkammer, wo es erhitzt und geklärt wird, und lässt es weiterhin durch Baumwollenabgang laufen, ein Prozess, durch den leichtere Unreinigkeiten ausgeschieden werden. Jeder Filter ist mit einem starken Vergrösserungsglase ausgestattet, so dass man damit das gereinigte Oel genau untersuchen kann.

Automatische Wagenkuppelungen. . . . . [Seite 744.]

Die Illustrationen veranschaulichen zwei Arten einer Wagenkuppelung, wie sie thatsächlich bei allen Hochbahnen in Amerika und vielen Bahnen auf der Strassenoberfläche zur Verwendung kommt. Mehr als 50000 sind gegenwärtig in Gebrauch. Diese Kuppelungsvorrichtungen werden auch in vielen europäischen Städten benutzt.

Kohlenkonveyor in Washington. . . . . [Seite 744.]

Diese Abbildung giebt eine Ansicht von dem Konveyor, wobei die Asche aus den Kesseln genommen und nach dem Aschenbehälter befördert wird. Der Tunnel ist ungefähr 61 m lang. Derselbe Kübel befördert die Kohlen nach den Kesseln.

Neu errichtete Fabrik für Luftbremsen. . . [Seite 747.]

Beschrieben wird die neue Fabrik einer Gesellschaft, die durch ihre Herstellung von Luftbremsen für Strassenbahnen bedeutenden Umsatz erzielt. Die ganze Kraft wird mittelst Elektricität oder komprimirter Luft durch die Fabrik vertheilt.

Bedeutende Drahtproducenten. . . . . [Seite 747.]

Die in Betracht kommende Gesellschaft erhebt Anspruch darauf, die umfangreichste individuelle Anlage, die existirt, was sowohl die Herstellung von elektrischen Leitungen wie auch von Drahtseil betrifft, zu besitzen. Alle Arten Drähte werden angefertigt.

Eine bedeutende britische Lieferungs-Firma. . . [Seite 748.]

Die betreffende Firma ist i. J. 1800 gegründet worden und führt alle Arten Messinstrumente, wobei sie aus Registrir-Instrumenten, wie sie in England von der Handelskammer vorgeschrieben sind, eine Spezialität macht.

Aufgespeicherte Luft zum Bremsen von Bahnwagen. [Seite 748.]

Bei diesem System wird die Luft in der Kraftstation ungefähr zu fünfzehn Atmosphären komprimirt und dann in Behältern auf den Wagen aufgespeichert. Vor ihrer Wirkung auf die Bremsen muss sie ein Reduktionsventil passiren, welches den Druck ungefähr auf drei Atmosphären reduzirt. Auf dem Wagen wird kein Kompressor mitgeführt. Die Gesellschaft, die ca. vor einem Jahre gegründet wurde, hat bereits gegen 42 Wagen mit befriedigenden Resultaten damit ausgerüstet und macht für diese Bremsen eine Reihe von Vorzügen geltend.

Neues Elektrizätswerk in England. . . . [Seite 749.]

Es beschreibt dies das Werk eines wohlbekannten Händlers mit elektrischen Bahnapparaten.

Table des Matières—Octobre, 1899.

Opération pratique des tramways en Amérique, en prenant Chicago pour example. . . . . . [Page 613.]

Le système des tramways à niveau de Chicago est opéré par dix compagnies indépendantes et le système de chemin de fer élevé par cinq compagnies. Plusieurs des lignes principales sont encore opérées par le système du cable ; mais la plus grande longueur des lignes est actuellement opérée par l'électricité, et on a l'intention de changer, le plutôt possible, le système du cable pour le système électrique. Les tramways à chevaux ont presque disparu de Chicago et ne se composent plus que de quelques lignes d'alimentation pour les lignes à cables. Les chemins de fer élevés sont tous opérés par l'électricité, formant un système de chemins de fer élevés opérés par l'électricité, de beaucoup le plus considérable qui existe dans le monde entier. Il y a naturellement à Chicago un grand nombre de stations de force motice pour alimenter ces propriétés indépendantes et, de presque toutes, nous donnons des illustrations qui montrent l'arrangement des machines, etc. Ces stations sont aussi représentées par un diagramme à échelle de telle sorte qu'un coup d'oeil suffit pour réaliser leurs dimensions relatives. Presque toutes les stations importantes sont sans condenseur, seulement trois ou quatre stations en étant pourvu. L'impossibilité d'obtenir une quantité suffisante d'eau à un prix raisonable a amené l'usage de tours et de tables à refroidir, au moyen desquelles l'eau pour la condensation est usée plusieurs fois. Les voies de Chicago, bien que n'étant pas particulièrement admirables, sont cependant dignes d'attention, surtout en ce qui regarde l'assemblage à la fonte des joints; assemblage qui a atteint là-bas un haut degré de perfection. La construction aérienne est très bonne quoique simple et l'on s'est efforcé non pas d'obtenir des effets d'ornementation mais bien le moins d'obstruction possible aux rues. Uue description des méthodes de construction employées sur le Northwestern Elevated accompagnée d'illustrations conclut cet article.

Opération pratique des tramways en Allemagne. Par Louis J. Magee. . . . . [Page 647.]

Cet article contient une description très valuable de l'opération allemande par le directeur administrateur de l'Union Elektricitäts Gesellschaft, l'une de plus grandes compagnies manufacturières de l'Allemagne. La propiété des tramways en Allemagne fait l'objet d'une longue discussion. La relation des grands syndicats, ou groupes financiers, à l'industrie des tramways est mise en avant et on peut difficilement évaluer trop haut l'influence qu'ont eu ces syndicats sur le développement rapide de l'Allemagne industrielle. La particularité principale de l'opération des tramways en Allemagne, qui la distingue de ce qui se passe en Amérique, est l'usage d'un mélange de tractions électriques. Les voitures sont opérées avec des accumulateurs dans le centre des villes et au moyen de fils de trolleys dans les faubourgs. Une autre chose faite en Allemagne à l'exclusion de l'Amérique et de tout autre pays est la construction de poteaux d'ornement servant à la fois au support des fils de trolleys, à l'éclairage, etc, M. Magee décrit d'une manière très intéressante les détails de coutume allemande en ce qui concerne les stations de force motrice, les voies, les constructions aériennes, le matériel roulant, etc. Il est évident que l'Allemagne a porté l'art de l'ingénieur pour tramways électriques au point le plus élevé de développement.

Opérations pratiques des tramways électriques dans la Grande Bretagne. Par Sidney H. Short. . . . [Page 663.]

Le professeur Short a aggloméré dans cet article la plupart des particularités principales de l'opération pratique anglaise. Il explique les difficultés qui ont accompagné jusqu'ici, dans ce pays, le développement de cette industrie. Difficultés dues aux restrictions imposées par l'action parlementaire et par le désir grandissant de possession municipale à l'encontre d'entreprises privées. Les détails techniques de construction des voies, des lignes aériennes, du matériel roulant, sont donnés avec beaucoup de soins et accompagnés de nombreuses illustrations.

Caractère financier des grands systèmes de tramways du monde entier. Par Edward E. Higgins. . . . [Page 680.]

Cet article est une compilation des statistiques du métrage kilométrique, du capital engagé, des recettes et des dépenses des systèmes de tramways dans les villes de plus de 500000 habitants de tous les pays du monde. Cette compilation est arrangée de manière à montrer les profits comparés et les oportunités pour les placement des capitaux.

Opération pratique des tramways électriques dans l'Autriche-Hongrie. Par E. A. Ziffer. . . . . [Page 685.]

Le premier railway électrique établi, en Autriche, pour le transport des voyageurs fut inauguré en 1883. Il avait 4 km. de long. Le premier railway électrique de Hongrie date de 1889. Il était construit d'après le système du conduit souterrain. Une gravure montre ce conduit. On s'en sert beaucoup à Budapest et on l'installe à présent à Vienne. Le système du trolley est cependant d'un usage général. Des concessions sont octroyées par le gouvernement à des compagnies particulières, mais la durée de ces concessions est limitée à 60 ans. Les municipalités ont, elles aussi, le droit de construire et d'opérer des tramways. Tous les chemins de fer d'une importance secondaire sont exempts des impôts gouvernmentaux pour une période de vingt ans, dans quelques cas ils sont aussi exempts d'impôts municipaux. L'auteur donne une liste des railways électriques, avec leur longueur moyenne, la largeur de la voie, le nombre de voyageurs transportés et les recettes. Les rails dans les villes sont posés sur une couche, soit de béton soit de pierre concassée, d'une épaisseur de 30 cm., leur poids varie de 34 à 43 kg. par m. En dehors des limites des villes on se sert de rails Vignole, d'un poids variant entre 21 et 23,5 kg. par m., posés sur des traverses de bois ou de métal. L'auteur continue en décrivant les différents manières d'assemblage de rails, de fils d'alimentation et de poteaux. Le fil du trolley est généralement fait en cuivre dur, étiré, d'un diamètre variant de 7 à 8,25 mm. Le Baden-Böslau use un fil de silicon-bronze de 7 mm. de diamètre. Dans quelques cas le dessus du fil de trolley est couvert d'un protecteur en bois, tenu en place par des emboîtures métalliques, qui a pour but d'empêcher des fils de téléphones ou de télégraphe, brisés, d'établir un contact. La

voiture la plus employée est la voiture du soit-disant Hambourg type, avec une longue plateforme à chaque extrémité et de la place pour 20 passagers assis. La longueur totale est de 8,4 m. Dans les petites villes la longueur totale des voitures varie entre 5,8 et 7 m. L'auteur suit avec une description des différents types de réceptacles pour courant ou trolley. La vitesse est toujours prescripte par les autorités, elle est généralement de 15 km. à l'heure. Elle peut être portée à 18 km. dans les rues où la circulation n'est pas considérable, mais elle doit être réduite à 10 km. dans les rues étroites ou très prises par la circulation. Dans les faubourgs une vitesse de 25 à 30 km. par heure est permise. La plupart des stations de force motrice opèrent des condenseurs et emploient des unités directes. Les chaudières sont du type tubulaire et la consommation de charbon par kw.-heure varie entre 0,8 et 0,5 kg. On se sert quelquefois d'économiseurs, et toujours de chaudières pour eau d'alimentation. L'auteur conclut par une courte description de lignes industrielles et minières.

Opération pratique des tramways dans la République Argentine. Par E. Manville. . . . . [Page 693.]

M. Manville, un membre de la maison d'ingénieurs bien connus, Kincaid, Waller & Manville, de Londres, qui ont été retenus comme ingénieurs pour la construction de certains tramways à Buenos Ayres, décrit les conditions sous lesquelles on obtient des concessions de tramways dans la République Argentine et aussi les problèmes physiques et autres que l'on a à surmonter. Les autorités éprouvent une répugnance considérable à octroyer des concessions de longue durée et les compagnies sont complètement sous le contrôle des municipalités qui imposent une taxe de six pour cent sur les recettes brutes pour l'entretien du pavé des rues où passent les tramways et imposent aux compagnies d'autres charges qui sont lourdes sans êtres prohibitives. On se sert de trois sortes de voies à Buenos Ayres, suivant la circulation. Dans l'une, les rails sont supportés par une base toute en béton, dans l'autre le béton n'existe que le long des rails, et dans la troisième les rails sont simplement fixés sur des traverses sans béton. Dans le système de distribution, la forme maxima de potentiel permis est très petite. On obtient ce résultat par l'emploi de dynamos auxiliaires négatives tandis que les feeders positifs conduisant aux extrémités du système sont munis de dynamos positives. La construction aérienne et le système de feeders souterrains sont excellents dans la République Argentine et le matériel roulant est bon. La force motrice est obtenue principalement des stations locales de force motrice dont plusieurs fonctionnent sur une grande échelle.

Les actions de moteurs de railways. Par W. B. Potter. [Page 701.]

L'auteur est l'ingénieur en chef de la division des railways de la General Electric Company. Il constate que la force en chevaux des moteurs construits par la compagnie est évaluée d'après un étalon arbitraire, basé sur l'élevation temporaire de la température du moteur de 75 degrés centigrades pendant une heure et sous chargement complet, la température de l'air environnant étant supposée être 25 degrés centigrades. Le moteur ne peut pas être opéré à ce train de rendement continuellement, mais on peut l'opérer pour de courtes durées et sans le déteriorer à un train plus élevé. La force en chevaux moyenne supportée par un moteur pendant une journée ne devrait pas dépasser 30 pour cent de son évaluation obtenue comme ci-dessus. Quand des freins électriques sont en usage le moteur devrait avoir une capacité de 20 à 25 pour cent plus grande que quand ils ne sont pas en usage. Dans des conditions ordinaires de ville la force en chevaux requise dans les moteurs devrait être le poids total en tonnes multiplié par la vitesse maxima, en miles, et par heure sur une surface à niveau, le tout divisé par 5. Si la vitesse maxima n'est pas connue on peut la considérer double celle de l'horaire. Cette règle devrait, cependant, être appliquée avec précaution; elle indique seulement la capacité minima sous des conditions ordinaires. Dans le service ordinaire des rues l'effort de traction pendant l'accélération est d'entre 10 et 15 pour cent du poids charié. Dans le service élevé ou suburbain il est généralement de 5 à 7½ pour cent, tandis que dans le transport des marchandises où la vitesse est réduite, il peut ne pas exéder 1½ ou 2 pour cent. Dans le service ordinaire le poids sur les roues de support devrait être au moins six fois l'effort de traction nécessaire. La capacité approximative d'une station de force motrice pour n'importe quel service est d'environ 100 watts heures par tonne mile avec des vitesses ordinaires.

Système électro-pneumatique pour contrôler les moteurs de railways et autres. . . . . . [Page 703.]

Ce système est en usage à Pittsburgh et à Wilmerding où l'on forme des trains de deux ou plusieurs voitures à moteurs. Comme chaque voiture a son contrôleur, il est nécessaire que tous ces contrôleurs soient opérés en exact synchronisme de manière à ce que tous les moteurs aillent à la même vitesse. L'opération de tous les contrôleurs est dirigée de la plateforme de devant de la première voiture et est accomplie par l'air comprimé. Au dessus de chaque contrôleur sont deux cylindres dont l'un renferme une tige à pignon qui s'engage dans une roue dentée sur le dessus du contrôleur. Les cylindres à air sont opérés en unisson par une petite batterie électrique manoeuvrée par un petit commutateur électrique dans le premier vestibule. Le seconde cylindre à air sert à ramener le contrôleur à la position O, et est aussi opéré par le motorman de la première plateforme. L'interrupteur du circuit est arrangé de manière à fermer les contrôleurs dans le cas où il s'ouvrirait. Si les freins électriques sont appliqués, tous les contrôleurs sont automatiquement fermés. L'appareil à comprimer l'air, dont nous donnons une illustration, est aussi d'un nouveau type. Il consiste d'une pompe compound rotative opérée directement par un petit moteur. Dans les trucks en service, les ressorts qui supportent les moteurs sont entièrement distincts de ceux qui supportent la voiture.

Un grand manufacturier de matériel électrique. . [Page 708.]

Il fait une spécialité de la manufacture de fils métalliques et de joints de rails.

Appareils pour transmission de la force motrice à New York. [Page 709.]

Cet article donne la description des générateurs de courant alternatif, des convertisseurs rotatifs et des transformateurs dont se servira le Metropolitan Street Railway de New York. Les générateurs sont du système à inducteur mobile, avec des armatures extérieures stationaires. Chaque machine a une capacité de 2500 kw. et produira du courant trois-phasé de 6600 volts, avec une fréquence de 25 cycles par seconde et marchant à la vitesse de 75 révolutions par minute. L'inducteur a 40 pôles, et est monté directement sur l'axe de la machine. Il est bien ventilé. Chaque bobine est essayée avec un courant alternatif de 25000 volts. L'armature fixe est en fer fondu et munie de plaques de fondation glissantes de manière à pouvoir être poussée de côté, en dehors de l'inducteur ce qui permet un libre accés, pour inspection et réparations, soit à l'armature soit à l'inducteur. Ce dernier est composé d'un anneau d'acier fermement bouloné à un cadre de fer fondu qui est fixé par une clef à l'axe de la machine. Les transformateurs aux stations de convertisseurs rotatifs sont de 250 kw. chacun et il en faut trois pour opérer chacun des convertisseurs rotatifs. L'enroulement primaire du transformateur est désigné pour 600 volts, et le secondaire pour 350 volts. Les transformateurs sont refroidis par un appel d'air qui les traverse; ils ont à chargement complet, une efficacité de 98,22 pour cent. Les convertisseurs rotatifs sont de 990 kw. chacun et opèrent à 214 révolutions par minute. L'inducteur a dix huit pôles en fer fondu. L'enroulement de l'armature est en barres de cuivre. Les brosses sur l'éxtrémité alternative du convertisseur rotatif sont en cuivre et ce convertisseur rotatif opère comme une machine six-phasé. Les convertisseurs rotatifs sont mis en mouvement avec un courant direct au moyen du courant fourni par une batterie d'accumulateurs.

Nouveau type de machine compound. . . . [Page 711.]

Le point nouveau essentiel de cette machine consiste dans la méthode d'opérer les soupapes d'admission aux cylindres de basse pression. Ces soupapes sont opérées en partie par un excentrique fixé sur l'axe de la machine et en partie par le même excentrique qui opère les soupapes du cylindre de haute pression. Ces dernières oupapes sont naturellement contrôlées par le gouverneur. On prétend que cette manière d'opérer les soupapes de basse pression, supprime les inconvénients provenant de l'opération exclusive par un excentrique fixe sur l'axe de la machine ou exactement en unisson avec les soupapes de haute pression.

Accumulateurs pour traction. . . . . . [Page 712.]

C'est la description d'un accumulateur anglais bien connu. Les plaques sont formées par le procédé Planté, avec de l'acide sulphurique seulement, et durent à peu près 6 semaines. Les plaques sont toutes jointes à une longue barre sans vis. On n'emploie sur le côté des piles pas d'autre matériel que du verre et du plomb et les batteries sont maintenues, sous une guarantie, à un prix variant entre 3 et 6 pour cent de leur coût. On se sert beaucoup de ces accumulateurs en Grande Bretagne et ailleurs comme régulateurs pour les stations de force motrice.

Nouveau type de moteurs pour tramways. . . [Page 713.]

Cet article donne la description de cinq types de moteurs récemment mis en vente par la même compagnie et qui varient en dimensions depuis 30 chevaux jusqu'à 150 chevaux. Les deux premiers moteurs décrits (Nos. 68 et 69) sont arrangés de telle sorte qu'en enlevant 4 boulons et séparant les ressorts qui le suspendent, le moteur entier peut être enlevé du dessous de la voiture par un cric à vis placé dans la fosse. Une voiture équippée avec ces moteurs en change généralement tous les deux jours, ce qui permet une inspection soigneuse. Ces moteurs sont arrangés pour lubrification soit par la graisse, soit par l'huile, et l'huile est versée entre les roues dentées, là ou la pression est la moindre. Le troisième moteur (No. 56) est distiné à être inspecté étant sur la voiture et à n'être pas souvent enlevé. Il est composé de deux parties réunies au centre par des charnières et par dévissant un boulon la partie inférieure peut être ouverte dans la fosse, tandis que l'armature peut rester dans la partie supérieure ou inférieure, à volonté. Le quatrième moteur (No. 70) et le cinquième moteur (No. 50 C) sont destinés à de gros travaux et sont respectivement de 110 et de 150 chevaux. Ils sont destinés à être montés sur des trucks que l'on peut faire rouler de dessous la voiture et on enlève alors la partie supérieure du moteur. Tous les moteurs sont à l'épreuve de la poussière et de l'eau et sont pourvus de barres polaires laminées, au lieu d'être fondues, dans l'empiècement.

Joints de rails. Par W. F. Ellis, C. E. . . . [Page 715.]

L'ancienne forme d'assemblage au moyen de plaques allongées se voit dans les Figs. 2 et 3. Ceci a été amélioré dans la construction ordinaire des voies par la forme que montrent les Figs. 1 et 4. L'auteur ne considère aucune de ces formes recommandables. Parmi d'autres raisons il montre par la Fig. 4 que le rail coupe la traverse ce qui cause la plaque allongée à forcer sur les boulons. Les Figs. 5 et 6 montrent des embarras occasionés par les plaques allongées ordinaires quand les trous ne sont pas exactement percés. Comme remède l'auteur recommande le joint que montrent les Figs. 7 et 8 appliqué à un rail Vignole. La Fig. 9 montre le joint ordinaire appliqué au rail modèle américain et la Fig. 10 le joint perfectionné appliqué au même rail.

Nouvelle fabrique de charbon. . . . . . [Page 716.]

C'est la description d'une nouvelle fabrique qui va entreprendre la manufacture de brosses de charbon. Elle est située dans la région charbonnière de la Pennsylvanie et on emploiera beaucoup le gaz naturel pour chauffer les fours et autres usages.

Marches non glissantes pour voitures. . . . [Page 716.]

Ces marches sont faites d'acier côtelé avec du plomb fondu coulé dans les rainures. On s'en sert beaucoup comme marchepieds de voitures et aussi sur les escaliers des stations de chemins de fer élevés.

Manufacture anglaise de roues en fer trempé. . [Page 716.]

La maison dont s'occupe cet article prétend être l'innovatrice, en Angleterre, de la manufacture de roues en fer trempé.

Machines à gaz pour service de railways électriques. [Page 717.]

Cet article décrit un nouveau type de machine à gaz pour opérer des générateurs électriques, de 10 à 650 chevaux, avec deux ou trois cylindres suivant leur dimension. La section de la machine dont la gravure est ci-jointe est la coupe d'un cylindre d'une machine à trois cylindres, tous ces trois cylindres étant absolument pareils. La machine est à simple action, et chaque piston reçoit une impulsion une fois sur deux. Le gaz est mélangé à l'air avant son admission au cylindre par l'ouverture M et la soupape J. Le gaz est enflammé par une étincelle électrique à F, et est ensuite chassé à travers la soupape de sortie E et la décharge O. La méthode employée pour gouverner la vitesse est entièrement différente de celle de la plupart des autres marques de machines à gaz, en ce que le nombre des explosions est varié suivant les besoins de la force motrice. Dans la machine dont nous donnons l'illustration une explosion est produite dans chaque cylindre à chaque second coup de piston, mais la quantité de gaz employé varie suivant les besoins du chargement. Le gouverneur qui permet d'obtenir ce résultat est l'objet d'une illustration. Ces machines ont été en usage sur une ligne de 5 km. de lougueur à Huntington, Etat de New York où elles opéraient deux générateurs de 35 kw.

L'histoire d'une importante compagnie manufacturière allemande. [Page 719.]

Cet article décrit les progrès de l'Allegemeine Elektricitäts Gesellschaft, qui fut organisée en 1882 et a maintenant un capital de 47 millions de marks, un surplus de 18 millions de marks et emploie plus de 12000 ouvriers. Tous les outils dans les usines, à Berlin, sont opérés directement par des moteurs électriques. Le courant est fourni par une station de force motrice. Cette compagnie a tellement de commandes que les usines marchent nuit et jour. Une mention spéciale est faite de la machinerie trois-phasé de la compagnie, et c'est ce système qui est employé pour distribuer la force motrice dans les usines. La compagnie s'est fait une spécialité de ce genre d'appareils.

Amélioration des freins électriques. . . . . [Page 721.]

Le frein décrit consiste en un disque de fer fondu fixé par une clef à l'essieu de la voiture, et d'un sabot circulaire électro magnétique, tenu de telle manière qu'il ne puisse pas tourner. Il est pressé contre le disque par un courant venant des moteurs qui agissent comme générateurs. Nous donnons un diagramme montrant les communications électriques du contrôleur dont on se sert.

Nouveau type d'un système à conduit et à contact de surface. [Page 721.]

La gravure montre une coupe d'une boite destinée à tenir les rails de contact dépourvus de courant, excepté au passage des voitures. La barre 4 est poussée en arrière par un appareil de contact qui se trouve sur la voiture. Ceci fait tourner la barre 3 qui en entraînant le disque 9 produit les contacts nécessaires. Le courant peut alors être pris soit de la surface de la rue soit du conduit régulier. Des ressorts renvoient toutes ces parties à leur première position.

Freins à air comprimé. . . . . . [Page 723.]

Cet article donne quelques détails sur deux types de freins à air comprimé faits par une compagnie bien connue. Dans chacun de ces freins la machine à comprimer l'air est actionnée par l'essieu au moyen de roues dentées. La machine à comprimer est arrangée de telle sorte qu'elle ne fonctionne que lorsque la pression dans le réservoir tombe au dessous d'une certaine limite. La même compagnie construit aussi un frein à air pour service avec une machine à comprimer à moteur décrite dans notre numéro d'Avril. Nous donnons des vues de la première de ces deux machines à comprimer et aussi de la soupape d'opération qui se trouve sur la plateforme. Cette soupape comporte une mesure de pression.

Instruments pour mesures électriques. . . . [Page 724.]

Les gravures montrent un ampèremètre et un voltmètre fait par un important manufacturier d'Angleterre d'après des brevets pris par Lord Kelvin. Le même manufacturier fait aussi toutes sortes d'intruments de mesures pour courants directs ou alternatifs.

Nouveau type de machine à chauffer les voitures. . [Page 724.]

La Fig. 1 montre un chauffeur électrique pour des voitures à sièges longitudinaux. Ce chauffeur est fait de deux bobines de fil non-corrosif suspendues à une forte corde d'asbestos (B) attachée par ses extrémités à des isolateurs de porcelaine ronds et évidés (D.) La corde tient les bobines en place sans occasioner de tension au fil.

Une poignée de freins à roue dentée. . . . [Page 725.]

Cette poignée, comme le montre la gravure, n'est composée que de 4 pièces.

Appareils pour purifier et chauffer l'eau d'alimentation. [Page 725.]

Ces appareils sont en usage dans les endroits où l'eau d'alimentation contient de la chaux et autres solides: ils ont pour but de débarasser l'eau de ces produit avant son introduction dans les chaudières. L'appareil dont cet article donne la description est un appareil ouvert pour chauffer l'eau d'alimentation, c'est à dire que l'expulsion des corps étrangers a lieu par l'exposition directe, à l'action de la vapeur, de l'eau qui les contient. La Fig. 1 montre la manière dont cet appareil est construit. Il consiste en une série de bassins en plaque d'acier. L'eau entre dans le bassin supérieur et coule le long des bords en une mince couche adhérant au dessous jusqu'à ce qu'elle atteigne le point le plus bas d'où elle tombe dans le bassin suivant et ainsi de suite jusqu'au fond de la série des bassins. Le réceptacle qui contient ces bassins est rempli de vapeur et les impuretés conteues en solution dans l'eau sont déposées sur le dessous des bassins. Ceux-ci ont une longueur d'environ 1,8 m et peuvent facilement s'enlever pour le nettoyage. La Fig. 2 donne l'illustration d'un outil servant à percer les cylindres qui tiennent les bassins.

Soupapes d'échappement. . . . . . [Page 726.]

Cet article contient une vue générale et une coupe d'une soupape d'échappement pour chaudières et tuyaux à vapeur, qui a obtenu une proéminence considérable. Les points principaux se voient dans l'illustration de la coupe et consistent en un arrangement qui empêche le dépôt d'écaille et de sédiment de se produire sur le haut du disque de la soupape. Le disque peut aussi se renverser facilement et la base de la soupape peut être changée lorsqu'elle est usée.

Nouvelles machines à grande vitesse. . . . [Page 726.]

Ces machines sont de marque anglaise et du type connu comme machines à action unique ou constante Elles sont arrangées avec deux manivelles de cylindre écartées à 180 degrés ou avec trois cylindres aux manivelles écartées de 120 degrés. L'illustration montre une machine de 250 chevaux accouplée directement à un générateur à courant alternatif.

Grande installation d'accumulateurs à Plymouth. . Page 726.]

Cette installation consiste de 260 piles produisant pendant cinq heures 120 ampères à 480 volts.

Longue voiture sans moteur. . . . . . [Page 727.]

Cette voiture a 11,9 m de longueur totale. Elle contient 10 sièges à dossiers réversibles et quatre sièges fixes: 70 passagers peuvent s'y asseoir. La voiture pèse 8300 kg. et est montée sur des double trucks qui pèsent chacun moins de 1810 kg.

Pompes d'alimentation. . . . . . [Page 727.]

Cet article décrit une pompe d'alimentation pour chaudière manufacturée à Glasgow et qui est en service sur un grand nombre de paquebots et dans de nombreuses stations de force motrice. La pompe est manoeuvrée directement par la tige de piston et il n'y a pas de point mort.

Economique production de force motrice. . . [Page 728.]

La fournaise construite pour brûler les ordures comme combustible, et, que nous avons décrite dans nos numéros du Mai et de Juillet 1898, a depuis lors été employée d'une manière étendue. Les manufacturiers de cette fournaise font aussi un chauffeur mécanique que

donne d'excellents résuitats comme le montre l'essai dont nons publions le résultat. Ils fabriquent aussi une machine pour déterminer la quantité d'acide carbonique et le gaz échappant de la fournaise, ce qui indique si la quantité convenable d'air a été admise dans la chambre de chauffe. Une perte d'économie se produit si trop ou trop peu d'air est usé dans la combustion. L'illustration montre cet appareil.

Usines pour la construction de voitures à Preston, Angleterre. [Page 729.]

Cet article donne des vues et une description d'une grande usine récemment completée pour la construction en Angleterre de voitures de tramways et de légers wagons. Cette usine peut produire par an 800 voitures de dimensions ordinaires à double trucks. Toute la machinerie y est opérée par des moteurs électriques qui sont au nombre de 25 dans l'usine. La force motrice est produite dans une station centrale qui contient une machine et générateur de 325 chevaux. La compagnie manufacture aussi des trucks, mais est néanmoins préparée à fournir des voitures pourvues de trucks de n'importe quelle marque connue. Nous donnons des vues de quelques uns des bâtiments principaux et de voitures construites récemment.

Isolateur pour troisième rail. . . . . . [Page 732.]

Cet appareil consiste d'un rail de fer malléable destiné à porter un isolateur sur lequel est monté un couronnement de fer qui supporte le troisième rail. Ce couronnement tient le rail dans un alignement horizontal tout en lui permettant un léger jeu vertical. Le but de cet appareil est d'obvier aux inconvénients qu'occasionnait la casse d'isolateurs. Cette casse se produisait auparavant parceque le rail était tenu en place d'une manière trop rigide par les isolateurs.

Lanternes d'avant pour tramways électriques. . [Page 732.]

Les réflecteurs pour ces lanternes sont à surface zinguée ce qui, prétend-on, donne une lumière plus vive.

Lubrification automatique. . . . . . [Page 732.]

Cet acticle donne une courte description d'un système de lubrification automatique pour les stations de force motrice, les machines et les générateurs. Il est en usage à St. Louis. Depuis son installation on a économisé plus de $300 par mois sur le coût de l'huile et $150 par mois sur le coût de la main d'oeuvre. L'huile est amenée aux supports par une pompe à vapeur, ce qui fait considérer le système plus effectif que si l'on se servait de la gravité.

Un nouveau joint en cuivre. . . . . . [Page 733.]

C'est une pièce de cuivre rectangulaire d'environ 76 mm. de longueur, 3 mm. d'épaisseur et 38 mm. de hauteur. On la presse au moyen de ressorts d'acier contre les rails en dedans des plaques allongées. Les surfaces sont amalgamées.

Nouveau générateur pour tramways. . . . . [Page 733.]

Parmi les points spéciaux de ce générateur sont: une méthode d'opérer la pièce qui tient la brosse dans une direction parallèle à l'axe ce qui dispose de la tendance qu'ont les brosses à couper le commutateur; l'enlèvement des pièces polaires et des bobines sans déranger l'empiècement ou l'armature; une ventilation complète. La gravure montre une machine de 800 kw. pour Oakland, Californie.

Importantes usines électriques à Chicago. . . [Page 734.]

C'est la description des usines de la Siemens & Halske Co. d'Amérique. Cette compagnie n'a pas encore fait de moteurs de railways, mais elle construit des générateurs de toute espèce, parmi lesquels des générateurs de railways d'une capacity de 1500 kw., des moteurs pour automobiles, des lampes à arc électrique, des wattmètres, etc. Le modèle des générateurs pour railways a récemment été changé et est l'objet d'illustrations complètes. Le cadre de l'aimant est en acier fondu, et les pièces polaires sont d'un type spécial. L'armature a une grande surface et un fort diamètre tandis que sa profondeur est relativement petite. Ceci donne une bonne ventilation, avec une petite différence de potentiel entre les barres adjacentes du commutateur. Des conduits d'air rayonnent à fréquent intervalle à travers l'armature et les rais du cadre de l'armature sont arrangés de manière à lancer des bouffées d'air par ces passages. Le commutateur a un diamètre considérable, quoiqu'il ne soit pas placé en dehors des bobines et des conducteurs de l'armature, comme c'est le cas dans les premières machines de Siemens & Halske et les machines européennes. Les supports des brosses sont d'un type spécial destiné à assurer une pression constante des brosses contre le commutateur. La manufacture des moteurs d'automobiles est une spécialité de la compagnie et les usines peuvent manufacturer 125 moteurs de cette sorte par semaine. Ils ont une capacité de 2 kw. mais sont destinés à marcher continuellement à 4 chevaux avec une augmentation de température ne dépassant pas 40 degrés centigrades. La même compagnie construit aussi un grand nombre de convertisseurs rotatifs.

Tête de vapeur à épuisement. . . . . . [Page 737.]

Dans cette tête de vapeur à épuisement l'eau est séparée de la vapeur à l'aide de la force centrifuge.

Interrupteurs de circuit. . . . . . [Page 737.]

Cet interrupteur ne peut être fermé que si les conditions du circuit sont normales, de sorte qu'il n'y pas de danger d'âbimer les appareils de circuit ou d'opération. Le circuit est ouvert avec beaucoup de soin et la production d'arcs est réduite à un minimum.

Nouveau joint isolateur. . . . . . [Page 737.]

Ce joint sert à unir deux fils isolés. On commence par enlever la matière isolante de l'extrémité des deux fils puis on les glisse dans un manchon de cuivre. Deux vis qui traversent ce manchon tiennent les fils en position. Ce manchon a une enveloppe de caoutchouc durci et deux chapes de caoutchouc mou que l'on fait alors glisser par dessus le joint, isolant complètement toutes les parties métalliques. Les deux fils peuvent être séparés en retirant les chapes et desserrant les vis. Ce joint est spécialement adapté pour établir les communications entre les extrémités des fils projetant des enveloppes de moteurs sur les voitures.

Une jolie voiture pour Braintree, Massachusetts. . [Page 738.]

Cette illustration montre une voiture ouverte à 15 bancs qui a joui d'une grande popularité sur les railways électriques d'été qui ont un trafic considérable. Cette voiture a une longueur totale de 13,9 m. et une largeur de 2,2 m. La seconde gravure montre un nouveau truck construit par la même maison. La distance entre les essieux est exceptionnellement petite ce qui rend ce truck très pratique sur les lignes qui ont des courbes de petit rayon.

Compagnie importante de mica à Chicago. . . [Page 738.]

Cet article parle d'une compagnie qui prétend faire le commerce le plus étendu de mica en Amérique.

Savon pour nettoyer les voitures. . . . . . [Page 739.]

Cet article décrit un savon spécial pour nettoyer les voitures qui a été adopté par un grand nombre de compagnies de chemins de fer et de tramways en Amérique. Les expériences qu'ont faites ces compagnies leur ont demontré que de fréquents nettoyages conservent la peinture et le vernis des voitures, mais que l'eau avec du savon ordinaire n'est pas très désirable pour cet usage. Un certain nombre de compagnies nettoient leurs voitures avec ce savon deux fois par semaine, tandis que d'autres compagnies considèrent une par semaine tout à fait suffisant.

Le railway électrique Toledo, Fremont & Norwalk. [Page 740.]

Cette ligne a 100 km. de long et est actuellement en construction. La force motrice y est destribuée par le système trois-phasé à 15000 volts changées en courant direct pour service sur la ligne.

Machine pour arracher les vieux rails. . . . [Page 740.]

Cette machine peut arracher les rails d'environ 3,2 km. de voie par jour; elle brise les rails de la longueur que l'on vent, généralement entre 1,2 et 2,4 m. Le rail que montre la gravure a 150 mm. de hauteur, mais la machine peut briser des rails de 225 mm. de hauteur.

Une nouvelle entreprise en Allemagne. . . [Page 740.]

La maison dont il est question a pris l'agence d'un fabricant bien connu de caissons de voitures. Ces caissons sont expédiés en Allemagne où ils sont montés. Une commande pour voitures de cette sorte a été récemment reçue de Berlin. La même maison fournit aussi des trucks et des freins à air comprimé.

Double truck 14 B-3. . . . . . [Page 741.]

Ce truck a seulement 1,22 m. de distance entre les essieux et est destiné au service des lignes à fortes courbes. La voiture est bien suspendue. Les moteurs sont placés en dehors des essieux au lieu d'être entre eux; et c'est l'appareil des freins qui est entre les essieux.

Garde perche de trolley et dévidoir. . . . [Page 742.]

Cet instrument est destiné à empêcher la perche de trolley de bondir à une position verticale dans le cas où la roue quitte le fil de trolley.

Joint de rails Atlas. . . . . . [Page 742.]

Ce joint est devenu d'un usage très commun en Amérique. Nous donnons l'illustration de ses deux formes.

Soupape de sûreté automatique. . . . . [Page 742.]

Cette soupape de fermeture est distinée à être placée dans le tuyau principal entre les chaudières et les machines. Elle se ferme automatiquement quand il se produit dans le tuyau principal où à la machine une brisure suffisante pour réduire légèrement la pression de la vapeur. Sa construction est indiquée dans la coupe de cette invention qui figure parmi nos gravures.

Régulateur hydraulique de la clef de tirage. . . [Page 743.]

Cette invention ouvre ou ferme la clef de tirage suivant la pression dans les chaudières, de manière à tenir cette pression constante.

Supports à billes pour tramways. . . . . [Page 743.]

Les supports pour un essieu sont tous contenus dans une boîte renfermant les extremités de manière à pouvoir être enlevés et replacés à volonté. Les billes elles mêmes sont en acier durci et poli. La compagnie garantit une économie de force motrice variant entre 10 et 15 pour cent.

Filtre à huile. . . . . . [Page 743.]

Ce filtre renferme quelques nouveaux points et contient aussi un séparateur au moyen duquel l'huile de déchêt et l'eau provenant de la tige de piston et de la soupape de fuite sont séparées. L'huile est alors amenée à une chambre de rafinage où elle est chauffée et clarifiée. On la filtre ensuite à travers les déchêts de coton ce qui la débarasse des legères impuretés. Chaque filtre est pourvu d'un fort verre grossissant qui permet d'inspecter l'huile purifiée.

Appareil à transporter le charbon à Washington. . [Page 744.]

La gravure montre une vue de cet appareil prenant les cendres aux chaudières et les charriant à la fosse à cendres. Le tunnel a environ 61 m. de long. Le même sceau apporte le charbon aux chaudières.

Accouplement automatique pour wagons. . . [Page 744.]

Les gravures montrent deux types d'une marque d'accouplements de wagons dont on se sert, pour ainsi dire, sur tous les chemins de fer élevés en Amérique ainsi que sur un grand nombre de lignes à niveau. Plus de 50000 de ces accouplements sont maintenant en usage. On s'en sert aussi dans beaucoup de villes d'Europe.

Grande production de fils métalliques. . . . [Page 747.]

La compagnie mentionnée prétent posséder l'usine la plus importante qui existe pour la production de conducteurs électriques et de fil de fer. Toute espèce de fils métalliques y sont manufacturés.

Nouvelle usine à freins. . . . . . [Page 747.]

Cette article décrit la nouvelle usine d'une compagnie qui manufacture énormément de freins à air comprimé pour tramways. Toute la force motrice est distribuée à travers l'usine par l'électricité ou l'air comprimé.

Une importante maison de commere anglaise. . [Page 748.]

La maison a été établie en 1800 et vend toute espèce d'instruments de mesure, faisant une spécialité des instruments d'enrégistrement requis en Angleterre par le Board of Trade.

Air emmagasiné pour les freins de voitures. . [Page 748.]

Par ce système l'air est comprimé dans la station de force motrice à environ 15 atmosphères et est alors emmagasiné dans les réservoirs des voitures. Avant d'être appliqué aux freins cet air passe à travers une soupape de réduction qui réduit la pression à environ trois atmosphères. Les voitures ne sont pourvues d'aucune machine à comprimer. La compagnie qui s'est formée il y a un an environ, a déjà équipé 43 voitures par ce système qui a donné des résultats satisfaisants et qui, prétend-elle, a de nombreux avantages.

Quelques récents travaux électriques en Angleterre. [Page 749.]

C'est la description des ouvrages d'un fabricant bien connu d'appareils pour railways électriques.

Resúmen de los Artículos—Octubre, 1899.

Práctica ferro-carrilera eléctrica en América como se ejemplifica en Chicago. . . . . . [Pág. 613.]

Los sistemas de la superficie ferro-carrilera de Chicago son operados por diez compañias independientes y el sistema del ferro-carril elevado por cinco. Algunas de las principales líneas corren aun por el sistema de cable, pero, la mayor parte del derecho de peage por milla, es actualmente eléctrico y se intenta, tan pronto como sea posible, cambiar las líneas de cable por las eléctricas. Los ferro-carriles caballares han casi desaparecido de Chicago, habiendo solo unas pocas líneas alimentadoras para las de cable. Las elevadas son todas operadas por electricidad, formando, de mucho, los mayores sistemas eléctricos elevados en el mundo. Hay naturalmente un gran número de estaciones de fuerza motríz en Chicago que corren estas propiedades independientes y se dan ilustraciones de la mayor parte de ellas demostrando el arreglo de la maquinária etc. asícomo en diágramas escalonando de tal modo los tamaños relativos de las estaciones cuyas pueden prontamente verse. Casi todas las mayores estaciones de fuerza motríz son corridas sin condensantes y hay solo en la ciudad tres ó cuatro de ellas. La incapacidad de tener suficiente abastecimiento de agua á una tasa razonable, ha inducido al uso de remendar torreones y bancos por los cuales el agua para la condensación es usada varias veces. La superconstrucción de Chicago, si bien nada tiene que admirarse en ella particularmente, es, sin embargo, digna de atención y especialmente con respecto á los enganches soldados cuyos se han llevado aquí á un alto grado de perfección. La construcción aérea ó superior es muy buena aunque sencilla habiéndose dado ó hecho poca atención al ornato y sí mas bien á los estorbos ú obstrucciones que pudiera ocasionar á las calles. Cierra este artículo con una descripción de los métodos de construcción de la nueva Northwestern Elevated con ilustraciones.

Práctica ferro-carrilera eléctrica en Alemánia. Por Louis J. Magee. [Pág. 647.]

Este artículo contiene una de las mas valiosas descripciones de la práctica alemana por el director gerente de la Union Elektricitäts Gesellschaft, una de las mayores compañias manufactureras de Alemánia. La propiedad de los tramvías alemanes es discutida largamente indicándose tambien las relaciones de los mayores sindicatos financieros ó grupos de la indústria de tramvías asícomo la influencia que dichos grupos han tenido sobre el rápido desarrollo en Alemánia y que dificilmente puede calcularse. La peculiaridad primordial de la práctica alemana, segun se distingue de la americana, es en el uso del sistema mixto de tracción eléctrica por la que, los carros son impelidos, en el centro de las cindades, por baterías de depósito y en las afueras, por el sistema aéreo de alambre. Otra de las cosas que Alemánia hace, que en nada se parezca, dada la misma extensión que la de América ó de cualesquiera otra parte del mundo, es en la construcción de los polos ornamentados, combinación de trolley y postes para el alumbrado, etc., todo esto, de una manera interesante y es evidente que Alemánia ha llevado la ciencia de la ingeniería eléctrica de tramvías á un alto estado de desarrollo.

Práctica ferro-carrilera eléctrica en la Gran Bretaña. Por Sidney H. Short. . . . . [Pág. 663.]

El profesor Short ha llevado junto con este artículo várias de las principales peculiaridades de la práctica inglesa y define las dificultades que han inducido al desarrollo de la indústria en aquel pais hasta la época presente debidas á las restricciones impuestas por la acción parlamentária y por el crecido deseo de la propiedad municipal como contraria á la empresa particular. Los detalles técnicos de la superconstrucción, construcción aérea ó superior, existencia de material etc. se ilustran y describen cuidadosamente.

Característicos financieros de los sistemas ferro-carrileros de las mayores ciudades del mundo. Por Edward E. Higgins. [Pág. 680.]

Una compilación de las estadísticas del derecho de peage por milla, inversión, recetas y gastos de los ferro-carriles en ciudades de más de 500000 habitantes en todo el mundo, arreglado de tal manera que demuestra los beneficios comparativos y las oportunidades para la inversión.

Práctica ferro-carrilera eléctrica en Austro-Hungría. Por E. A. Ziffer. . . . . [Pág. 685]

El primer ferro-carril eléctrico en Austria para el servicio de pasajeros fué abierto en 1883 y era de 4 km de extensión; el de Hungría en 1889. Esta última línea fué construida con el sistema de conducto subterráneo. Este conducto se demuestra en la pág. 687. Se usa extensamente en Budapest y está instalándose en Viena. El sistema del trolley, sin embargo, es el que generalmente se usa. Dánse aberturas por el gobierno general á compañias particulares, pero, su duración es limitada á sesenta años. Las municipalidades tienen tambien el derecho de construir y operar ferro-carriles urbanos. Todos los caminos ferro-carrileros de segunda importancia se hallan tambien libres de impuestos del estado por un período de 20 años y en algunos casos exentos de los de la municipalidad. El que escribe dá luego una lista de los ferro-carriles eléctricos, con un promedio de extensión, entrevía, la conducción de pasajeros y las recetas. Los rieles, en las ciudades, son trazados yá en concreto ó piedra picada á una profundidad de 30 cm y pesan desde 34 á 43 kg por m. En los afueras de los límites de la ciudad, úsanse los rieles Vignole, desde 21 á 23 kg por m sobre travesaños de madera ó de metal. Sigue describiendo, el que escribe, la práctica en las uniones de rieles, alimentadores y polos. El alambre del trolley es usualmente de cobre duro derretido, desde 7 á 8,25 mm de diámetro. La Baden-Böslau usa alambre silíceo bronceado, de 7 mm de diámetro. En algunos casos el tope ó parte superior alambre del trolley está cubierto por un protector de madera sujeto á su puesto por pinzas de metal, afin de prevenir la caida de alambres telefónicos ó de telégrafo y evitar así todo contacto. El carro mas popular es el llamado tipo Hamburg con una plataforma larga á cada extremo y una capacidad de asientos para 20 pasajeros. El largo, sobre todo, es de 3,4 m. En las ciudades pequeñas los carros varían desde 5,8 á 7 m de extensión sobre todo. El que escribe, describe luego los tipos de corriente, colectores ó trolleys. La velocidad en todos casos está prescrita por las autoridades y es usualmente de 15 km por hora. Esta puede ser aumentada á 18 km en las calles de poco tráfico, pero, debe reducirse á 10 km en las calles que son estrechas y adonde haya tráfico considerable. En los suburbios se permite una velocidad desde 25 á 30 km por hora. La mayor parte de las grandes estaciones de fuerza motríz operan condensantes y usan unidades directas conexionadas. Las páilas son del tipo de tubería de agua y el consumo de carbón por kw hora varía desde 8 á 8,5 kg. Usanse, algunas veces, economizadores y siempre los calentadores alimentadores de agua. Sigue, el que escribe, describiendo brevemente los caminos ¡ndustriales y mineros.

Práctica ferro-carrilera eléctrica en la Argentina. Por E. Manville. . . . . [Pág. 693.]

El Señor Manville, quien es miembro de la muy conocida firma de ingeniería de Kincaid, Waller & Manville, de Lóndres, quienes asímismo se han ocupado, como ingenieros, de la construcción de ciertos tramvías en Buenos Aires, describe condiciones bajo las cuales se obtienen las concesiones de tramvías en la Argentina, lo propio los problemas físicos y otros que puedan sobrevenir. Hay considerable repugnancia en conceder largo tiempo para franquícias

en la Argentina y las compañias se hallan decididamente bajo el mando de la municipalidad cuya impone un impuesto de seis por ciento sobre los productos brutos para la conservación del adoquinado ó pavimento de los caminos en los que se hallan situados los tramvías y coloca otros cargos sobre las compañias de los mismos cuyos son fuertes si bien nó prohibitivos. Usanse tres clases de superconstrucciones en Buenos Aires, segun sea el tráfico. En una, los rieles están sostenidos sobre una base de concreto completo; otra, sobre largueros de concreto longitudinales, y en el tercero sobre travesaños transversales sencillos sin concreto. En el sistema de distribución, la forma potencial máxima permitida es muy pequeña, siendo llevado á cabo este resultado por el uso de los dinamos auxiliares (boosters) negativos, mientras que alimentadores positivos, cargando á los puntos extremos del sistema, tienen dinamos auxiliares positivos. La construcción aérea ó superior y el sistema de alimentador subterráneo, en la Argentina, es escelente y la existencia de material es tambien buena. La fuerza motríz se obtiene principalmente de las estaciones locales cuyas son varias trabajando en grande escala.

Funcionamiento de los motores ferro-carrileros. Por W. B. Potter. . . . . [Pág. 701.]

El que escribe es ingeniero gefe del departamento ferro-carrilero de la General Electric Company. Manifiesta que la fuerza motríz caballar de los motores construidos por su compañia, son avalorados segun un modelo arbitrario, basado en una subida temporal de la temperatura del motor á 75 grados centígrado en una hora bajo una carga llena y aquella presumiendo ser, por el aire que la rodea, de 25 grados centígrado. El motor no puede ser operado á dicho avalúo de producto contínuo, pero, puede trabajarse arriba del citado avalúo, á cortos intérvalos de tiempo sin perjuicio. El promedio de la fuerza motríz caballar, conducido por un motor durante el dia, no debiera ser mayor de 30 por ciento del avalúo antes mencionado. Cuando se usan retrancas eléctricas, el motor debiera ser de 20 á 25 por ciento, mayor de capacidad, que cuando no se usan. Bajo las condiciones ordinarias de la ciudad, la fuerza motríz caballar, requerida para los motores, debiera ser en su peso total de toneladas multiplicadas por la velocidad máxima de millas por hora á nivel y divididas por 5. Si la velocidad maxíma es desconocida, puede tomarse como la doble de la cédula de dicha velocidad. Esta regla debiera, sin embargo, ser aplicada con cautela y solo indica la capacidad mínima bajo condiciones ordinarias. En el servicio ordinario de calle, el esfuerzo tractivo, durante la aceleración, es entre 10 y 15 por ciento de la carga que conduce. En el servicio elevado ó suburbiano es generalmente desde 5 á 7½ por ciento, mientras que, en trabajo de flete, adonde se usan velocidades despaciadas, puede que no exceda de 1½ ó 2 por ciento. En el servicio ordinario, el peso de las ruedas viajando, debiera ser, á lo menos, seis veces mayor del esfuerzo tractivo que se requiera. La capacidad aproximada de una fuerza motríz, de la estación, para cualquier servicio, es de cerca 100 horas watt por tonelada y milla á velocidades ordinarias.

Sistema electro-neumático para refrenar ferro-carriles y otros motores. . . . . . [Pág. 703.]

Este sistema está en uso en Pittsburgh y Wilmerding, adonde dos ó mas carros motores se ponen ó arreglan dentro de un tren y cada carro tiene su propio registrador, haciéndose necesario, para dichos registradores, ser movidos en sincronismo igual ó exacto, de manera que, todos los motores corran á una misma velocidad. La operación de todos los registradores, es dirijida desde la plataforma del frente del primer carro y se ejecuta por fuerza motríz de aire. En el tope ó parte superior de cada registrador, hay dos cilindros de aire, uno de los cuales conduce un linguete ó retén que se engrana con una rueda de trinquete en la parte superior del registrador. Los cilindros de aire son operados en armonía por una batería eléctrica pequeña y por un conmutador eléctrico, pequeño tambien, al frente de la casilla del maquinista. El segundo cilindro de aire, es para retornar el registrador á una posición O, y es operado tambien por el hombre encargado del motor en la plataforma del frente. El circuito del rompedor ó partidor, está de tal modo arreglado, que impulsará los registradores á una posición opuesta ó hácia afuera, en el caso de que se abrieran. Si se aplican las retrancas de aire, todos los registradores retornan automáticamente á la posición opuesta ó hácia afuera antes mencionada. El comprimidor de aire que se ilustra es tambien de nuevo tipo y consiste de una bomba de dos cilindros rotativa directamente impulsada por un motor pequeño. En las carretillas de carro que se usan, el muelle de apoyo para los motores, se guarda de una manera enteramente distinta que la del muelle de apoyo de los carros.

Un gran fabricante de efectos eléctricos. . . . [Pág. 708.]

Hace una especialidad de alambre y uniones de rieles.

Aparato de fuerza motríz de transmisión en Nueva York. [Pág. 709.]

Esta es una descripción de los generadores de corriente alternante, convertidores rotativos y transformadores para ser usados por la Metropolitan Street Railway, de Nueva York. Los generadores son del tipo giratorio de influencia magnética, con armaduras externas estacionárias. Cada máquina tiene una capacidad de 2500 kw, generará una corriente de tres fases de 6600 volts á una frecuencia de 25 ciclos por segundo y correrá á 75 revoluciones por minuto. La influencia magnética giratoria tiene 40 polos y está montada directamente con el eje de la máquina. Está muy bien ventilada. Cada carrete-boblar es probado con una corriente alternante de 25000 volts. La armadura es de hierro fundido y arreglada con una base de planchas corredizas de manera que pueda removerse á un lado hasta verse límpia ó libre de la influencia magnética, lo que permite ó dá acceso á una inspección y reparaciones, á ambos, esto es, á la armadura y la influencia magnética. La influencia magnética giratoria está compuesta de un anillo de acero, cuyo está firmemente empernado á un bastimento de hierro fundido á rayo con el eje de la máquina. Los transformadores en su parte inferior al convertidor rotativo de las estaciones, son de 250 kw cada uno y tres son los requeridos para operar cada convertidor rotativo. La primera enrolladura del transformador está designada para 6000 volts y la segunda para 350 volts. Los transformadores se enfrian por aire cuyo se sopla dentro de ellos teniendo una eficiencia, á una carga llena, de 98,22 por ciento. Los transformadores rotativos son de 990 kw cada uno y operan á 214 revoluciones por minuto. La influencia magnética tiene diez y ocho polos hechos de hierro fundido. La enrolladura de la armadura es hecha de barras de cobre. Las escobillas, al extremo alternante del convertidor rotativo, son de cobre, y el mismo opera como una máquina de seis fases. Dáse salida á los convertidores rotativos de la corriente directa por medio de otra abastecida por baterías de depósito.

Nuevo tipo de máquinas de dos cilindros. . . [Pág. 711.]

La novedad principal de esta máquina consiste en el método de operar las válvulas de admisión en los cilindros de baja presión. Estas válvulas son operadas, en parte, de un excéntrico fijo en el eje de la máquina y de otra, por el del mismo excéntrico cuyo opera las válvulas en la alta presión del cilindro. Las últimas son, por supuesto, refrenadas por el moderador de excéntrica. Se pretende que por este método de operar la baja presión de las válvulas, se evitan las desventajas ocasionadas por operarlas enteramente de un excéntrico fijo en el eje de la máquina, ó, exactamente de acuerdo ó en armonía con las válvulas de alta presión.

Acumuladores para tracción. . . . . . [Pág. 712.]

Este describe un acumulador inglés bien conocido. Las planchas son formadas por el procedimiento de Planté, con ácido sulfúrico solamente y toma cerca de seis semanas. Las planchas están todas conexionadas á una barra larga sin tornillos. No se usan ningunos materiales mas que vídrio y plomo al lado de las celdas y las baterías son mantenidas bajo una garantía de un precio variando desde 3 á 6 por ciento de su costo. Hánse usado extensamente en la Gran Bretaña y en otras partes como reguladores de fuerza motríz en las estaciones.

Nuevo tipo de motores de ferro-carriles urbanos. . [Pág. 713.]

Este describe cinco tipos de motores recientemente puestos en el mercado por la misma compañia y varian en tamaño desde 30 á 150 caballos de fuerza. Los dos primeramente descritos (Nos. 68 y 69) están de tal modo arreglados que con remover cuatro pernos y desuniendo los muelles que lo suspenden, el motor entero puede removerse de debajo del carro por un gato ó cric corriendo en una excavación ó depósito. Un carro equipado con estos motores cambia comunmente de motores un dia por otro lo que permite una inspección cuidadosa. Están adaptados ya sea para grasa ó aceite lubricado y el aceite es alimentado entre los engranes adonde la presión es menor. El tercer motor (No. 56) está designado para ser inspeccionado mientras se halla en el carro sin desmontarlo con frecuencia. Está compuesto de dos partes engoznados en el centro y con destornillar un perno, la mitad de la parte inferior puede balancearse abajo dentro de una excavación ó depósito y la armadura puede retenerse ya sea en la mitad de la parte superior ó de la inferior si asi se desea. El cuarto motor (No. 70) y el quinto motor (No. 50 C) están designados para trabajo duro y son de 110 á 150 caballos de fuerza de capacidad cada uno. Están asimismo designados para ser montados en carretillas de carro cuyas pueden ser corridas debajo del carro y la mitad de la parte superior del motor puede luego removerse. Todos los motores son á prueba de polvo y á cubierto de agua, provistos ademas con piezas de polo laminadas, cuyas están empernadas á los enganches ó yugos, en lugar de ser fundidas dentro de estos.

Uniones de rieles. Por W. F. Ellis, C. E. . . [Pág. 715.]

La última forma de la conexión de la mordaza en la unión se demuestra en las Figs. 2 y 3. Esta se ha mejorado en la construcción del trayecto ordinario por la forma demostrada en las Fig. 1 y 4. Estas no son consideradas de desear por el que escribe, entre otras razones siendo la de que el riel se rompería ó cortaría dentro del travesaño, segun se demuestra en la Fig. 4, lo que causa que la mordaza forzaría los pernos. Las Figs. 5 y 6 demuestran dificultades con la mordaza ordinaria, producidas aquellas si los agujeros no son taladrados con propiedad. Como un remedio, el que escribe, recomienda la unión demostrada en las Figs. 7 y 8 aplicadas á los rieles Vignole. La Fig. 9 demuestra la unión ordinaria aplicada á los rieles americanos modelo y la Fig. 10 la unión mejorada.

Nueva fábrica de carbono. . . . . . [Pág. 716.]

Estos describen una nueva fábrica cuya se ocupará de la fabricación de las escobillas de carbono. Esta situada en las regiones carboníferas y de hulla carbonizada de Pennsylvania; se empleará asimismo, en gran escala, el gas natural en sus trabajos para hornear y otros propósitos.

Estribos ó marchas de carro que no resbalan. . . [Pág. 716.]

Estos estribos ó marchas son hechas de rebordes de acero con plomo vaciado dentro de las ranuras abiertas. Usanse muchísimo para estribos de carros y marchas para las estaciones de los ferro-carriles elevados.

Manufacturero inglés de ruedas de fundición maleable. [Pág. 716.]

La firma mencionada pretende ser la exploradora de la manufactura de ruedas de fundición maleable en la Gran Bretaña.

Máquinas movidas por el gas para el servicio ferro-carrilero eléctrico. . . . . . Pág. 717.]

Estas describen un nuevo tipo de máquinas movidas por gas para operar generadores eléctricos, construidos desde 10 á 650 caballos de fuerza, con dos ó tres cilindros, dependiendo del tamaño. La sección de la máquina presentada es por medio de un cilindro de una máquina de tres cilindros, estos tres siendo exactamente iguales. La máquina es de simple acción y cada émbolo recibe un impulso á cada golpe por segundo. El gas está mezclado con aire antes de ser admitido al cilindro por medio de la abertura M y de la válvula J. El gas es encendido por una chispa eléctrica en F y despues expelida por medio de la válvula expulsora E y la de la descarga O. El método de gobernar la velocidad es radicalmente diferente de la mayor parte de las máquinas movidas por gas hechas, en las que, el número de explosiones son variadas segun los requerimientos de fuerza motríz. En la máquina ilustrada ocurre una explosión en cada cilindro á cada golpe de segundo, pero, el montante de gas admitido es variado segun los requerimientos de la carga. Se ilustra el moderador de excéntrica para hacer esto. Estas máquinas han estado en uso en una línea de 5 km en Huntington, New York, operando dos generadores de 37 kw.

La historia de una gran compañia manufacturera alemana. [Pág. 719.]

Esta describe el progreso de la Allegemeine Elektricitäts Gesellschaft, cuya principió en 1882 y ahora tiene un capital de 47000000 de marcos ($12000000) y un excedente de 18000000 de marcos ($4500000) dando empleo á 12000 hombres. Todos los utensilios en los talleres de Berlin son operados directamente por motores eléctricos. La corriente se toma de un edificio ó planta de fuerza motríz. La compañia tiene tantas órdenes que los trabajos andan de dia y de noche. Se hace referencia especial á la maquinária de tres fases de la compañia y este sistema es usado para distribuir la fuerza motríz en los talleres. La compañia ha hecho una especialidad de esta clase de aparatos.

Perfeccionamiento en las retrancas eléctricas. . . [Pág. 721.]

La retranca descrita es una que consiste de un disco de hierro fundido á rayo con el pivote del carro y un zapato de freno circular electro-magnético cuyo está sostenido de tal modo que no puede girar, hallándose apretado contra el disco por la corriente de los motores que actúan como generadores. Dáse un diágrama enseñando la conexión eléctrica del registrador que se usa.

Nuevo tipo de conducto y sistema de contacto en la superficie. [Pág. 721.]

El grabado demuestra una sección de una caja para conservar muerto el contacto de los rieles escepto cuando pasa el carro. La barra 4 se vuelve atrás por un ingenio de contacto en el carro haciendo revolver la barra 3. Esto ocasiona que el disco 9 se revuelva y hace que los contactos sean apropiados. La corriente puede luego ser tomada de la superficie de la calle ó del conducto regular. Los muelles llevan las partes de vuelta á sus posiciones originales.

Una compañia importante de ingeniería y contratista en Chicago. [Pág. 722.]

Retrancas de aire. . . . . . [Pág. 723.]

Este artículo dá algunos particulares de dos tipos de retrancas de aire hechas por una compañia bien conocida. En cada una de ellas el freno con tornillo de presión es impelido del pivote por medio de engranes. Dicho freno, con tornillo de presión, está de tal modo arreglado que solo opera cuando la presión en el depósito cae bajo de un cierto límite. La compañia construye tambien una retranca de aire para usarla con un motor de tornillo de presión, descrito en nuestro número de Abril. Dánse las vistas del primer freno citado, lo propio que de la válvula operadora en la plataforma. La válvula conduce una vara ó probeta de presión.

Instrumento medidor eléctrico. . . . . . [Pág. 724.]

Los grabados demuestran un amperómetro y voltímetro hechos por un fabricante importante de Inglaterra bajo privilegios concedidos á Lord Kelvin. El mismo fabricante hace toda clase de instrumentos medidores para corrientes directas y alternantes.

Nuevo tipo de calentador para carro. . . . [Pág. 724.]

La Fig. 1 demuestra un calentador eléctrico para carros teniendo asientos longitudinales. El calentador está hecho de dos carretes-boblares de alambre incorrosivo suspendido de una cuerda sólida de amianto (B), unida á los extremos de unos aisladores de porcelana redondos acanalados (D). La cuerda conserva los carretes-boblares á puesto sin usar ninguna tensión en el alambre.

Purificadores de alimentadores de agua y calentadores. [Pág. 725.]

Estos se hallan en uso en las localidades adonde la cal ú otros sólidos están contenidos en el alimentador y son intencionados para extraer este material antes que el agua sea introducida dentro de las páilas, El que se describe es un alimentador-calentador abierto, esto es, los ingredientes se remueven del agua directamente por la acción del vapor. La construcción del calentador se demuestra en la Fig. 1. Consiste de una série de quícios encorvados hechos de plancha de acero. El agua es admitida al tope del quício y fluye sobre los bordes en una película delgada y se adhiere al lado de debajo hasta que llega á su ínfimo punto, goteando enseguida dentro del quício que le sigue y de este modo al fondo del juego de quícios. El receptáculo en el cual están contenidos dichos quícios se llena de vapor y las impurezas presas ó asidas en la solución, son depositadas en el lado de debajo de los quícios. Estos están hechos en longitudes de cerca 1,8 m y pueden prontamente removerse para limpiarlos. La Fig. 2 ilustra un instrumento para taladrar los cilindros y sostener los quícios.

Un mango de retranca dentado. . . . . [Pág. 725.]

Este está compuesto solo de cuatro piezas segun se demuestra en los grabados.

Instalación de una gran batería de pósito en Plymouth. [Pág. 726.]

Esta consiste de 260 celdas, teniendo un producto de 120 amperes á 480 volts para cinco horas.

Nuevas locomotoras de gran velocidad. . . . [Pág. 726.]

Esta es una locomotora inglesa de acción sencilla y del tipo de empuje constante, estando arreglada con dos manúbrios cilíndricos de 180 grados aparte, ó de tres cilindros con manúbrios colocados 120 grados aparte. La ilustración enseña una locomotora de 250 caballos de fuerza, acoplada directamente á un generador de corriente alternante.

Válvulas sopladoras. . . . . . [Pág. 726.]

Este artículo contiene una vista general y seccional de una válvula sopladora para páilas y tuberías de vapor, cuyas han obtenido y ganado una prominencia considerable. Las novedades principales se demuestran en la ilustración seccional y consisten de un arreglo por el cual la recaudación del empósito y sedimento en el tope del disco de la válvula se previene. El disco puede tambien revertirse facilmente y el asiento de la válvula puede removerse cuando se desgasta.

Gran carro de arrastre. . . . . . [Pág. 727.]

Este carro mide 11,9 m sobre todo. Contiene diez asientos reversibles y cuatro estacionarios con una capacidad de asientos para setenta pasajeros. El carro pesa 8300 kg y está montado sobre dobles carretillas de carro cuyas pesan menos de 1810 kg cada una.

Bombas alimentadoras. . . . . . [Pág. 727.]

Estas describen una páila con bomba alimentadora hecha en Glasgow, cuya está en uso en varios de los mayores vapores oceánicos y en varias estaciones de fuerza motríz tambiem, La bomba es impulsada directamente desde la varilla del émbolo y no hay ninguna punta muerta.

Fuerza motríz económica de generación. . . [Pág. 728.]

El horno construido para quemar la basura de la calle como combustible y descrito en nuestros números de Mayo y Julio de 1898, ha sido, desde entonces adoptado en una extensión considerable. Los fabricantes de esto hacen tambien un foguero mecánico cuyo dá escelentes resultados segun se demuestra por el texto publicado. Asímismo hacen una máquina para determinar el montante de ácido carbónico de los gases que pasan desde un horno, determinando tambien de este modo si el propio montante de aire ha sido admitido en el hogar. Una pérdida de economia resultará si se usa demasiado aire ó poco en la combustión. La ilustración enseña este ingenio.

Talleres de construcción de carros en Preston, Inglaterra. [Pág. 729.]

Estos dan las vistas y descripción de un extenso edificio recientemente concluido para la construcción de tramvías y carros ferro-carrileros lijeros en Inglaterra. Los talleres tienen una capacidad para la manufactura de 800 carretillas dobles de carro, de tamaño ordinario, por año. Toda la maquinaria es operada por motores eléctricos, de los cuales hay 25 en los talleres. La fuerza motríz es generada desde una estación central centeniendo una máquina y generador de 325 caballos de fuerza. La compañia manufactura tambien carretillas de carro y asímismo está preparada para abastecer carros equipados con cualesquiera de las carretillas de carro modelo que se construyan. Dánse vistas de algunos de los principales edificios y carros recientemente construidos.

Linternas de locomotora para carros eléctricos. . [Pág. 732.]

Los reflectores de estas linternas de locomotoras son corrugados produciendo, segun se pretende, una luz mas intensa.

Engrasación automática. . . . . . [Pág. 732.]

Esta es una corta descripción de un sistema de engrasación automática para las estaciones de fuerza motríz, máquinas y generadores en uso en St. Louis. Desde la instalación ha habido una economia de mas de $300 por més en el costo del aceite, y de $150 por més en el costo de labor. El aceite se bombea á los cojinetes por bombas de vapor y de ahí que el sistema se considere mas efectivo que si se usára la gravedad.

Aislador para el tercer riel. . . . . . [Pág. 732.]

Este consiste de un hierro maleable modelo intencionado para conducir un aislador, sobre el cual está montado un gárfio de hierro, maleable tambien, que sostiene el tercer riel. El gárfio sujeta el riel en alineación horizontal, pero, permite un juego ó movimiento vertical ligero. Fué intencionado para obviar la dificultad proviniente de la rotura de los aisladores que ocurrieron en el pasado á causa de que el riel estaba sujeto demasiado ríjido por los aisladores.

Nuevo generador para ferro-carril urbano. . . [Pág. 733]

Entre las novedades especiales de este generador hay un método para operar los mangos de las escobillas en una direccion paralela con el eje removiendo toda tendencia de las mismas en recortar ó tallar el conmutador, de la de remover las piezas del polo y carretes-boblares sin perturbar el yugo ó armadura asícomo tampoco la entera ventilación. El grabado enseña una máquina de 800 kw para Oakland, California.

Una unión nueva de bronce. . . . . . [Pág. 733.]

Esta es una pieza rectangular de bronce de cerca 76 mm de largo, 3 mm de espesor y 38 mm de alto, apretada contra los rieles dentro de las mordazas por medio de unos muelles de acero. Las superficies son amalgamadas.

Extensos trabajos eléctricos en Chicago. . . . [Pág. 734.]

Este describe los trabajos de la Siemens & Halske Company de América. La compañia no hace aun los motores ferro-carrileros, pero, fabrica toda clase de generadores, incluyendo generadores ferro-carrileros tan grandes como de 1500 kw, motores para automobiles, lámparas eléctricas de arco, metros watt, etc. El modelo de los generadores ferro-carrileros ha sido recientemente cambiado y se ilustra por completo. El bastimento del imán es de acero fundido, y las piezas del polo son de un tipo especial. La armudura tiene una gran superficie y diámetro, de una profundidad comparativamente pequeña. Esto dá una buena ventilación con pequeña diferencia potencial entre las barras adjuntas del conmutador. Conductos ó canales de aire radían frecuentemente por medio de la armadura. Los rayos del bastimento de la armadura están arreglados para echar soplos de aire por medio de dichos conductos. El conmutador es de gran diámetro si bien no está colocado afuera de los carretes-boblares é influencias magnéticas de la armadura, segun se acostumbra con las máquinas originales de Siemens & Halske y de las fabricadas en Europa. Los mangos de las escobillas son de un tipo especial y designados para asegurar una constante presión de las escobillas con el conmutador. La manufactura de motores para los automobiles es una especialidad y los talleres tienen una capacidad para manufacturar 125 motores de esta clase en una semana. Son de una capacidad de 2 kw, pero, están designados para marchar contínuamente á 4 caballos de fuerza con un aumento nó mas allá de 40 grados centígrado. La compañia fabrica tambien muchos convertidores rotativos.

Avance de vapor agotado. . . . . . [Pág. 737.]

En este avance de vapor agotado el agua es separada del vapor por fuerza centrífuga.

Rompedores de circuito. . . . . . [Pág. 737.]

Este rompedor no puede cerrarse á menos que la condición del circuito sea normal, de modo que no hay peligro que dañe el aparato en el circuito ó en operar. El mismo se abre muy cuidadosamente y el arqueo es reducido á su mínimo.

Nuevo conector aislador. . . . . . [Pág. 737.]

Este es para uso adonde dos alambres aislados tienen que conexionarse. Los extremos de los alambres están primeramente á descubierto de aislamiento con un dedal de bronce deslizado encima de ellos. Los dos tornillos, que pasan por medio del dedal, mantienen los alambres fuertes. Dicho dedal tiene una cubierta ó chaqueta de goma tiesa y dos casquillos de goma suave, cuyos se deslizan luego encima, aislando completamente todas las partes de metal. Los alambres pueden desunirse con deslizar afuera los casquillos de goma suave y luego aflojando los tornillos. Es especialmente adaptado para hacer las conexiones entre los extremos de los alambres proyectándose afuera de la envoltura del motor y de la de los carros.

Gran compañia de mica en Chicago. . . . [Pág. 738.]

Esta es una referencia de una compañia que pretende ser la mayor expendedora de mica en América.

Hermoso carro para Braintree, Massachusetts. . [Pág. 638.]

Este enseña un carro abierto de 15 bancos, cuyo ha obtenido mucha popularidad en los ferro-carriles eléctricos durante el verano teniendo un tráfico muy grande. Mide 13,9 m sobre todo y tiene un ancho de 2,2 m. El segundo grabado demuestra una nueva carretilla de carro construida por los mismos fabricantes. Tiene una base de rueda escepcionalmente pequeña y es intencionada para ser usada en los caminos con curvas de corto rádio.

Jabón para limpieza de carros. . . . . [Pág. 739.]

Este describe un jabón especial para la limpieza de carros cuyo ha sido adoptado por un gran número de ferro-carriles de vapor y compañias urbanas en América. La experiencia de estas compañias ha sido de que la frecuente limpieza preserva tanto la pintura como el barníz de los carros, no siendo de desear el agua con el jabón ordinario. Un número de compañias límpian los carros con este material dos veces á la semana, pero, en otros caminos una sola vez á la semana es considerada suficiente.

El ferro-carril eléctrico de Toledo, Fremont y Norwalk. [Pág. 740.]

Este camino es de 100 km de extensión y en la actualidad se está construyendo. La fuerza motríz es distribuida por el sistema de tres fases á 15000 volts cambiada á una corriente directa para uso de la línea.

Máquina para arrancar los rieles viejos. . . . [Pág. 740.]

Esta máquina puede arrancar cerca de 3,2 km de trayecto por dia, asícomo los rieles de cualquier longitud, usualmente desde 1,2 á 2,4 m. El riel que se demuestra en el grabado es de 150 mm de alto, pero, la máquina es capaz de arrancar los rieles de 225 mm de alto

Una nueva empresa en Alemánia. . . . . . [Pág. 740.]

La firma referida ha tomado la agencia de un fabricante bien conocido de cuerpos de carro. Estos son embarcados á Alemánia y puestos juntos en ese pais. Hánse recibido órdenes recientes para carros de esta clase para Berlin. La misma firma abasteció carretillas de carro y retrancas de aire.

La carretilla doble de carro No. 14 B-3. . . [Pág. 741.]

Esta carretilla de carro tiene una base de rueda de 1,22 m y es intensionada para el uso de caminos de curvas agudas. El carro tiene una solera con resorte de pasador. Los motores se conducen afuera de los pivotes en lugar de estar entre ellos y el aparejo de la retranca está entre los pivotes.

Enganche del riel Atlas. . . . . . [Pág. 742.]

Este enganche de riel ha sido adoptado extensamente en Amé rica é ilústranse dos formas.

Agarrador de polo de trolley y carretel. . . . [Pág. 742.]

Este es intencionado para prevenir que el polo del trolley brinque en una posición vertical en caso de que la rueda saltára del alambre del trolley.

Válvula de cierre automática de seguridad. . . [Pág. 742.]

Esta está designada para ponerse en la tubería principal de vapor, entre las páilas y las máquinas, y se cierra automáticamente cuando hay una rotura en la tubería principal ó en la máquina, lo suficiente para reducir levemente la presión del vapor. La construcción del ingenio se demuestra por el grabado seccional.

Regulador de tiro hidráulico. . . . . . [Pág. 743.]

Este ingenio abre y cierra el regulador de tiro segun sea la presión en las páilas, sosteniéndola constantemente en ellas.

Cojinetes de rodillo para los carros urbanos. . . [Pág. 743.]

Los cojinetes para un pivote están todos contenidos en una caja conexionando los extremos, de modo que puedan levantarse afuera y volverlos á colocar en cualquier tiempo que se desée. Los rodillos en sí son de superficie de acero duro y aguzados. La compañia garantiza una economia desde 10 á 15 por ciento de la fuerza motríz usada.

Filtradores de aceite. . . . . . [Pág. 743.]

Estos abrazan algunas nuevas formas y tambien contienen un separador por el cual el desperdicio del aceite y del agua de los derrames desde la varilla del émbolo, son separados. El aceite es luego puesto en un cuarto de refinar adonde se calienta y se clarifica. Mas luego se cuela por medio de desperdicios de algodón por el que se remueven las impurezas lijeras. Cada filtrador se provée con un lente fuerte de aumento para así poder inspeccionar la purificación del aceite.

Conductor de carbón en Washington. . . . [Pág. 744.]

El grabado enseña una vista del conductor de adonde las cenizas son tomadas de las páilas y conducidas al tanque de ellas. El túnel es de cerca 61 m de largo. El mismo balde conduce el carbón á las páilas.

Enganches automáticos para carros. . . . [Pág. 744.]

Los grabados enseñan dos tipos de una hechura de enganches para carros cuyos se usan prácticamente en todos los ferro carriles elevados de América y varios caminos de la superficie. Usanse, en la actualidad mas de 50000. Los enganches se usan tambien en muchas ciudades de Europa.

Nueva fábrica de una retranca de fuerza motríz. . [Pág. 747.]

Esta describe la nueva fábrica de una compañia que está haciendo grandes negocios en la fabricación de retrancas de aire para los carros urbanos. Toda la fuerza motríz es distribuida en toda la fábrica por electricidad ó aire comprimido.

Grandes productores de alambre. . . . . [Pág. 747.]

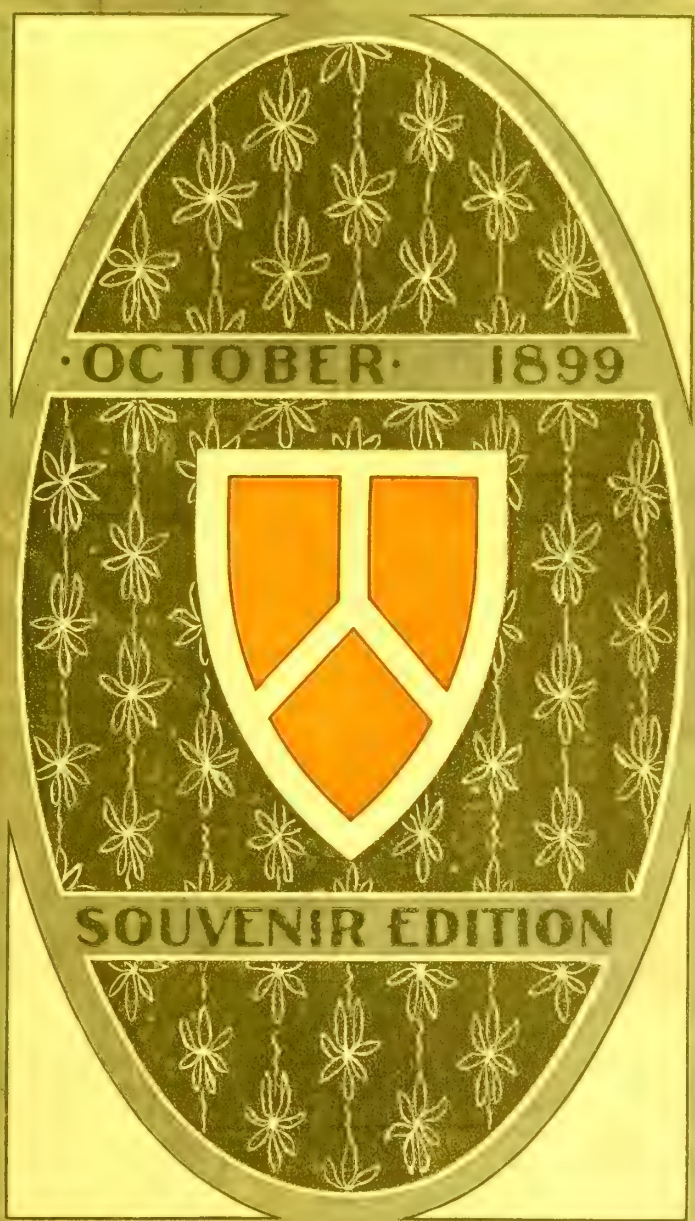
La compañia mencionada pretende tener la planta ó edificio individual mayor en existencia, para producir ambos, esto es, conductores eléctricos y cuerda de alambre. Se hacen toda clase de alambres.

Acumulación ó aire depositado para retrancar los carros. [Pág. 748.]

En este sistema el aire es comprimido en la estación de la fuerza motríz á cerca de 15 admósferas y es luego acumulado en depósitos en los carros. Antes de aplicarlo á las retrancas se pasa por medio de una válvula reducida la qué, á su vez, la comprime á cerca de tres admósferas. No se conduce ningun freno con tornillo de presión en el carro. La compañia que principió hace cerca de un año, ha equipado ya cerca de cuarenta y dos carros con resultados satisfactorios y reclama un número de ventajas para esta retranca.

Una gran casa inglesa de abastecimientos. . . [Pág. 748.]

Esta firma fué establecida en 1800 y negocia en toda clase de instrumentos medidores haciendo una especialidad para registrar los instrumentos requeridos en Inglaterra por la Junta de Comercio.



Algun trabajo eléctrico reciente en Inglaterra. . [Pág. 749.]

Este describe el trabajo de un expendedor bien conocido en aparatos eléctricos ferro-carrileros.

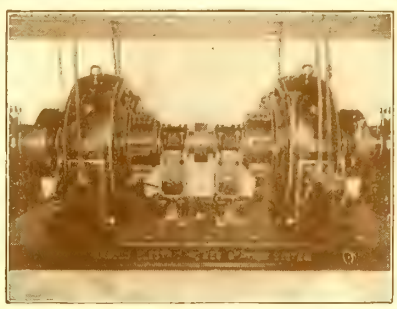
OUR RECORD.

The plants of the following companies were built from the designs of the president of this company while acting in the capacity of consulting engineer:



1893

COLUMBIAN INTRAMURAL RAILWAY

At the World's Fair.

The **FIRST** successful elevated electric road in the United States.

1895

CHICAGO BOARD OF TRADE.

The **FIRST** isolated plant to successfully operate arc lights, incandescent lamps, motors and electric elevators off one set of mains by means of a storage battery.

1896

ENGLEWOOD & CHICAGO ELECTRIC RAILWAY.

The **FIRST** successful storage battery road in the United States.

THIS COMPANY DESIGNED AND BUILT

1898

The power station of **THE IMPERIAL ELECTRIC LIGHT, HEAT AND POWER CO.,** of St. Louis.

The **FIRST** direct current central station in the United States to successfully operate incandescent lamps, arc lamps, 250 and 500 volt motors off one set of mains.

1898

The complete light, heat and power plant of the **CHICAGO GREAT-WESTERN RAILWAY COMPANY**

At Oelwein, Ia.

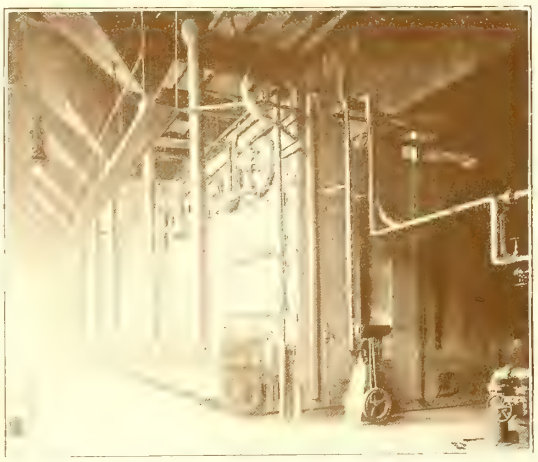
The **FIRST** plant to utilize magnetic clutches for connecting shafting.

1899

The entire equipment, excepting track of the **CHICAGO & MILWAUKEE ELECTRIC RAILWAY.**

The **FIRST** long distance electric railway operated from a central steam station using three-phase transmission, rotary converters, sub-stations and battery auxiliaries.

IN EACH OF THE PLANTS BUILT BY THIS COMPANY, A STIPULATED ECONOMY WAS GUARANTEED UNDER A BONUS AND FORFEITURE CONTRACT.



THIS COMPANY IS PREPARED TO SUBMIT PROPOSITIONS ON COMPLETE ELECTRIC PLANTS FOR ANY PURPOSE, UNDER RELIABLE GUARANTEES, AFTER LEARNING PARTICULARS.

W. Bayard Cutting, Walter G. Oakman, A. D. Juilliard, Henry W. Poor, Louis Fitzgerald. T. Jefferson Coolidge, Jr. Charles S. Fairchild, Gustav E. Kissel, Isaac N. Seligman, E. R. Chapman.

PHYSICAL AND ACCOUNTING EXAMINATIONS.

In addition to accounting examinations, the charter of The Audit Company of New York authorizes it to examine and report upon the physical condition and economy of operation, among others, of electric railways and illuminating companies. It also appraises the values of manufacturing and other plants.

Physical and accounting examinations combined afford a correct basis for corporation financing and for valuation of corporate securities or partnership interests.

Maryland Trust Co.

Cor. South and German Streets,
BALTIMORE.

Capital, = = = $1,500,000.
Surplus, = = = 1,500,000.

A Legal Depository for Court and Trust Funds.

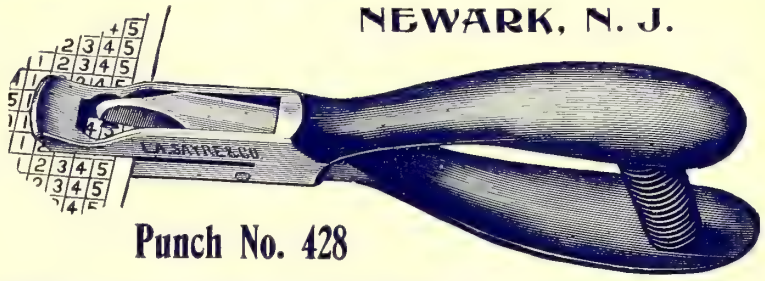
SAMSON SPOT CORD, WATER PROOFED.



For Arc Light and Trolley Cord.

Send for Samples. SAMSON CORDAGE WORKS, BOSTON, MASS.

L. A. SAYRE & CO.,

NEWARK, N. J.

The Best Punch ever made for Transfer Tickets.

Punch No. 428

Samples sent to railway companies on application.

LUBRICANT TRADE MARK REGISTERED.

Keystone Motor Grease.

The Following Official Reports have been Handed to Us:

Ten pounds of Keystone Motor Grease lasted a car for two months, which ran 8,205 miles. It took 28½ pounds of another grease (the best we could obtain), to last a car two months, which ran 6,100 miles.

ANOTHER REPORT:

Two and a half pounds of Keystone Motor Grease did better work that 12½ pounds of the best grease we could obtain, with no wear on sleeves wih Keystone, and just 1-16 inch wear with the other.

It Will do just as good Work for YOU. Send for SAMPLE CAN and Directions. NO CHARGE. Express PRE-PAID. CANNOT be obtained from Jobbing Trade Beware of those who say they have "JUST AS GOOD."

Mechanical, Electrical, Heating, Ventilating, Sanitary.

THE BALANCE-SHEET SYSTEM OF ACCOUNTS

Is Without a Rival in Utility and Economy

FOR USE BY

Street Railway Corporations, Manufacturing Establishments and Business Enterprises in General

It gives a GOING PROFIT and LOSS STATEMENT and a PERPETUAL Balance-Sheet

By the **Balance-Sheet System,** inventorying is rendered unnecessary, save only like counting cash, for the purpose of verification.

By the **Balance-Sheet System**, the laborious work of preparing statements of earnings and general condition, monthly, quarterly, and yearly, is avoided. The **Balance-Sheet Ledger** in plan and scope is a **statement in itself,** and is always up-to-date, ready for inspection. It keeps constantly before the management the results of the business in the exact form desired.

The users of the **Balance-Sheet System,** who at present are to be found in almost every part of the country, are its most enthusiastic advocates. They endorse and recommend it for its labor-saving features, its simplicity and its scientific accuracy. Their experience has conclusively demonstrated the advantages that it affords.

Installations are upon the Specification Plan. All instructions are in writing. Full particulars will be furnished upon request.

SPECIAL

TELEPHONES

.. FOR ..

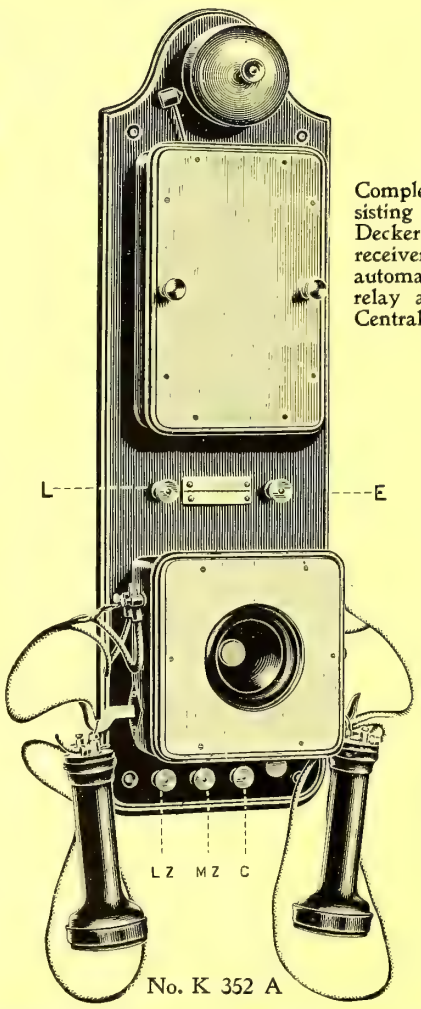
Electric Traction Systems

REGD No 339640

K 201

Complete instrument comprising cast brass case containing induction coil and line terminals, combined with hand combination with switch in handle for fixing in section pillars or other positions at intervals along tram or railway routes, so that car conductors can communicate with the Central Station in case of accident.

No batteries are required in the pillars.



REGD

K 202

Plug box only for fitting into pillars or other convenient position.

In this case the Telephone is carried on the car and is fitted with a plug. To communicate with the Central Station, the conductors simply insert the plug in the holes provided for the purpose, shown in illustration.

No. K 352 A

K 352 A

Complete Telephone consisting of Hunningscone-Deckert Microphone, two receivers, induction coil, automatic switch hook, relay and call bell for Central Station.

NOTE.—One set of batteries in the Central Station is sufficient for any number of sub-stations.

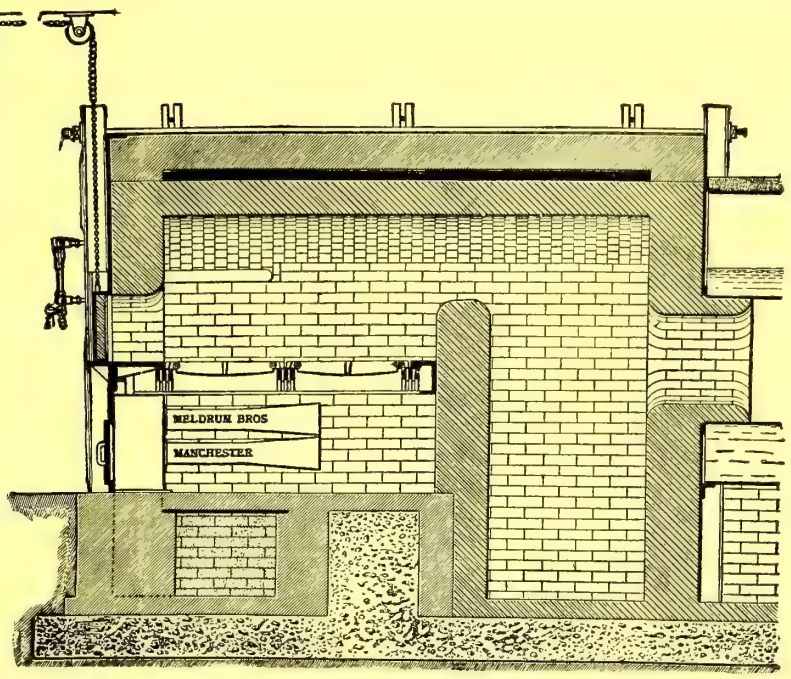
G. & J. WEIR, Ltd.,



THE LARGEST FEED PUMP WORKS IN EUROPE.

CATHCART, GLASGOW.

The Meldrum Patent Simplex

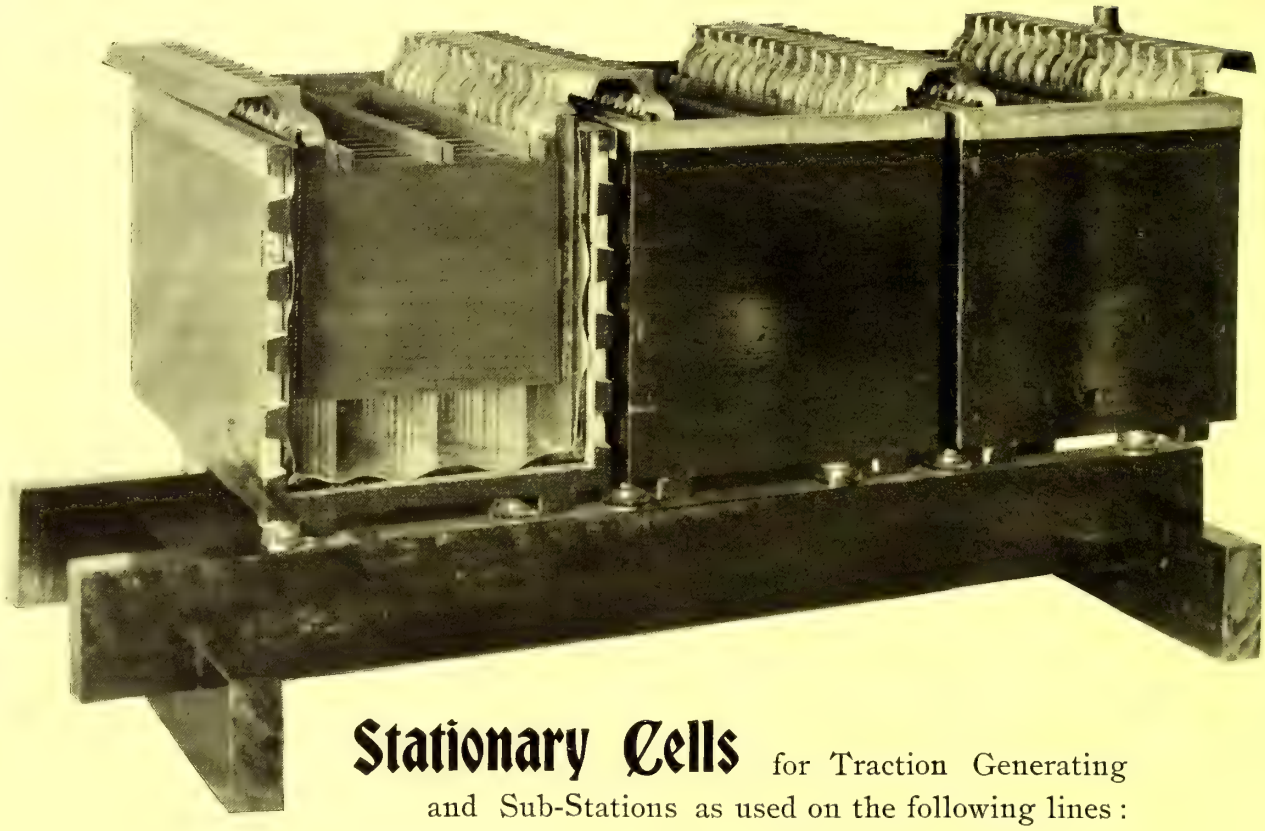
DESTRUCTOR

FOR BURNING TOWN'S REFUSE

The Utilization of Towns' or Colliery Refuse for some practical purpose has been successfully solved, and there is, therefore, no reason why every township should not have its own Electric Light Installation, and obtain all the power from its dust bins.

At Hereford City the Sewage Farm is now worked entirely with power from refuse, 1¼ million gallons being pumped per day, besides Sludge Presses, Sludge Pump, and Lime Mixers, the saving in cost of coal (not now used) being about £300 per annum.

ORDERS IN HAND FOR DARWIN ELEC. WORKS, BURTON, SHIPLEY, HUNSTANTON, BLACKBURN, &c., &c.



Write for full particulars, stating weight of refuse per annum, and for what purpose you would wish to use the power, when we shall be glad to submit a suitable scheme.

MELDRUM BROS.

Atlantic Works, Manchester, England

TUDOR ACCUMULATORS,

Specially Suited for Traction Work.

Stationary Cells for Traction Generating and Sub-Stations as used on the following lines:

Southampton Tramways.

DIE FALK COMPANY,

Milwaukee, Ver. Staaten v. Amerika.

WIR fabriziren erster Klasse Transmissionsräder und Triebel für elektrische Bahnen. Bahnen im Auslande laden wir speziell zur Korrespondenz ein und würden vorschlagen, uns Zeichnungen von Transmissionsrädern und Triebeln irgend welcher Art, wie sie von den Bahnen benutzt werden, zu übermitteln. Transmissionsräder und Triebel für sämtliche Normaltypen amerikanischer Motoren stets vorräthig. Auch fabriziren wir Oel-Sicherheits-Ausschalter für hohe Spannungen. Es ist dies die einzige Art Ausschalter im Markte, die sich bei Strömen von hoher Spannung ohne Bogen, Sprühen oder Gefahr verwenden lässt.

VGL. S. 150 UND 151.

LA FALK COMPANY

Milwaukee, E. U. de A.

MANUFACTURAMOS engranes y piñones de alta graduación para ferro-carriles eléctricos. Invitamos especial correspondencia de caminos estranjeros y sugerimos que nos envien dibujos de cualesquiera engranes y piñones que estén usando. De estos para tipos modelos de motores americanos los hay en existencia. Asimismo manufacturamos conmutadores de seguridad con alimentación de aceite para corrientes de alta potencia que es la única forma de conmutador en el mercado que puede manipular corrientes de alto voltage sin arco, chispa ó peligro.

VÉANSE PÁGINAS 150 Y 151

THE FALK COMPANY

Milwaukee, U. S. A.

NOUS manufacturons, pour railways électriques, des engrénages et des pignons de qualité supérieure. Nous invitons tout spécialement les compagnies de lignes étrangères à nous écrire et nous nous permettons de leur conseiller de nous envoyer les plans de n'importe quel pignon ou roue dentée dont elles se servent. Nous avons toujours en magasin des engrénages et pignons pour tous les types modèles de moteurs américains. Nous manufacturons également des commutateurs de sûreté, à interruption d'huile, pour des courants potentiels de haute intensité. C'est la seule forme de commutateur sur le marché qui puisse prendre soin de courants à voltage élevé sans arc, étincelle ou danger.

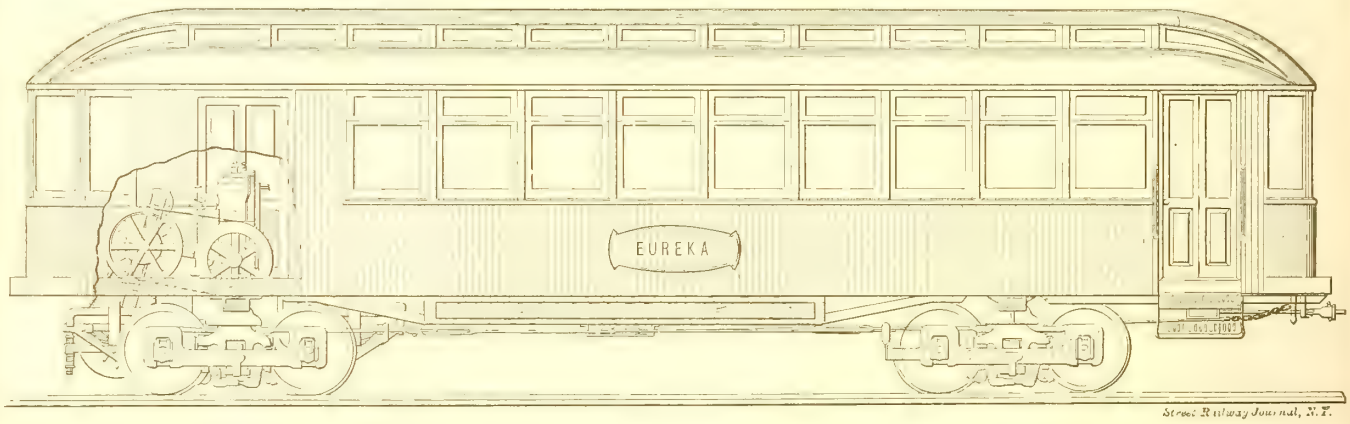
REASONS

why the HYDROCARBON MOTOR car is superior to all other methods for the propulsion of street and suburban cars:

FIRST—It can run on any track with any other system, and requires no trolleys or cables, no subterranean or overhead construction.



SECOND—It is the cheapest of all systems in cost of equipment and operation.

THIRD—Any accident to one car does not affect any other. The cars can run at any rate of speed and are started or stopped without jars or jerks. There is no noise or unpleasant sensation.

EIGHTH—They cannot be stalled on a railroad crossing in front of an approaching train by loss of power, as frequently happens with electric lines.

NINTH—There are no "deadly line wires," no breaking of cables, no failure of storage battery, no delays; each and every car runs independent and is always ready for use.

TENTH—They avoid all possibilities of accidents and deaths from "live" wires and standard cables.

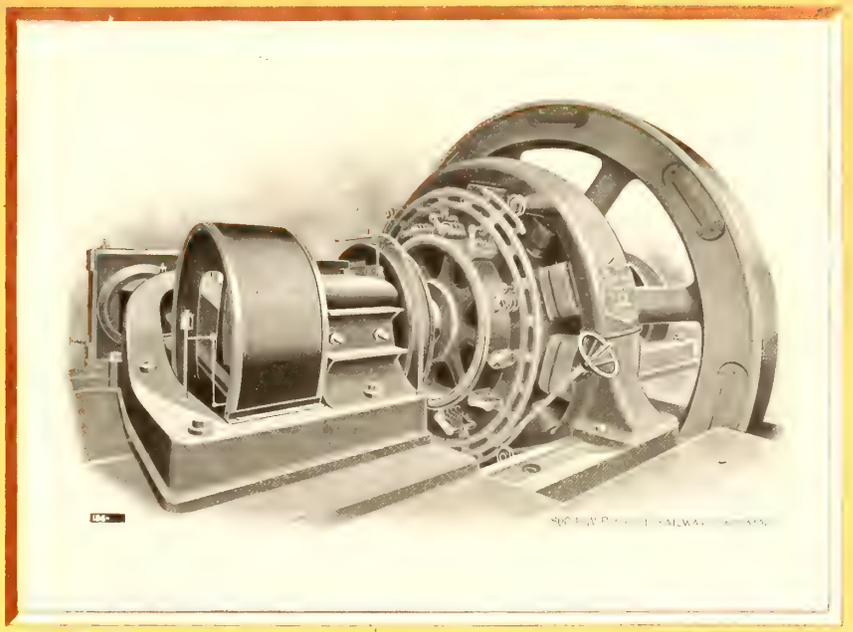
PLAN OF CAR NOW IN SUCCESSFUL OPERATION.

FOURTH—In operation it only requires a track and car barn.

FIFTH—The motors are all independent, so that no derangement of machinery at a central station can affect any car or cars on the line.

SIXTH—There are no dynamos or motors to be burned out or disabled during electric storms.

SEVENTH—Street blockades, or detention from any cause, cannot reduce the capacity for propulsion. The power remains intact until used, however long the period of suspension.



ELEVENTH—The motors are independent and not affected, as in other systems, by the derangement of feed wire or cable lines, broken station machinery, or by electric storms. In times of riot or other disorder, mischievous persons cannot obstruct the running of cars by tampering with the source or the conductors of power.

TWELFTH—That for the operation of city and suburban roads, whether surface or elevated, no other motive power can compare favorably with it, either in first cost, economy of operation, freedom from all objections, or the possession of incidental advantages.

FINANCIAL NOTES

INDIANA

The property and franchises of the Fort Wayne Consolidated Railway Company were sold at receiver's sale Sept. 28, to George A. Garretson, of Cleveland, for $1,092,000. Mr. Garretson represents the bondholders, and his offer was in excess of the appraised value, $564,000. The company will be reorganized and take in Frank de Haas Robinson, former owner of a majority of the stock.

The Indianapolis & Greenfield Rapid Transit Company has increased its capital stock from $1,000,000 to $3,000,000.

IOWA

The Sioux City Traction Company has filed with the Secretary of State an amendment to its articles of incorporation increasing the capital stock of the company from $1,000,000 to $1,200,000.

KENTUCKY

Middendorf, Oliver & Company, of Baltimore, offer for subscription an issue of $737,000 first mortgage, 5 per cent gold bonds of the Lexington Railway Company. The Continental Trust Company is trustee of the mortgage. The Lexington Railway Company is a consolidation of the Passenger & Belt Railway, Belt Line Electric Company, Central Electric Company and the Hercules Ice Company.

LOUISIANA

The New Orleans City Railroad Company reports earnings for

August	1898	1899
Gross receipts	$107,381	$113,410
Operating expenses	76,115	73,669
Earnings from operation	$31,266	$39,741

MINNESOTA

The St. Paul & Suburban Railway Company, of St. Paul, has filed a mortgage for $500,000 in favor of the Central Trust Company, of New York, to secure an issue of bonds.

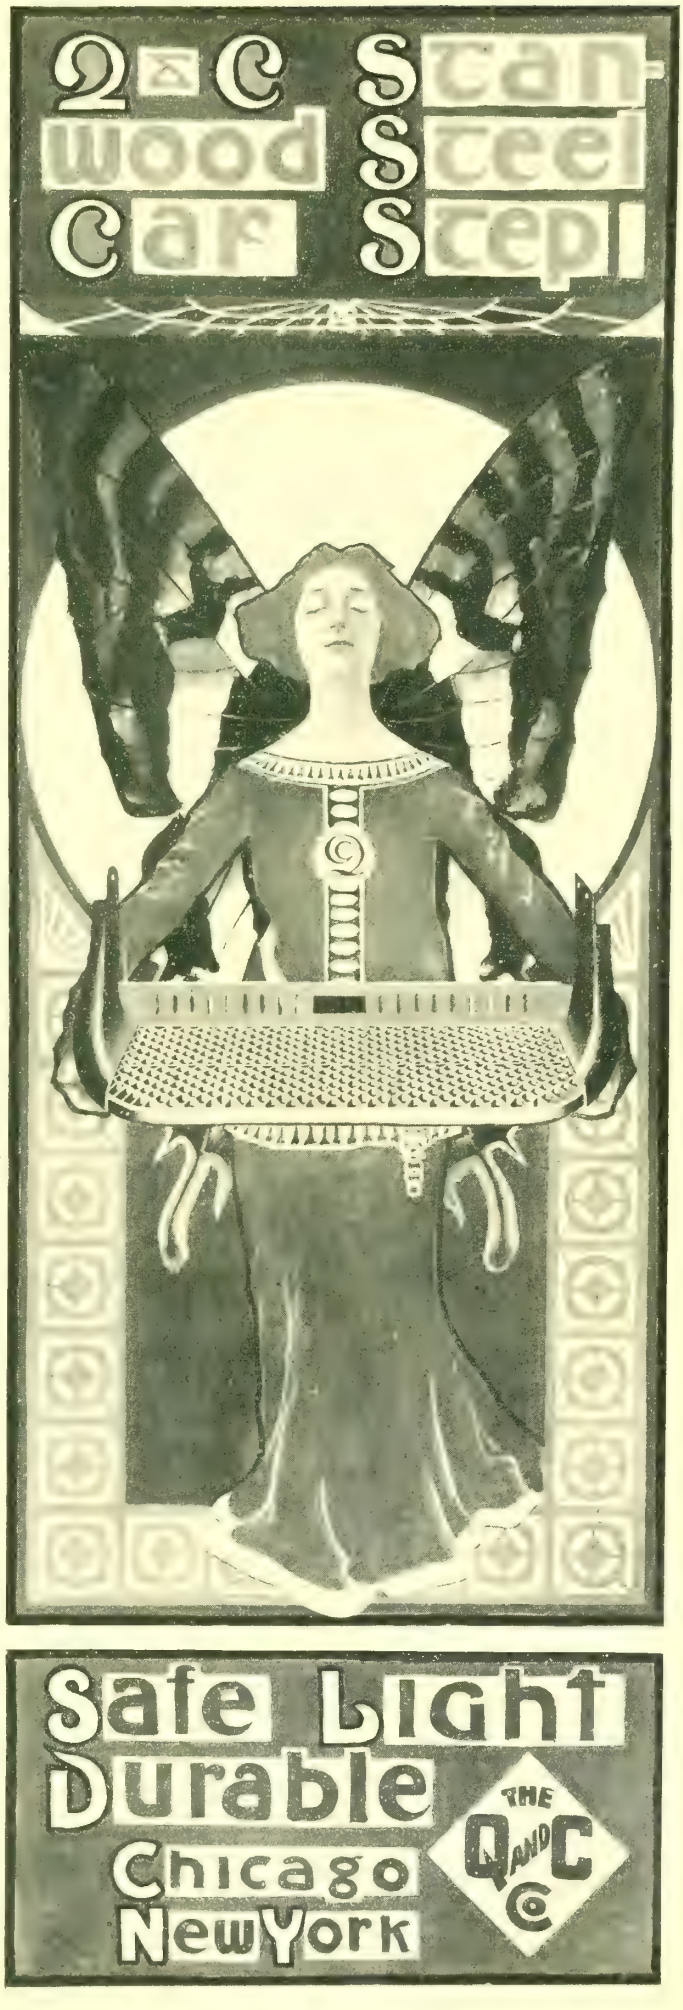
NEW JERSEY

The New Jersey Transportation & Elevator Company, which is building a monster elevator running from the Hackensack Plank Road, Weehawken, to the top of the bluff at Mountain Road, West Hoboken, at a cost of $100,000, has transferred its stock, placed at that amount, to the People's Elevator Company, controlled by the Shanley syndicate, which also controls the principal trolley roads in New Jersey. The elevator will be used for hoisting trolley cars, wagons and pedestrians to the top of the bluff, and it is rumored that the circuitous elevated trolley structure running from West Hoboken to Hoboken, is to be abandoned and a more direct line to the heights put in operation by running the cars to this elevator at Weehawken and there connecting with a new crosstown line to be built in West Hoboken.

NEW YORK

The property and franchises of the Middletown-Goshen Traction Company, of Middletown, have been sold at receiver's sale to Russell House, representing the bondholders, for $1 over the existing indebtedness of about $310,000. The property consists of 13 miles of electric road, operated through Middletown, Wallkill and Goshen, together with all buildings, cars, machinery and other appurtenances. Also the pleasure resort known as Midway Park, subject to leases, and a farm, of some 94 acres, adjoining. W. B. Royer, who has been acting as receiver of the company, will be made resident manager and treasurer of the company.

The Port Chester Street Railway Company has filed with the Secretary of State a certificate of the increase of its capital stock from $100,000 to $300,000.



The Metropolitan Street Railway Company, of New York, has declared a dividend of 1¾ per cent, payable Oct. 16.

The Brooklyn Rapid Transit Company has issued the following statement of its earnings for September:

Receipts from passengers.	1898	1899
Brooklyn Heights system	$535,330	$556,891
Nassau system	206,159	193,740
Elevated system	144,532	182,681
Receipts from other sources	26,670	28,912
Receipts total	$912,691	$962,224

Three months ending Sept. 30.

Receipts from passengers.	1898	1899
Brooklyn Heights system	$1,659,956	$1,651,470
Nassau system	684,871	570,595
Elevated system	420,974	534,872
Receipts from other sources	67,016	103,839
Receipts total	$2,832,817	$2,860,776

OHIO

S. M. Bullock, of New York, representing an Eastern syndicate, is said to have purchased the People's Electric Railway, of Sandusky, and the Sandusky, Milan & Norwalk Electric Railway, of Sandusky, for $140,000. The new company is known as the Sandusky, Milan & Norwalk Traction Company, and has filed a mortgage in favor of the State Trust Company, of New York, to secure an issue of $600,000 gold bonds, the proceeds of which will be used in betterments.

The Columbus Street Railway Company reports earnings for the week ending Sept. 28, as $15,108, against $13,272 for the same period of 1898, showing an increase of $1,836. The total increase in earnings since Sept. 1, 1899, over the same period of 1898, was $12,167.

The motion to set aside the sale of the Newark & Granville Electric Street Railway has been overruled. Notice has been given that the case will be appealed to the Circuit Court.

The Cincinnati, Newport & Covington Street Railway Company, of Cincinnati, reports the following excellent statement of its operation for the eight months ending Aug. 30.

	1898.	1899.
Gross receipts	$433,138	$464,410
Operating expenses	209,606	190,191
Gross earnings	223,532	274,219
Tolls, damages, taxes, etc.	107,596	99,239
Net earnings	$115,936	$174,980

The statement is especially worthy of note because of the marked decrease in the operating expenses for 1899 over those of 1898.

PENNSYLVANIA

The Schuylkill Valley Traction Company, of Norristown, has filed an equipment mortgage to the West End Title & Safe Deposit Company as trustee, to secure the issue of $100,000 fifty-year 5 per cent bonds.

The directors of the Harrisburg Traction Company have declared an extra dividend of 1 per cent. This increases the annual dividend to 5 per cent and demonstrates the growing value of the stock.

The United Traction Company, of Pittsburgh, reports gross earnings for August of $150,980; operating expenses, $64,910; net earnings, $86,070; fixed charges, $52,986; surplus, $33,084.

TENNESSEE

J. B. Harrison, of Knoxville, has opened negotiations with the owners of the Chattanooga Street Railway properties for their purchase by the Baltimore syndicate which has secured control of the street railway and the electric light properties of Nashville and Knoxville. The Chattanooga deal, it is understood, is to include the Chattanooga Electric Railway, the Chattanooga Rapid Transit Company, the Signal Mountain Electric Railway, and the Chattanooga Electric Light & Power Company. It is possible that the incline railways up Lookout Mountain may also be included. J. B. Scott, of Baltimore, is interested with Mr. Harrison. He was instrumental in making the deals in the other cities mentioned.

COMPRESSED AIR MOTOR COMPANY.

COMPRESSED AIR MOTORS

An Independent Motor, under quick control, noiseless, at reasonable cost, of high efficiency, free from danger and all objectionable features. The most economical system in cost of installation, operation and maintenance ever offered to the public. Thoroughly tested, both Winter and Summer, and endorsed by prominent engineers.

Cars in size and appearance the same as electric or cable cars, the floor being no higher from rail. No paying space occupied by the air storage or mechanism, all being placed under the car floor.

RUN AT ANY SPEED DESIRED. OVERCOME GRADES AND SHARP CURVES EASILY.
EQUIPPED WITH NOISELESS AIR BRAKES.

Can be recharged with air in less than two minutes, and constructed to run any desired distance. Motors and entire load spring supported. Cars can be introduced one at a time on the track of any railway, steam, electric, cable or horse. Cars of this type performed a daily service of 81½ miles each upon 125th Street, New York City, for one complete year, during which time they ran 32,159 miles, and carried 188,854 cash fares.

American Street Railway Investments

.. 1899 .. EDITION

THIS manual (commonly called the "STREET RAILWAY RED BOOK") is the oldest, the largest, and by far the most complete financial publication devoted exclusively to the street railway field, and has become the recognized authority among bankers, brokers, investers, manufacturers and street railway companies of the United States and Canada. It contains a mass of statistical information impossible to find in any other publication.

The "Red Book" is useful to street railway officials wishing to compare the expenses and receipts of their roads with those of other companies; to bankers and brokers dealing in investment securities, and to manufacturers doing business with street railway companies.

OUR STUDENTS SUCCEED

REPAIRMAN BECOMES FOREMAN.

I cannot say too much in praise of The International Correspondence Schools and the excellence of their Instruction Papers. They are very thorough, being not too hard, nor yet too easy, but just right, making it possible for any one to understand them. When I enrolled in the Electrical Engineering Course I was a repairer of electric cars. I advanced in succession to wireman, dynamo tender, general electrician, and am now electric shop foreman with the Brooklyn Rapid Transit Co. I am now finishing the balance of my Course, and can see advancement and prosperity ahead.—*H. Edward Keffer, Foreman, 376 Palmetto St., Brooklyn Borough, N. Y.*

LARGEST SCHOOL IN THE WORLD.

112,000 Students and Graduates, Sept. 1899. Fulfilment of every promise guaranteed by $1,500,000 Capital Paid In.

NINE ELECTRICAL COURSES.—Electrical Engineering; Electrical; Power and Lighting; Electric Railway; Electric Lighting; Telephony; Telegraphy; Wiring and Bell Work; Electric Mining. $10 to $70, in small monthly installments pays for A SALARY RAISING EDUCATION. Electrical instruction in charge of R. B. Williamson, formerly Professor of Electricity in Lehigh University. Write for circulars and local references to

Rates of Fare

Special rate of one and one-third fare on the certificate plan has been made, and delegates, when purchasing tickets, should ask Ticket Agent for certificate, which, on presentation at Chicago, will secure one-third fare for the return trip. Sleeping car fares at regular rates.

The Committee in charge would respectfully urge all who take the special train at New York, or Stations on the New York Central & Hudson River Railroad to communicate with Milton C. Roach, General Eastern Passenger Agent, New York Central & Hudson River Railroad, 413 Broadway, New York, stating exact accommodations required and from what point.

Those who will take the train at Boston and Stations on the Boston & Albany Railroad should communicate with Mr. J. L. White, Passenger Agent, Boston & Albany Railroad, 266 Washington St., Boston.

Reservations will be made in order as received, and prompt notification of assignment made to applicant.

The Committee would respectfully suggest that delegates and their friends should make early arrangements. Applicants should address or call on Ticket Agent, L. S. & M. S. R. R., 180 Clark St., Chicago, Ill., for the return trip.

CONVENTION AT CHICAGO.

The WABASH RAILROAD, with its various lines running into CHICAGO from different sections of the country offers the best possible train service to members of the AMERICAN STREET RAILWAY ASSOCIATION who are going to attend their ANNUAL CONVENTION, October 17–20.

Direct connections made at ST. LOUIS and KANSAS CITY with all lines from the SOUTH and WEST, and through Sleeping Car Service from these cities to CHICAGO.

Direct connections at BUFFALO with all lines from the EAST, and through Sleeping Car Service from that city to CHICAGO.

Through Palace Sleeping Cars from BOSTON and NEW YORK to CHICAGO.

Special Round Trip rate of a fare and a third, on the certificate plan, has been granted by the various Railroad Committees for this event.

For information in regard to rates, train service, reservation of sleeping car space, etc., apply to your local ticket agent, or

CLEAN CARS—— PROMOTE TRAFFIC

TRADE MARK

The only practical, economical and efficient Car Cleaner on the market, and the one which is at present employed by over four-fifths of the steam railroads of the country is the ...

MODOC LIQUID CAR CLEANER

It is a thorough cleaner and varnish feeder, giving the highest possible lustre, which it retains. It avoids the use of soap and water, and by preserving the varnishes, will prolong the life of your cars, and save much of your present expense for repainting and revarnishing.

MODOC POWDERED SOAP

is the recognized standard for the thorough cleaning of cars in shops before revarnishing.

Full information regarding both Cleaner and Soap, with directions for use and samples, will be furnished free on application to **THE MODOC SOAP CO., CINCINNATI, O.**

JAPAN-AMERICAN

COMMERCIAL AND INDUSTRIAL ASSOCIATION,
SHIZUO KONDO, President.

HEAD OFFICES:

Tokyo, Japan. Singer Building, Broadway and Liberty St, New York.

Owing to the remarkable increase of trade between United States and the Orient, the Association has greatly extended its facilities for serving subscribers.

These services now include commercial ratings of concerns transacting business in Japan, Formosa, Korea, China, Straits Settlements, Philippines and Hawaii; accurate lists of names and addresses engaged in any trade or trades in any or all of said countries; selling connections for your products with responsible houses under open or exclusive agreements; patents, copyrights and protection of trade marks; lowest freight rates and attention to shipments; translation of all correspondence both ways; special commercial and industrial information together with a copy of the Japan-American Commercial Journal and other publications, published under the auspices of the Association in Tokio.

The annual registration fee entitling to the above services, with no additional charges, is twenty-five dollars. The Association refers to many subscribers who have received important benefits.

Manufacturers, merchants, shippers and others interested in originating or increasing trade with Japan and the Orient will receive explanatory documents and a copy of the Japan-American Journal, the organ of the Association, published in English and Japanese, upon application to

CHARLES E. LOCKE, Director for United States,
SINGER BUILDING, NEW YORK.

IT SAVES 50% OF ICE

and keeps the water at a cold spring water temperature....

Major's Ice Receptacle

is made to fit any Cooler. It has a dead air space around it, and the cover is also double.

The water flows into the Cooler through holes an inch above the bottom of Receptacle.

Any Cooler in which the Receptacle is placed will not sweat. The Cooler and the water on the outside of the Receptacle are kept from getting *extremely and unnecessarily* cold, and the ice therefore melts half as fast.

The Cooler need not be replenished with ice as often, thereby saving labor. It protects the Cooler, and by furnishing water at the proper temperature the injurious effects of drinking ice cold water are avoided. When inquiring always give inside measurement of your Cooler. I can furnish different makes of Coolers at the lowest prices if desired. Address

A. MAJOR, 461 Pearl St., N. Y.

Do You Know What Your Output is Costing You?

The PROOF-BY-BALANCE SYSTEM OF COST ACCOUNTS, which for several years past has formed an important feature of various specifications of the BALANCE-SHEET SYSTEM OF ACCOUNTS, is now offered to manufacturers generally.

It is suited to every line of business and to every class of product. The principles are unvarying, but their application differs from time to time. Adaptations are always intelligently made to meet requirements.

The leading features of the system include the following :—

1. The cost value of materials on hand, in gross and in as many subdivisions as may be desired, is shown at all times.
2. The cost value of work in progress, in gross and in whatever detail is required, is indicated at all times.
3. The cost value of goods completed and on hand, in gross and in as fine detail as desired, is shown at all times.
4. The correctness of the figured cost of goods is proven monthly by balancing with total charges to factory.
5. The constant employed for spreading over product the general expenses of factory is corrected monthly in the light of actual facts thus adjusting recorded costs to conditions of output.
6. Inventorying is reduced to the examination of individual departments or classes of materials to verify the corresponding accounts

The cheapest system to install and maintain, and the most efficient and satisfactory in use.

Installations are made upon the Specification Plan exclusively. Everything is in writing. No oral instruction.

No changes in your present system until you have had a chance to study the new, and make sure that all its details please you.

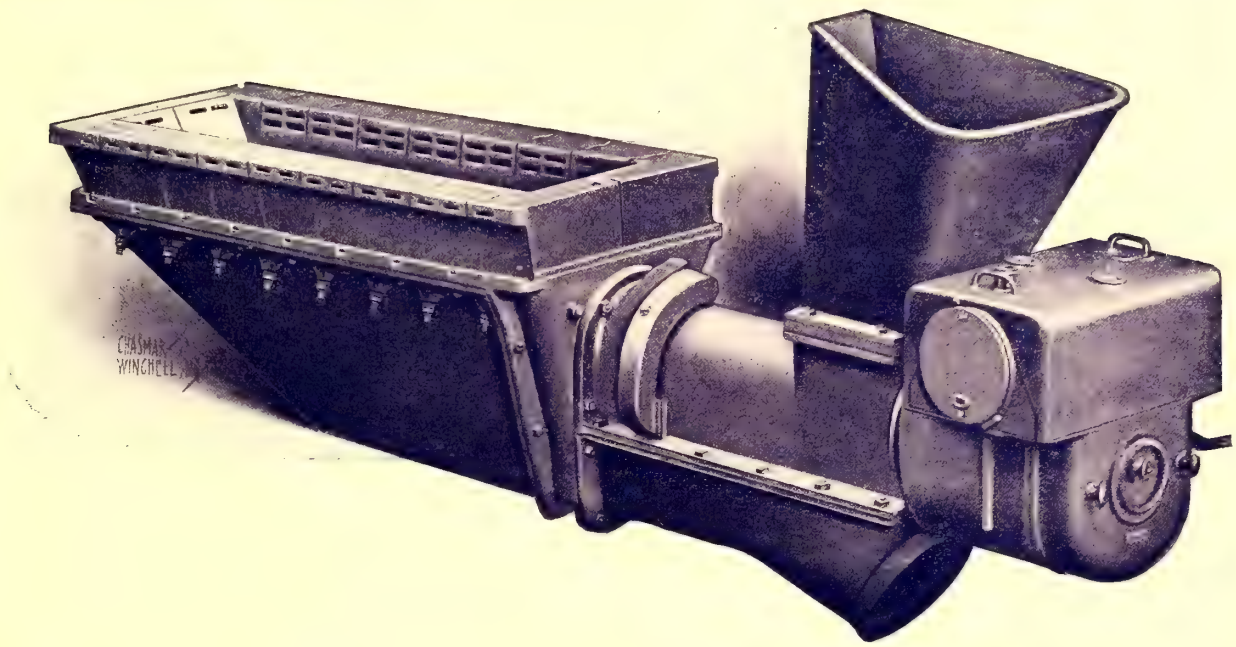
THE AMERICAN STOKER

IN ACTUAL PRACTICE HAS PROVEN TO BE A MOST REMARKABLE

Smoke Preventing and Fuel Economizing Device.



Maximum Efficiency and Economy.

The Union Station of the Edison Electric Light Co. of Brooklyn, have an installation of **fifteen** under "Cahall B. & W. Type Boilers" and have ordered **twenty-one** more.

The Hunt Power Station of the Cincinnati Street Railway Co. have installed **twelve** under "Abendroth & Root Boilers."

The Carnegie Steel Co. have at present in operation **fifty-eight** of these Stokers under "Two Flue Boilers," we having just completed an installation of **twenty-eight**.

The Kings County Electric Heat and Power Co. of Brooklyn, N. Y., have an installation of **eighteen** under "Stirling Boilers."

The Schoenberger Steel Co. gave us several orders, aggregating **eighteen** Stokers prior to January 1, 1899. This was followed by an order for **twenty** more. Since then, **thirteen** more have been installed, and we have an order now for **twelve** additional for them.

The Akron Street Railway & Illuminating Co. write as follows: "We have had in use four of your Stokers for about a year and one-half. We think there is nothing that we have had in service in the stoker line that comes anywhere near being as economical and reliable as they are. We are now about to install twelve more, which fact alone speaks for itself; eight of these are taking the place of other automatic stokers."

THE "AMERICAN" WORKS WITH ANY TYPE OF BOILER.

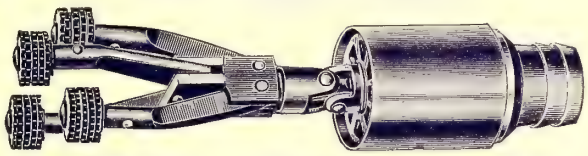
—THE—



UNION BOILER TUBE CLEANER COMPANY

240 Penn Avenue **Pittsburgh, Pa.**

Has set the acknowledged standard of the World for removing—by **POWER**-driven **MECHANICAL** devices—all conditions of scale from all makes of Water Tube Boilers—curved as well as straight tubes—also from pipes and tubes used in industrial enterprises. We have the only

FLEXIBLE SHAFT OF REMARKABLE STRENGTH AND PHENOMINAL DURABILITY UNDER GREAT STRESS

Not an "Impulse" Cleaner.

Our **TURBINE CLEANER** develops five times as much power and will remove scale upon which an "Impulse" cleaner makes no impression. Hundreds in use by the best firms in America. Sent anywhere on approval.

We clean boilers by contract, or lease or sell Power-Driven Cleaners at one-fourth usual prices. We analyse feed waters and supply compounds guaranteed to loosen scale and prevent its re-formation.

If you will write us particulars, we will agree to remove your scale by the most economical process.

CHICAGO BOILER CLEANER CO., 262 Dearborn Street, CHICAGO. ILL.

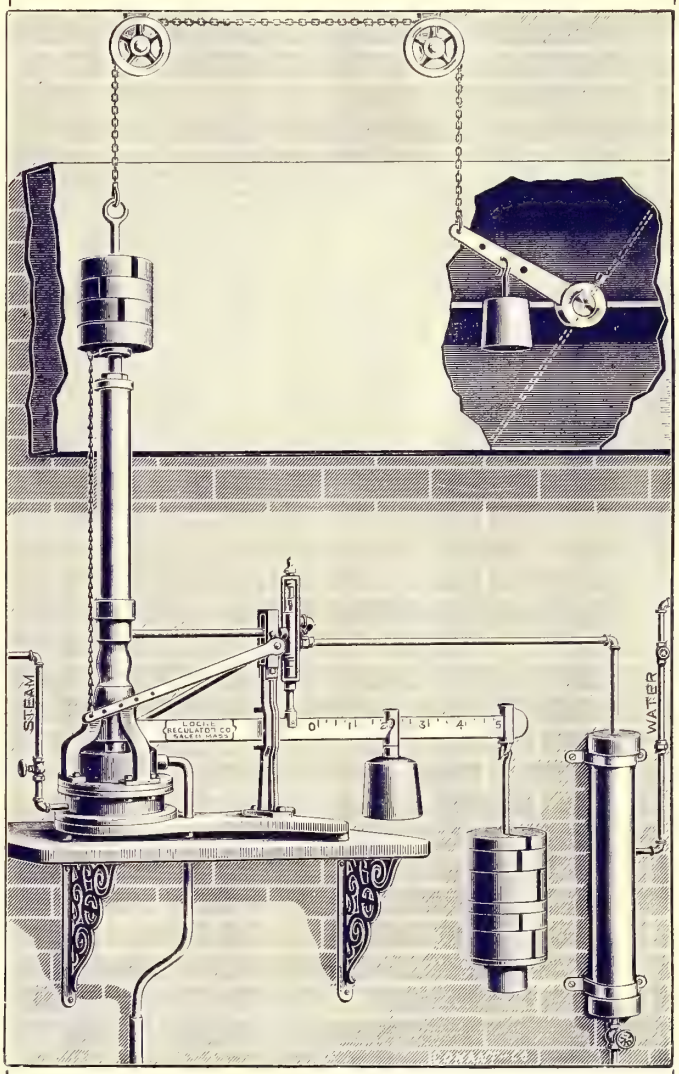
Working Drawings of Electrical Apparatus.

By Prof. E. ARNOLD.

Two Portfolios, 16 x 21 ins. **Price, each Portfolio, $5.00.**

Portfolio I.—**Direct Current.** 64 sheets of working drawings of ring and drum armatures, commutators, brushholders, field frames, bearings, etc.; designs of dynamos and motors ranging from 16 K. W. to 620 K. W.; street railway motors; arc light generators.

Portfolio II.—**Alternating Current** 48 sheets of working drawings of single-phase, two-phase and three-phase generators from 7 K. W. to 1600 K. W.; single-phase and poly-phase synchronous and induction motors from ¾ H. P. to 150 H. P; single-phase and poly-phase transformers from 10 K W. to 150 K. W.; pole construction and other details.



Among the twenty or more European manufacturers represented in this collection of dimensioned drawings are the Oerlikon Works; Brown, Boveri & Co.; Allgemeine Electricitats Gesellschaft; Alioth; Farcot; Schuckert & Co.; Siemens & Halske; Lahmeyer & Co ; Ganz & Co.; Kolben & Co.; J. J. Rieter & Co , etc.

By a special arrangement with the German publishers of this valuable collection of working drawings, subscriptions will be received until September 15th at the German price of 20 marks=$5 00 per portfolio. The portfolios may be had singly. Delivery will be made by October 15.

Street Railway Publishing Co.,

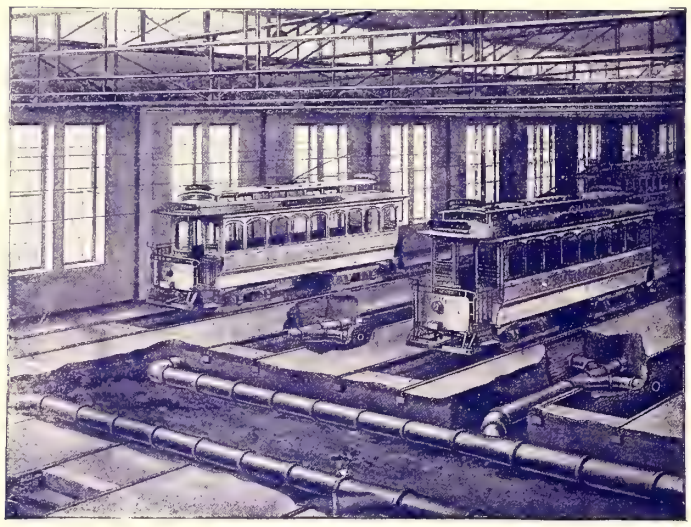
Locke's Graduated Hydraulic Damper Regulator

This Great Coal and Labor-saving Device stands at the head of all devices for controlling the consumption of fuel. Is used in all large steam plants.

Guaranteed to perfectly control the heaviest dampers and to operate on the slightest change of pressure. Is worth many times its cost and will last as long as the boilers.

Over 6,000 in use

Beware of infringements. Any regulator having the essential features of this machine and especially those with the graduated scale beam are direct infringements of the Locke patents. The users of such machines will be held strictly accountable to this company. All genuine Locke Damper Regulators have a plate bearing the dates of the Locke patents.



GENUINE LOCKE MACHINES ARE SOLD AT A VERY MODERATE PRICE :: ::

IN ONE-THIRD THE TIME

NUMEROUS CAR BARNS IN THE UNITED STATES AND CANADA HAVE THE PITS SUPPLIED WITH HOT AIR BY THE STURTEVANT SYSTEM AS ABOVE. WE SOLICIT AN OPPORTUNITY TO TELL YOU MORE ABOUT IT.

the snow and ice can be melted from car trucks and motors when the

STURTEVANT SYSTEM

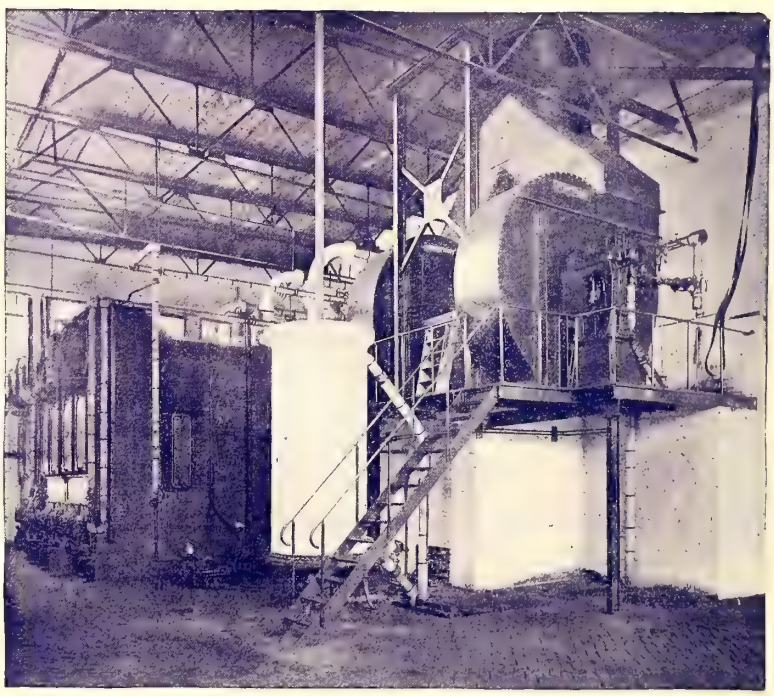
IS USED.....

It also heats the car barn thoroughly. A forced circulation of hot air does it.

There is no extended steam piping system with danger of leakage and freezing. Just a blower and a steam coil; that's all. It will heat anything.

Sudden Demands for More Steam

CAN BE INSTANTLY MET WHEN



Mechanical Draft

Is employed. It responds instantly, and is always positive. The weather makes no difference.

Saves two-thirds the cost of a chimney.

Decreases the coal bill by burning low grade fuel.

Has many other advantages.

CONVENTION REPORT NUMBER

A VERBATIM REPORT of the Proceedings of the Chicago Convention of the American Street Railway Association will be published in the November issue of the STREET RAILWAY JOURNAL. This will include the papers read, discussions on same, reports of committees, illustrated descriptions of exhibits, etc. The value of this matter to everyone interested in modern methods of electric railway construction and operation, will cause the November Number to be read with great care, and to be referred to for a long time to come. Its value as an advertising medium is evident .. .. ..

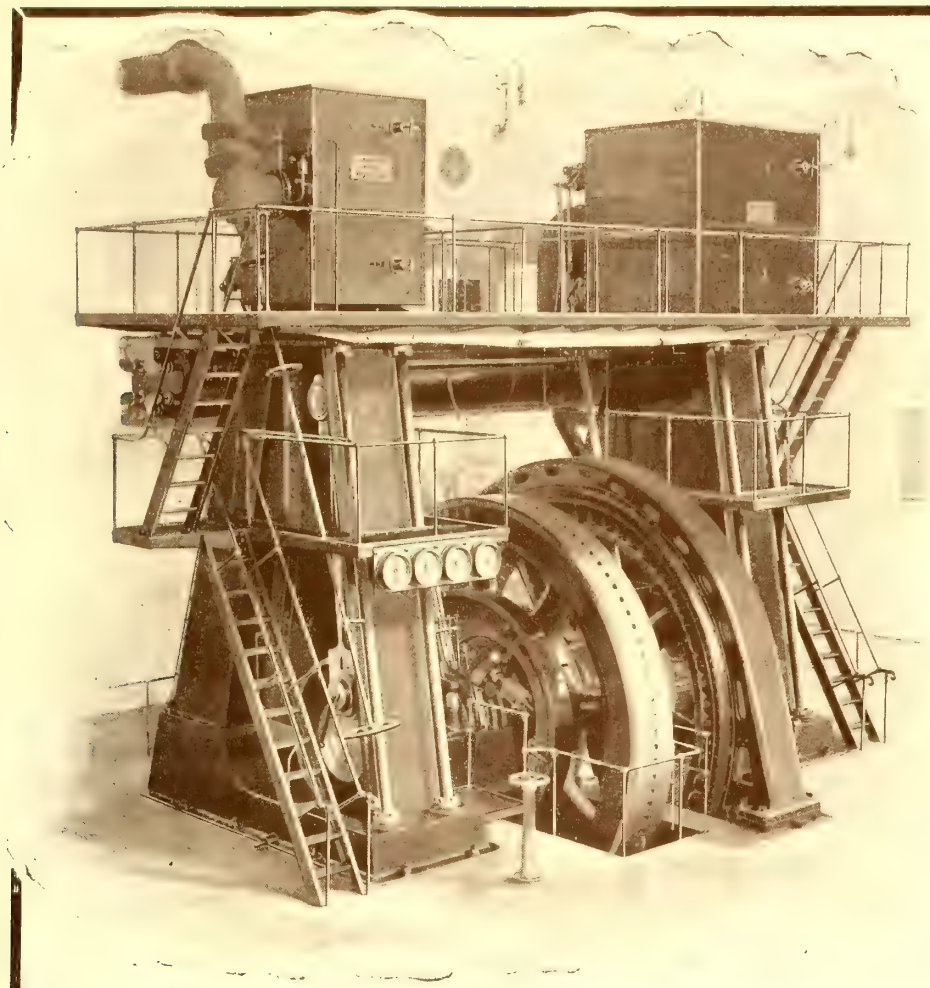
STREET RAILWAY JOURNAL

Providence Engineering ...Works...

PROVIDENCE, R. I.

Sole Builders of Rice & Sargent and Improved Greene Engines.

These engines lead in results obtained on railway and electric light work, with direct and alternating current. Special attention is given to the operation of alternating current generators in parallel.



The Regulation of our engines is unequalled.

Speeds as desired, from 80 to 150 revolutions per minute.

Reference is made to the large number of plants installed by us, which are the best testimonials of the economical and regular working of these engines.

The limit system of construction is used throughout.

We lead in design, workmanship and materials.

Duplex Compound Engine

and Direct-Connected Generator

A Compound Engine specially adapted to non-condensing railway service.

A clear saving of 25 per cent. in fuel under all conditions of load.

Requires no more floor space than a simple engine, no more cost of attendance or repairs.

We furnish complete direct-connected plants, both engine and generator of our own manufacture.

LUBRICATION

The durability and good service of machinery depends, to a great extent, on the lubrication. The best constructed and most perfect machine may be seriously damaged or utterly ruined by neglect or imperfect lubrication. We have invented and patented a Perfect System of Automatic Lubrication, known as the SIEGRIST AUTOMATIC OILING SYSTEM.

In this system the lubrication is effected by the installation of the Siegrist Automatic Oiling Table, the required number of Siegrist Pressure Oil Cups and Siegrist Sight Feed Lubricators, also a first-class filter to filter the engine oil as it is returned from the bearings and working parts of the engine, thereby making a combination that cannot be surpassed as an investment for the saving of oil, and the displacement of the large number of men now required in the modern power plants to keep the multitude of oil cups filled and to carry the oil from engine to engine, all of which is displaced by the installation of our Automatic System. Send for Circular and full information.

Coal Handling in Power Stations

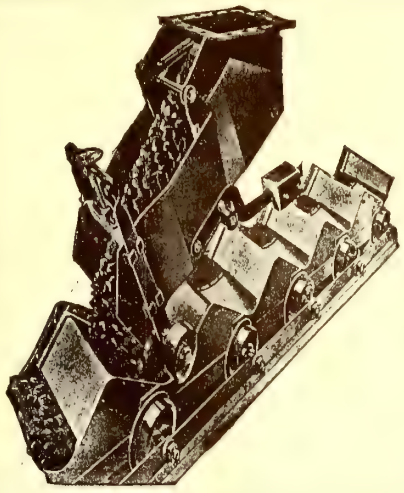
Coal and Ash Handling Machinery Installed for the Detroit Citizens' Railway, Detroit, Mich.

In order that the operating expenses be reduced to a minimum, the station is fitted with a complete system of coal and ashes handling machinery. The coal is delivered from the railroad cars into the hopper shown in above cut, from which it is drawn into the conveyor, which carries the coal to the storage pocket, holding 1,000 tons, from which it is drawn to the stokers. The conveyor passes under the floor of the boiler room, and carries the ashes from the hopper under the boilers to the ash storage, from which they can be removed at will.

We have spent 27 years minimizing the cost of coal handling.

Our machinery for this purpose is in use in almost every city and port in America and in almost every country in the world.

We build "Industrial," Cable and Automatic Railways; Steam and Electric Hoisting Engines; Coal Crackers; Hunt Noiseless Gravity Conveyors, etc.



We will be pleased to correspond with those about to erect new or to revise their present plants.

HUNT

C. W. HUNT COMPANY

Elm Street, WEST NEW BRIGHTON

STATEN ISLAND, N. Y.

LINK-BELT COAL CARRIER

One of the interesting features of the "Link-Belt" Carrier is the Automatic Feeding Chute, shown by illustration. This device does not overfeed, underfeed or require attention. It is adjustable to all sizes and kinds of coal.

We have machines for the handling of any material under any conditions.

No one design is best for all, though the "Link-Belt" Carrier is the right solution for many of the Coal and Ashes handling problems at Electric Railway Stations and Power Houses. We will show you some of its other details later, and, if you wish, will be glad to mail you copy of our Carrier booklet.

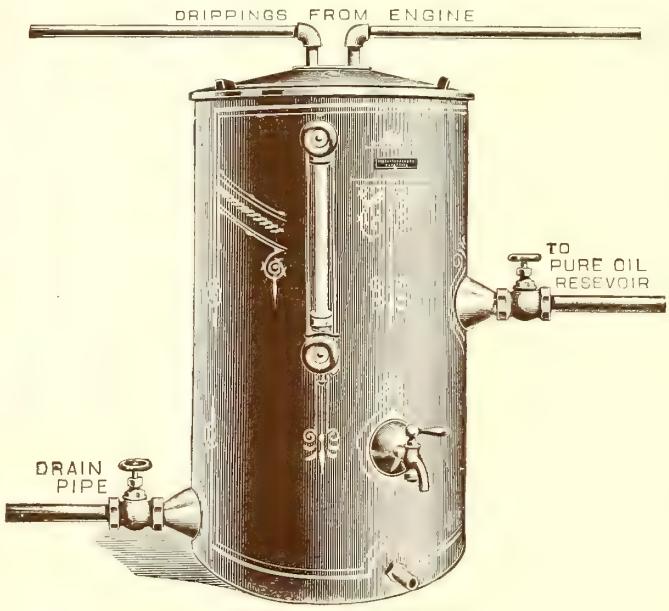
THE "99" FAMOUS WASTE OIL REFINER AND PURIFIER

is not a water-using fallacy, nor is it merely a strainer or settling tank.

By the correct application of HOT AIR (a new discovery) the Famous extracts the minute carbon and other suspended impurities. These injurious impurities are so minute that they readily pass through ANY kind of waste oil filtering material with the oil.

Capacities, 5, 10, 20, 40, 75, 150 and 300 Gallons Per Day

For full description, etc., of this modern device, address



THE FAMOUS FILTER CO

316 NORTH MAIN STREET, - ST. LOUIS, MO.

...Gravity... Oiling System

❧❧❧During the past year or so, we have placed a great many of our Oiling Systems into some of the largest power plants, both here and abroad. This System insures neatness, cleanliness and economy in oil handling. The costs of installations are so trifling that the savings effected very quickly pay for the installation. Our Filters have been on the market nearly 10 years, are used in 24 countries, and have been adopted by 4 governments.

❧❧❧We manufacture a complete line of Oil Filters, from 3 to 150 gallons filtering capacity per day, to use with or without our Oiling System. We can equip the largest as well as the smallest power plant.

(PATENT APPLIED FOR)

THE BURT MFG. CO.

Dear Sirs:—You asked us some time ago to obtain for you some information about the two 120-gallon Filters we purchased. They were for the installation we were putting in, to be used at the Moutreal Street Railway Power Works of this city. We are in a position to report further, that they are working very satisfactorily, in fact much better than they anticipated. You may use this for any medium of advertising you may desire.

Trusting our report will be appreciated by you.

Yours truly,
LAURIE ENGINE CO.

CAPITAL TRACTION COMPANY
WASHINGTON, D. C.

August 4th, 1899

THE BURT MFG. CO.

Gentlemen:—Answering your inquiry of July 29th, I am pleased to state that the two 80-gallon Cross Oil Filters and Purifiers which our company purchased from you have been in use for sixteen months, and have given perfect results and much satisfaction. I have no hesitancy in recommending its use to all requiring a perfect filter.

Yours truly,
C. HOSHALL,
Engineer Grace St. Power Station, Capital Traction Company, Washington, D. C.

...OIL TANKS...

❧❧❧We also manufacture a complete line of Oil Tanks to use with our Oiling System or for other purposes. We can furnish any capacity desired made out of galvanized iron, brass, copper or sheet iron.

Upon application, we will be pleased to quote prices, send catalogues, list of users, testimonials, etc.

SEND FOR OUR CATALOGUE... CHICAGO OFFICE: 1105 Monadnock Block

... AMERICAN ...

ECONOMIZER

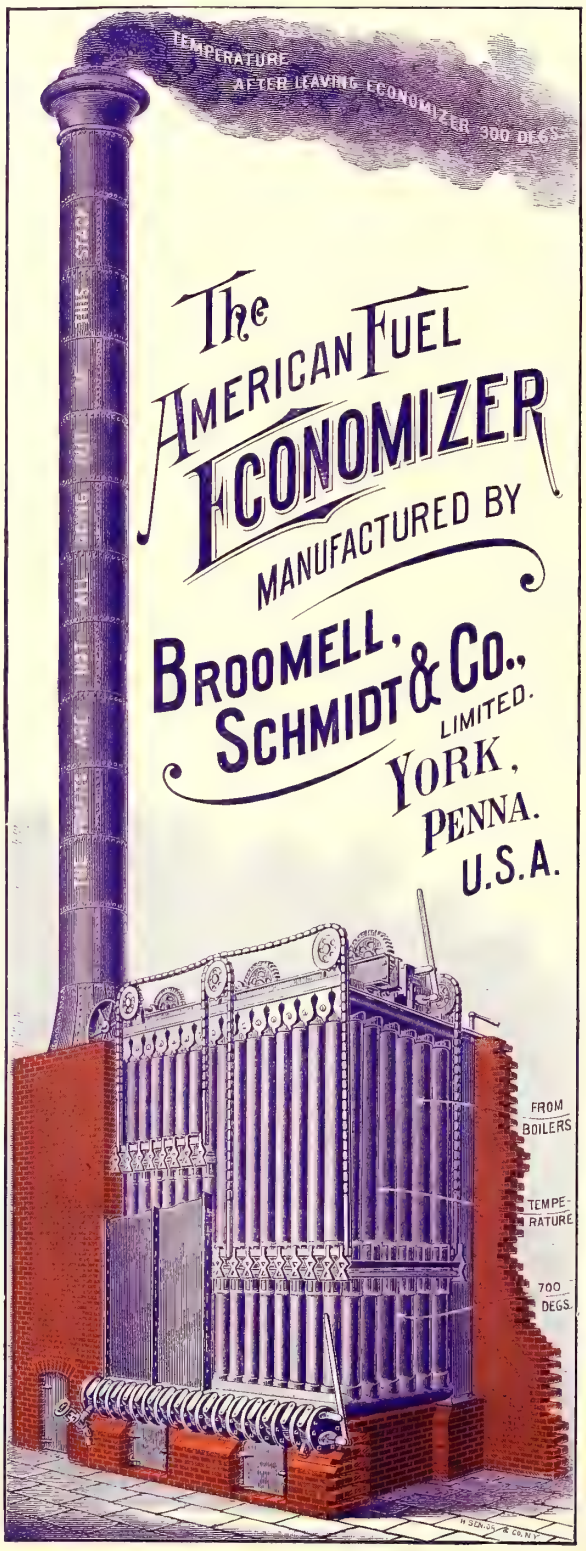
(BURPEE'S PATENTS)
(BROOMELL'S PATENTS)

FOR HEATING AND PURIFYING FEED WATER FOR STEAM BOILERS
BY UTILIZING THE HEAT IN FLUE GASES

Mechanical Draft...

THE ideal steam plant of the future will be arranged on the induced draft system. The smoke fans will be built in the best possible manner and of ample capacity to handle the gases at a very low rate of speed. The engines attached to these fans will be strong and heavy, arranged to use steam in the most economical manner, and will be automatically regulated to the draft required.

American Fuel Economizers of ample proportions will be installed between the boilers and the smoke fans. These Economizers will be enclosed in the most approved style of sectional metallic casing.



The boilers will be equipped with the latest pattern of mechanical stokers and smokeless furnaces, the whole making a complete and satisfactory plant which will produce steam at a cost below that on any other system

We are prepared to install induced draft systems and to guarantee all the above desirable results. We build our own engines and smoke fans, which are carefully designed and built in the very best possible manner from heavy steel plates strongly braced with angle and T irons.

We also recommend induced draft fans of very ample proportions. Mistakes that have been made on this system all come from using badly designed fans of entirely inadequate proportions.

Send full particulars, and will be glad to make plans and specifications.

BROOMELL, SCHMIDT CO.
(LIMITED)
YORK, PA.

American Fuel Economizer...

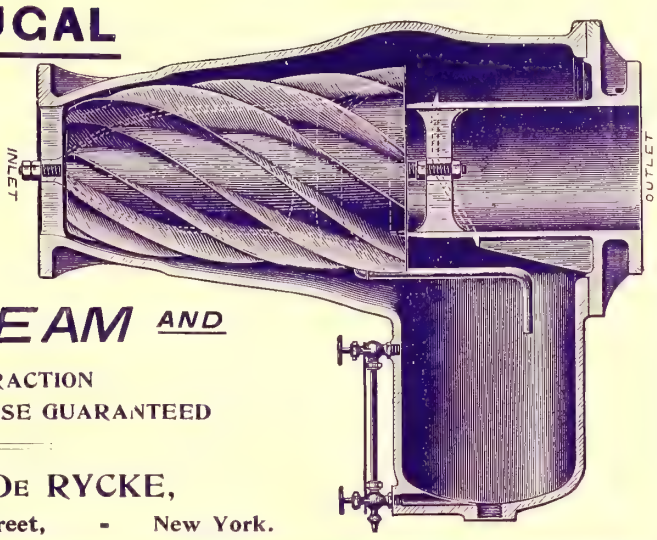
IF AN **American Economizer** is installed in your boiler plant, the results will be highly satisfactory for the following reasons:

1st. There will be an actual and genuine saving of fuel of from 10 to 25 per cent., which would otherwise be lost entirely.

2nd. There will be an increase in the capacity of your boiler plant, oftentimes sufficient to save investment in additional boilers.

3rd. There will be a great saving in the matter of boiler repairs, because the very hot water freed from impurities fed to the boiler prevents unequal expansion and accumulation of mud and scale.

4th. There will be less necessity to renew boilers, their lives being prolonged for the reasons given above.



5th. There will be less necessity to shut down for cleaning boilers, because the impurities contained in the feed water are precipitated in the Economizer in place of the boiler. The slow movement of water through the Economizer gives the time required to accomplish this result.

6th. There will be a great improvement in the matter of steam pressure because of the large amount of very hot water contained in the Economizer, which is always ready to draw on in case of a sudden call for steam.

7th. There are very many uses for hot water in manufacturing plants other than for feeding boilers. Packing houses use the water for many purposes; sugar refineries find continued calls for large quantities of hot water; dye houses and bleachers use hot water continually. Mills or factories can be heated by the circulation of hot water drawn from Economizers without any cost whatever.

We can also Refer to Many of the Largest Lighting Plants Throughout this Country and Europe

Why a Feed-Water Heater is Important.

Because for every 10° added to the temperature of the water before it enters a boiler about 1% of the total fuel otherwise required will be saved.

The theoretical saving is under one per cent. The actual saving, as demonstrated by numerous tests, both in this country and in Europe, ranges as high as one and four-tenths (1.4) per cent., with 1.2 as a fair average.

This means that if your initial supply (the cold water from your main, well, pond, or other source), has a temperature of 50° F. all the year round, you can, with exhaust steam at atmospheric pressure, heat this water to, say, 210° F.—a difference of 160°—and the saving will be from 16% up to 22%, with 19% as the average.

The Cochrane Heaters are noted for giving the full value of exhaust steam both for heating and really purifying water, for the ease with which they may be cleaned and for their general serviceability.

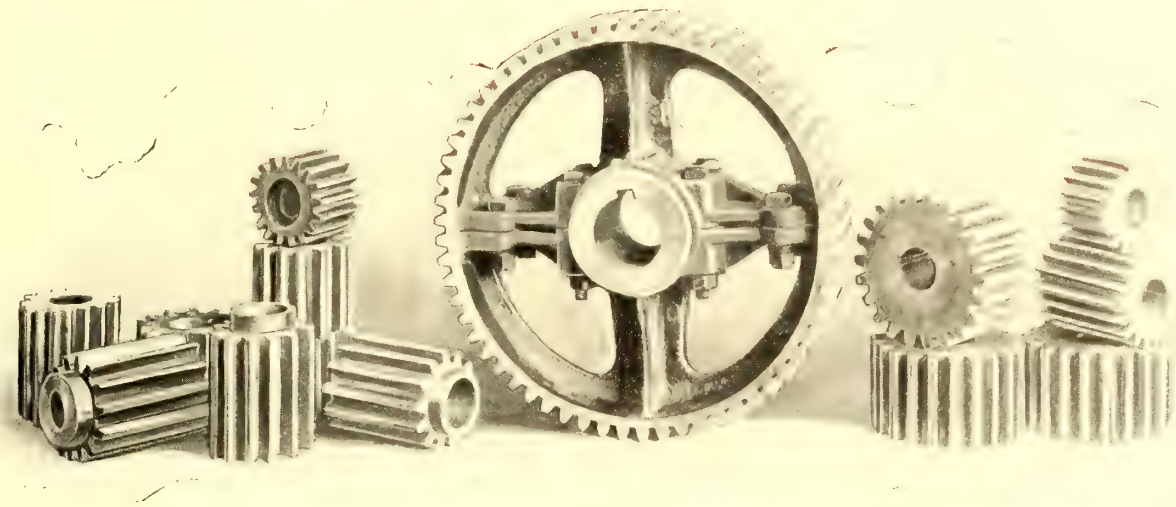
THE FALK COMPANY, Milwaukee, Wis., U. S. A.

CAST WELDED JOINTS AND CAST WELDING OUTFITS

We are the patentees of this form of Joint and have perfected it in all of its details. Our years of experience have enabled us to produce the only complete and perfect apparatus for Cast Welding Joints. We will be pleased to submit estimates for welding or quote price for complete Welding Outfits and License, thus enabling roads to do their own welding.

COMPLETE CONSTRUCTION OF ELECTRIC RAILWAYS



Our reputation in this line of work is well established. We are prepared to undertake the complete Construction or Re-construction of entire Electric Railways, Urban or Inter-Urban, including Power Plant, Roadway and Overhead, or any part thereof.

GEARS AND PINIONS

We aim to offer the GREATEST VALUE for the LEAST MONEY in GEARS and PINIONS and we claim that our gears cost LESS PER CAR MILE OF SERVICE than any others on the market. Our facilities for producing the most perfect work are constantly being added to. Prices always satisfactory.

SPECIAL WORK

We have just added a large number of the most modern and improved machines for this line of work, and our facilities for producing work of the highest quality are unsurpassed. We make FROGS, SWITCHES and CROSSINGS for electric, Cable and Steam Roads.

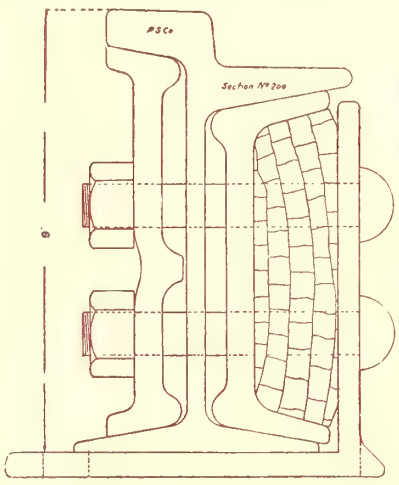
THE WEBER RAIL JOINT



IS IN USE ON EVERY TYPE OF TEE AND GIRDER RAIL.

HAS A RECORD OF MORE THAN 10 SUCCESSFUL YEARS IN THE STEAM AND STREET RAILWAY FIELDS.

COSTS ABOUT 1/3 MORE THAN THE ANGLE BAR JOINT AND ADDS MORE THAN 1/3 TO THE LIFE OF THE RAIL.

THE JOINT IS SO CONSTRUCTED AS TO INSURE AN ABSOLUTELY PERFECT FIT AT EVERY POINT OF CONTACT, THE MOST IMPORTANT FEATURE IN A JOINT.

ITS SUSTAINING STRENGTH IS GREATER THAN THE RAIL ITSELF, AND IN MANY INSTANCES IS NOW IN USE ON THE THIRD SET OF RAILS.

ALL PARTS ARE MADE FROM ROLLED STEEL AND 100% OF THE JOINTS ARE GUARANTEED AGAINST BREAKING WITHIN THE LIFE OF THE RAIL.

THIS JOINT WHEN APPLIED TO OLD SURFACE BENT RAIL ENDS WILL RESTORE TO SURFACE IN A SHORT TIME. ON APPLICATION WE WILL NAME MANY REFERENCES AS TO SUCH REDEEMED TRACK.

BALTIMORE: EQUITABLE BUILDING.

Steel Jacket Cast Weld Joints

We are now on our third season of successful welding of our **Steel Jacket Cast Weld** railjoints, and among other contracts are now completing the contract for the Milwaukee Electric Railway and Light Company of 20,000 joints, and a contract for the Columbus Street Railway Company of 5,000, and have licensed the Calumet Electric Railway Company of Chicago to weld several thousands of joints under our patents.

Our **Steel Jacket Cast Weld Joint** is pronounced a success wherever it has been introduced, and our contracts have all been doubled.

The breakage of our joint has not been 1%, and the electrical conductivity has been over 100%.

The joint made by us must in every instance be a fused joint, that is, absolutely welded. Attaching to the sides of the rail as we do, there is nothing but the actual weld to hold the joint.

We have welded joints in sizes from a 3⅜ forty-pound "T" rail to a 9-inch ninety-two pound girder rail, all with equal success.

We are the pioneers in suburban welding. In 1898 we welded eight miles between Milwaukee and South Milwaukee for the Milwaukee Electric Railway and Light Company, and this year are welding fifteen miles between Milwaukee and Wauwatosa. This was all exposed rail on suburban lines, and the one year's test has proven the efficiency of our cast welding on exposed rails, and the additional welding this year proves the practicability and success of our joint on suburban track.

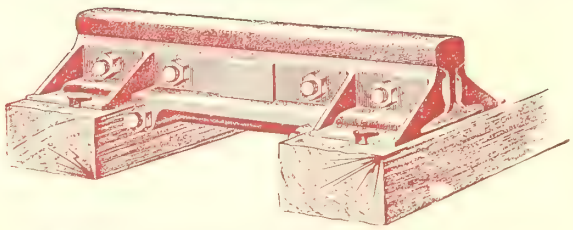
Some of the points of excellence of our steel jacket cast weld joint :

We heat the rail before welding.
We heat the jacket before welding.
We fuse our cast iron to the rail and the jacket.
This fusion makes the jacket, the rail, and the cast iron one integral body.
The fusion makes a perfectly welded joint of cast iron and steel outside and inside the welded joint.
The absolute fusion makes a perfect joint with electrical conductivity equal to that of the rail.
No ties have to be removed to weld our joint.
The firmness of the road-bed is undisturbed.
The sides of the joint are perpendicular and easy to pave against.
Our joint is as stiff as the rail itself and as durable.
It is not necessary to have any iron below the rail.
If you are interested in welding, write to us personally for prices and information,

Address: Milwaukee Railjoint and Welding Company,

MILWAUKEE, WIS.

Eastern Office: 1115 New England Building, Cleveland, O. HENRY L. PRATHER, General Agent.



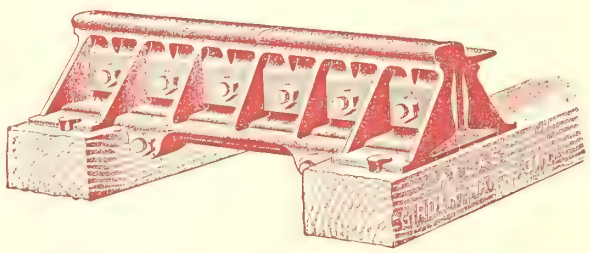
ATLAS RAIL JOINTS

We Stand with an Unbroken Record of Never a Complaint

TO AVOID DELAYS, WE ADVISE YOU TO ORDER AT ONCE

For the past two years we have been behind from four to six months on all deliveries. No charge for patents and we sell you at less price than you can buy the raw material. Every joint guaranteed as long as you run over them. You can't break them. You can't get them down. The alignment of your track is perfect. **Made of the Highest Grade of Malleable Iron.** We fit any rail or rails.

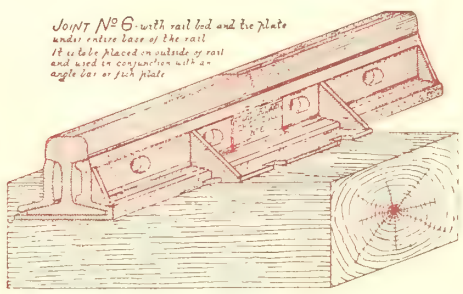
NOTICE **the large base surface on the ties! The bearings in contact with the rails! The truss under the meeting of the rail! The distribution of metal to brace against and resist the greatest strains.**



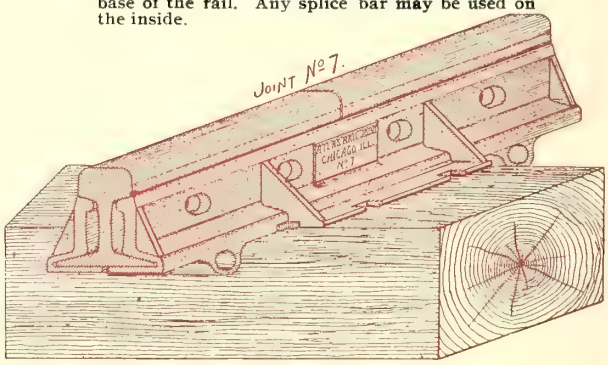
☞ Joint No. 1 is with a double truss, it is composed of two like sections, one on each side of the rail.

Joint Section No. 2.

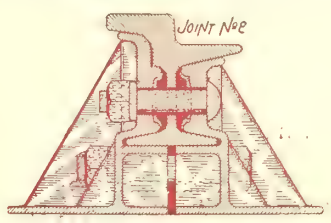
Is to be placed on outside of rail and used in conjunction with an angle bar or fish plate.



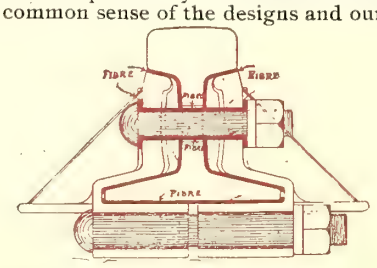
☞ Joint No. 2 with bed and tie plate under entire base of the rail. (All in one piece).



☞ Joint No. 4 is complete with double truss. It is composed of two like sections, one on each side of rail.



☞ Joint No. 5 with rail bed and tie plate under entire base of the rail. Any splice bar may be used on the inside.



Any of our Joints are adapted to be changed to a "tie" joint—note No. 6 and 7. How about your troubles with COMPROMISE joints? These joints make the track continuous; in effect securing silence, comfort and economy. **Why are these results obtained?** A look at the joints will explain why. These are stronger and cheaper than any other joints. The ease with which they are applied, as well as the common sense of the designs and our experience, enables us to **guarantee them.**

☞ Joint No. 8 shows rail raised to surface of street to avoid the use of chairs.

☞ Joint No. 9 Water Proof Insulated.

☞ No. 3 Rail brace and tie plate combined. Made to fit any rail.

☞ DATA REQUIRED IN ORDERING JOINTS

1—Full size section drawing of rail with figured dimensions.
2—Distance of bolt holes center to center.
3—Center bolt holes from bottom of rails.
4—Size of bolt holes.
5—And if the above information cannot be sent in drawings, express end of rail with bolt holes in, and state amount allowed for expansion.

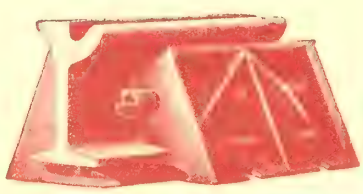
GUARD RAIL BRACE



CURVE BRACE

No Bolts or Nuts to get loose. Can apply Ten while applying One of Angle Plates.

INTERMEDIATE OR CHAIR

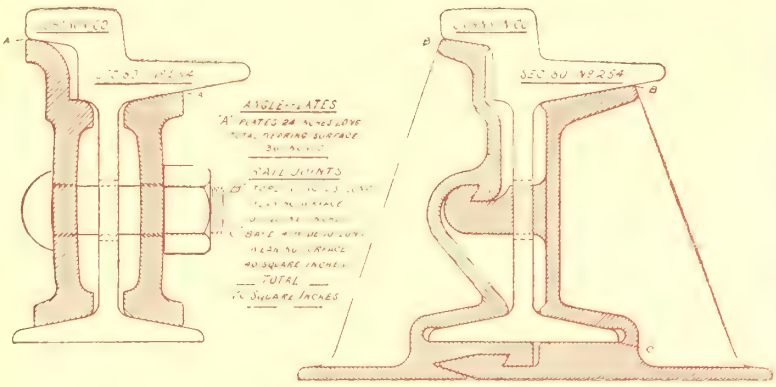
The Base of our Joints are Wider than any others.

There is no joint made that will grip the rail so tightly as it does.

It is the only joint made that has a base that is double or over the base of the rail.

There is no other joint made that supports or braces the rail at the top as we do.

It is the only joint made where a special perfectly fitted pattern is made for each section of rail.



Made of any length—and to fit any rail.

It has a much greater wearing surface to support the rail than any other joint made.

Below find comparison showing the amount of square inches of our joints as compared with the usual angle-plates.

It is the only joint made that is ground to fit the rail.

It has a much greater wearing surface to support the rail than any other joint made.

They allow for equal distribution of expansion and contraction better than any other joint made.

They are more easily and quickly applied than any other joint, and much cheaper.

Having our own Malleable Iron Works completed, we are now prepared to give all orders prompt attention

MANGANESE STEEL SPECIAL WORK

Our MANGANESE STEEL SPECIAL WORK has proven under the severest service to be *the best in America*, and after most exhaustive investigation by thorough engineers from abroad, it has been selected by them as *the best anywhere made.*

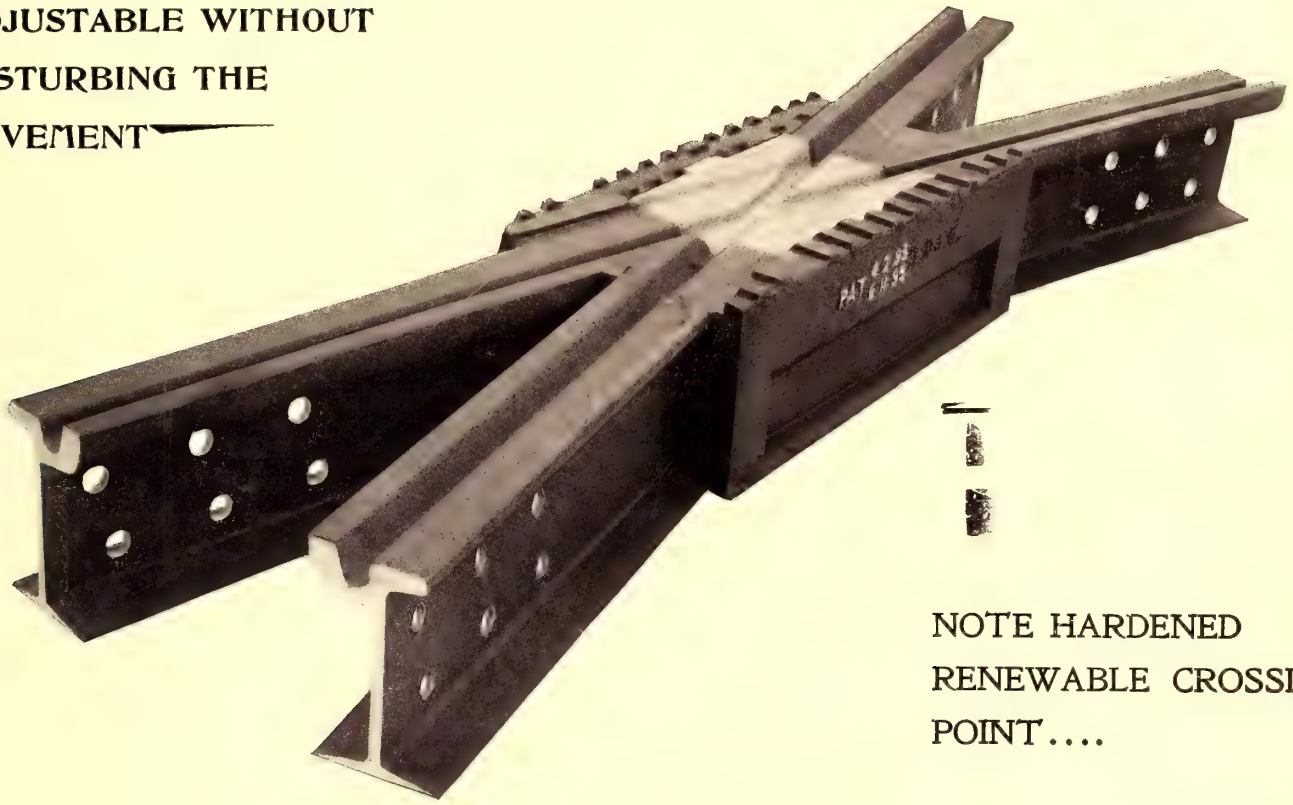
It gives the longest and most satisfactory service, and while slightly higher in first cost, is by far *the cheapest in the end.*

Theoretically, the intersecting points of special work should be made of a metal as much better than the straight track rails, as the conditions of wear at these points are more severe than they are on the straight track.

After careful investigation and experimenting we became convinced that "MANGANESE STEEL," if it did not fully come up to these theoretical requirements, did so more nearly than any other available metal. This metal, invented by Mr. Hadfield, of Sheffield, England, is unique in that it combines extreme hardness with great malleability, it being possible to bend nearly double pieces of raw "MANGANESE STEEL" castings one-half inch thick, which are at the same time so hard that they can scarcely be touched with a drill. The meaning of this is, that not only are its individual particles extremely hard, but that they adhere to each other with great tenacity, and the combination of these two qualities is the secret of the superior ability of this metal to resist wear. Hardness alone is not sufficient. We hence have adopted "MANGANESE STEEL" for use at the intersecting points of our special pieces.

We have the SOLE RIGHT IN THIS COUNTRY to use this metal in track structures.

We are equipped to Cast-Weld Joints in new or old track. This idea originated with us.



We are prepared to contract for the Building of Track and for Overhead Construction or for the entire Equipping of Roads.

We manufacture Brake Shoes and all kinds of Railway Castings.

THE ELASTIC SELF-LOCKING STEEL NUT.

The only perfect self-locking nut.
Always grips the bolt firmly.
Never works loose.
Strongest, best and cheapest Nut on the market.

These nuts are made of a flat bar of Steel, bent around into a ring and then pressed into the shape of a Nut, with an opening on the side. They are threaded slightly smaller than U. S. Standard, so that when wrenched on the bolt the split side is forced open a trifle, thereby gripping the bolt, which holds them from ever working loose like the ordinary Nut. Simple, practical, applied the same as any nut, and requires no nut-lock.

In use by largest Railroads, Machinery Builders, Engineers, etc.

THE BERLIN IRON BRIDGE CO.

Engineers, Architects and Builders of Steel Structures....

WE CAN PUT YOU UP A FIRE-PROOF BUILDING WHICH WILL NOT REQUIRE A PARTICLE OF COMBUSTIBLE MATERIAL IN ITS CONSTRUCTION—WHICH WILL NOT CONDENSE MOISTURE FROM THE UNDERSIDE—WHICH WILL BE COOLER IN SUMMER AND WARMER IN WINTER.

LISTEN TO WHAT PEOPLE SAY OF OUR CONSTRUCTION:

ABNER DOBLE COMPANY, SAN FRANCISCO, CAL.

"The power plant building which you furnished to our Company has been very satisfactory indeed, and we consider your system of construction especially suitable for power plant work."

E. F. BAKER, GENERAL SUPERINTENDENT, THE BRUSH ELECTRIC COMPANY, BALTIMORE, MD.

"I wish to state that the roof of our electric light station which your Company built for us a few years ago, and which roof was covered with the 'Patent Anti-condensation Corrugated Iron Roof Covering,' has proved itself satisfactory in every particular. The roof is well designed and strong in all its parts, we being able to hoist 20,000 pounds at any point (which has been done on several occasions). I will also state that there has been no condensation of moisture on the underside of this roof since its erection in February, 1894. I believe this kind of roof to be the only practical fire-proof construction for electric light and power stations."

C. F. HEWITT, SUPERINTENDENT, THE ELMIRA MUNICIPAL IMPROVEMENT COMPANY, ELMIRA, N. Y.

"Replying to your letter of July 20th, enquiring as to our experience with your 'Patent Anti-condensation Corrugated Iron Roof Covering' furnished us in 1892, we desire to state that we have never noticed any tendency towards condensation whatever."

L. A. PHILLIPS, SUPERINTENDENT AND SECRETARY, NEW YORK AND QUEENS LIGHT AND POWER COMPANY, FLUSHING, N. Y.

"In reference to our fire-proof roof covering that you furnished us for our power house, which was built in May, 1897, having now been up for two years, we find upon looking the matter up that there has never been one drop of water come through on our generators since the roof was installed, and we consider the covering referred to the best on the market for its purpose, and if we were to build another power house to-morrow we would use your roofing for it."

E. C. TERRY, SECRETARY, THE FARMINGTON RIVER POWER COMPANY, HARTFORD, CONN.

"Relative to 'Anti-condensation Corrugated Iron Roof Covering,' I can say that during the two years use we have found it works as represented, being entirely free from drip, and would use the same again if we were to rebuild."

CHARLES F. PRICHARD, GENERAL SUPERINTENDENT, LYNN GAS AND ELECTRIC COMPANY, LYNN, MASS.

"In 1893, we put on our boiler house at Electric Station one of your 'Patent Anti-condensation Corrugated Iron Roof Coverings.' It has served its purpose very well, we have had no trouble from condensation, and as far as we can see it is in good condition to-day."

AUG. WOLFF, CHIEF ENGINEER, THE NASSAU ELECTRIC RAILROAD COMPANY, BROOKLYN, N. Y.

"In relation to the 'Anti-condensation Corrugated Iron Roof Covering,' we beg to say that we have never had any trouble with this roof, either from sweating or leakage, and consider it a first-class piece of workmanship."

JOHN N. CANDEE, MANAGER, POUGHKEEPSIE ELECTRIC LIGHT AND POWER COMPANY, POUGHKEEPSIE, N. Y.

"Your 'Patent Anti-condensation Corrugated Iron Roof Covering' has been in use for five years; is in good condition now, and has given us excellent satisfaction."

NORMAN McD. CRAWFORD, GENERAL MANAGER, HARTFORD, STREET RAILWAY COMPANY, HARTFORD, CONN.

"We have used your 'Patent Anti-condensation Corrugated Iron Roof Covering' for some time past and have found it entirely satisfactory. The application of asbestos paper to the lower or inner side of the roof entirely prevents the formation of condensation and is particularly desirable for use in power stations where the difference in temperature ordinarily causes dripping from the roof during the winter months."

L. BENTLEY, SUPERINTENDENT, THE NEW LONDON STREET RAILWAY COMPANY, NEW LONDON, CONN.

"I take pleasure in stating that your 'Patent Anti-condensation Corrugated Iron Roof Covering' which has been in use on our power house for the last three years, has given entire satisfaction, and I can heartily recommend it to anyone contemplating the building of a power station. I fail to see how it could be improved, as it has answered every requirement, and has needed no attention as yet."

C. E. DOOLITTLE, MANAGER, THE ROARING FORK ELECTRIC LIGHT AND POWER COMPANY, ASPEN, COL.

"We take pleasure in stating that we are very much pleased with the iron roof and 'Patent Anti-condensation Corrugated Iron Roof Covering' which you furnished for our electric power station in the fall of 1892. The roof has never dripped, condensed moisture from the underside, or caused any trouble of any kind whatever."

ROBERT McCULLOCK, VICE-PRESIDENT AND GENERAL MANAGER, CITIZENS' RAILWAY COMPANY, ST. LOUIS, MO.

"In reply to your inquiries as to our satisfaction with a car-house roof which you erected for us in 1894, I will say that it is in perfect condition to-day; it is water-proof as well as fire-proof, there is no dripping from condensed moisture, its architectural appearance is pleasing, and if I was ordering another roof, I would say, duplicate this, as I could suggest no desirable change."

B. B. NOSTRAND, JR., TREASURER AND MANAGER, THE SING SING ELECTRIC LIGHTING COMPANY, SING SING, N. Y.

"The 'Anti-condensation Covering' with which you lined the corrugated iron roof furnished us in 1894, has fulfilled the guarantee made for it, and we have not been troubled from condensation of moisture and are well pleased with it."

R. CRAWFORD, SUPERINTENDENT, THE STAMFORD GAS AND ELECTRIC COMPANY, STAMFORD, CONN.

"We have found your 'Anti-condensation Corrugated Iron Roof Covering' to be all that you claimed, and recommend its use in electric stations or buildings which must be free from the drip caused by condensation."

JOHN H. KELMAN, GENERAL SUPERINTENDENT, STANLEY ELECTRIC MANUFACTURING COMPANY, PITTSFIELD, MASS.

"Relative to the 'Anti-condensation Corrugated Iron Roof Covering' which you applied to the iron building you constructed for us in 1893, we have had no trouble whatever from condensation on the interior surface of this roof. The asbestos lining accomplishes the desired results. We have used this building as an insulating department in which it is very necessary that no condensation on the roof should occur."

W. O. HALLOWELL, SUPERINTENDENT TORRINGTON AND WINCHESTER STREET RAILWAY COMPANY, BURRVILLE, CONN.

"Will say that we have had your 'Patent Anti-condensation Corrugated Iron Roof Covering' in use on our power plant for over two years, and it does not drip or condense moisture from the underside. I consider it a first-class fire-proof roof covering."

H. W. YORK, CHIEF ENGINEER, THE UNITED ELECTRIC LIGHT AND POWER COMPANY, NEW YORK, N. Y.

"The 'Anti-condensation Roofs' which you placed on our 28th and 29th Street stations about four years ago have given entire satisfaction in every way, and we have never been annoyed by any dripping from the underside, although the largest roof is over the engine-room of our 28th Street station where the air is always moist and warm."

CHARLES A. RICHARDSON, PRESIDENT, THE WORCESTER CONSTRUCTION COMPANY, WORCESTER, MASS.

'We have used your 'Anti-condensation Corrugated Iron Roof Covering' on our building on the Gloucester, Essex and Beverly Road, and also on the Warren, Brookfield and Spencer Road, and the same has given entire satisfaction."

MICHIGAN MFG. CO., YPSILANTI, MICH.

Some Important Reasons Why Our

AUTOMATIC SIGNAL for ELECTRIC RAILWAYS

Is Superior to any other Signal in use

Works automatically. Enclosed in iron box.
Operates from the trolley.
Impossible for trolley to catch in the overhead switch.
No part of signal can be affected by atmospheric conditions.
So perfectly insulated that it will not burn out.
Does not require a drop of oil.
Should the power be lost for a time, signal will re-light when power is restored.
Works equally well regardless speed of car.
There are two lights at each end of block—an orange and a green one—so arranged that when a car enters turnout, one lights at each end simultaneously, thus enabling the motorman to know whether the signal is working, and whether he is following a car, or one is coming from the opposite direction.
No lamps are required for resistance, as in other signals.

This signal has been thoroughly tested on the Quincy, Mass. road and Newton & Boston road.

Full particulars on application.

The Comparative Effect

of these two

Streaks of Lightning . .

Pole Arrester with Iron Cover

will depend on whether the lines which they strike are equipped with efficient lightning arresters.

GARTON Lightning Arresters..

have the smallest air gap, lowest resistance discharge circuit, do not ground your circuits, and are low in price.

They furnish ...

ABSOLUTE... PROTECTION

A large number of Pole Arresters is becoming the prevalent practice. They offer many paths of escape for the discharge before coming to your station, where your largest investment is; relieve the strain on your Cars, and on the insulation of your entire circuit, and overcome the difficulty occasioned by nodal points.

Double the number you ought to have won't cost as much as the repairs, loss of service, dissatisfaction of customers, etc., following one burn-out.

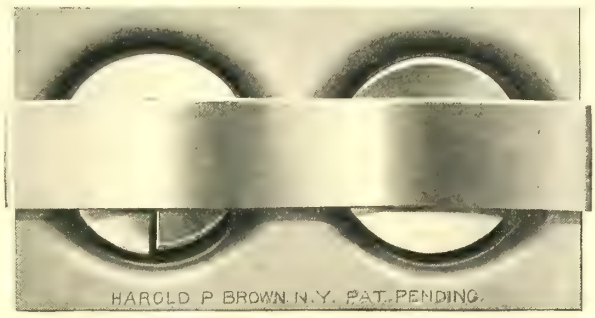
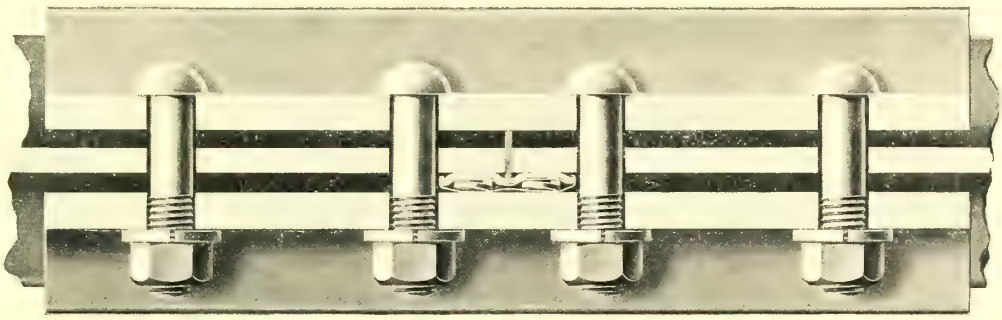
ONE OF THESE BONDS IS SHOWN BELOW FULL SIZE.

THESE flexible bonds were used one year on ballasted road with heavy rail, and are now being replaced with Plastic Bonds.



The joints were well maintained, and the rail ends show no wear. We have had complaints from Plastic Bonds after some three years use on track with loose joints, though never a case like this.

But we have predicted this, and on the next page you will see how we meet this trouble.



THE SOLID COPPER BOND

FRONT

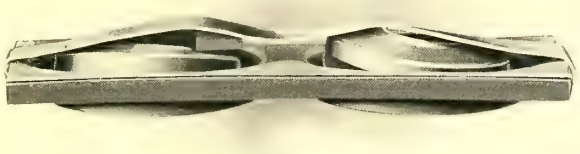
BOTTOM

SECTION

THE above full size cuts show the No. 00,000 bond for rails with 9-32 inch bonding space. It is made of a rectangular piece of rolled electric copper 3 inches long, 1¾ inches high and ⅛ of an inch thick.

A cup-shaped projection is pressed near each end so as to give a contact against rail web close to the end of rail.

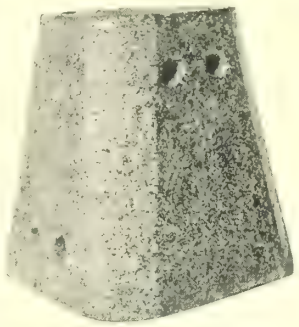
Inside the cups is a piece of sheet steel supporting a pair of special steel springs; the sheet is used to keep springs from wearing into copper. These pieces are held together by a small sheet-iron strap.



The entire bond is amalgamated to prevent rusting and the contact surfaces are covered with Plastic Alloy. The springs are proportioned to give a pressure of 1,000 lbs. per square inch when angle plate is bolted up. The bond does not interfere with the mechanical fit of angle plate, and the sharp web on top of spring cuts through the soft iron strap and into angle plate, thus aiding conductivity of the bond.

To apply this bond it is only necessary to brighten rail web beyond end bolt hole with the usual hand-power grinder and emery wheel.

The surfaces are then amalgamated and covered with a thin layer of Plastic Alloy. When rail ends move under passing cars, the bond is held against the rails by the springs, and the motion maintains the electrical contact.



The depth of the springs is varied to suit the clearance between rail and angle plate, and the size of the copper will be altered to suit.

This bond is the cheapest and most efficient copper bond on the market, and its performance is guaranteed when used in accordance with directions.

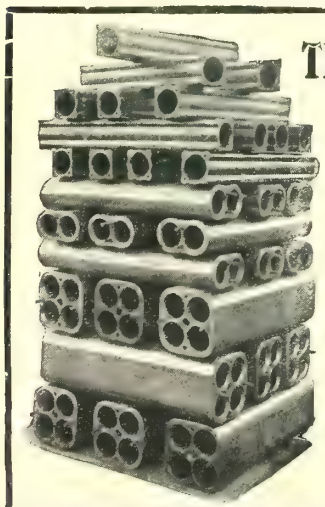
For Underground Telephone, Telegraph and Electric Light Wires and Underground Trolley System for Electric Street Railways.



MANUFACTURED BY **THE H. B. CAMP CO., Aultman, O.**

Our conduit is made of specially prepared clays, is thoroughly vitreous and glazed, making it acid, gas and water proof, and is not affected by electrolysis. Standard size is 3 inch internal diameter. However, we can make any size or multiple duct. Our patent mandrel used in laying our conduits prevents the possibility of shoulders, and insures good alignment of bore. We claim for strength, economy, durability, cheapness and perfect insulation it is the best, and is used by the most prominent companies. Any information promptly given.

Write for catalogue.

THE H. B. CAMP COMPANY,

AULTMAN, OHIO, U. S A.

THE MASON VITRIFIED SALT GLAZED TERRA COTTA CONDUITS

FOR UNDERGROUND ELECTRIC WIRES.

FIVE POINTS OF EXCELLENCE.

1st. Being of *Vitrified* Terra Cotta they do not absorb water and when properly laid are indestructible by the elements.

2d. Being Salt Glazed *inside* as well as out they offer little or no resistance by friction in drawing the cables.

3d. Our *standard length of 30 inches* is the most suitable to insure perfect vitrifaction and glazing, is most easily handled, least liable to breakage in handling, and consequently the most economical.

4th. Being connected by dowels, perfect registration and alignment are secured without the aid of skilled labor, and once laid the joints are not displaced by ramming concrete or otherwise.

5th. As no mortar or other substance is allowed to enter the ducts while being laid there is no cleaning of them required preliminary to drawing the cables.

THE ...PAINT WONDER...

PYRO PAINTS (Patented Dec. 1, 1891), after fourteen years of tests, have proven their absolute indestructibility by the action of the elements.

Five times the durability of any other paint, is guaranteed on Cars, Trucks, Bridges, Poles (iron or wood), Roofing, and all Surfaces, whether cold or heated.

The only paints that will stay on galvanized iron.

The only perfect insulator for electric wires. Coiling does not break or crack the coat. The only paints that are proof against rust under all conditions.

The only paints worthy of the name "FIRE PROOF."

"The Shearer-Peters Paint is the best we have ever used. We have adopted it as our standard for locomotive front ends, etc."—W. H. Lewis, Superintendent Motive Power, N. & W. Railroad.

"We have never yet found any paint excepting the Shearer-Peters Pyro that would stand the combination of heat and steam such as our works are subjected to."—Wm. N. Morgan, Superintendent Crozer Iron Co.

"Roofing covered with Shearer's Patent Pyro Paint, in Winfield, Kan., fourteen years ago, is still all right—both metal and wood. The best paint on earth."—B. F. Wood, for seven years a member of School Board. [Mr. Wood refers to any bank in Winfield.]

Send for our booklet, which tells what Pyro Paints have done for others. Actual time tests are what count.

FOR ALPHABETICAL INDEX TO ADVERTISERS, SEE PAGES 23-25

STATIONARY AND PORTABLE
...Air Compressors...

You will find these compressors useful for a variety of purposes, more numerous than we can briefly state, but the principal ones are as follows:

They furnish compressed air for blowing out dust from motors mounted on car trucks, for blowing out dust from generators in the power house, for blowing dust out of car cushions, for sand blasting and cleaning rusty iron, for white-washing and painting car barns by means of compressed air, for operating air lifts and hoists, for lifting car bodies or trucks, for air jacks arranged either on a truck to wheel about or arranged on a track in the pit. We manufacture both air hoists and air jacks in all varieties. You will also find the portable air compressor useful in drilling holes for bonding your rails. By connecting a fish pole with the trolley wire and making a ground connection with the wire and coupling your air drill to the tank on the truck, you can then drill the holes for the bonds much quicker than in any other way. You can also use this compressor to advantage in connection with the oiling system of your engines and generators by elevating the oil up to the level of the filters. For chipping and riveting hammers, and in special work where air drills are very convenient and much quicker than ratchets.

The portable air compressing apparatus, up to and including size D-4 compressor, is of suitable weight so that the truck can be hauled around by hand and can therefore be used in car barns and shops where air hoists and compressed air tools are installed, thereby avoiding the necessity of an expensive system of air piping.

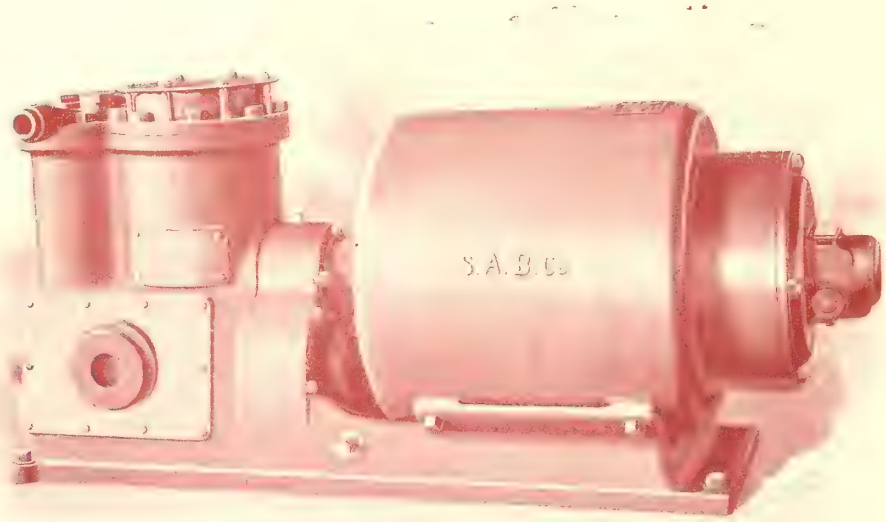
Standard Air Brakes



("THE PIONEERS")

FOR RAPID TRANSIT RAILWAYS

Our Geared Axle Driven Compressor Type of Air Brake is equally adapted for high speed interurban cars or for cars in ordinary city service. It is an absolutely reliable and efficient Air Brake, the result of several years experimenting and was perfected by us early in 1898. It is of moderate cost, inexpensive to maintain, compressor works only as needs require, and maintains, automatically, maximum air pressure for every stop. It has numerous points of merit possessed by no other air brake manufactured.

GEARED AXLE DRIVEN COMPRESSOR

Our Motor Driven Compound Compressor Type is particularly adapted for elevated trains or any heavy electric service. Slow speed and low gear ratio, together with uniform load on cranks and entire absence of shocks on passing centres, insure quiet running and long life.

Being compounded is of much higher efficiency than single stage compressors.

Is dust and rain proof, self oiling and is designed and built to last for years. The results with this type have been so satisfactory that we have made it our standard for heavy service.

"Pioneer," One who goes before to remove obstacles and prepare the way for others.
STANDARD DICTIONARY.

THIS COMPANY is the recognized Pioneer in the development of the Air Brake and its practical application to rapid transit service.

As pioneers we have removed the numerous obstacles, and have not only prepared the way, but are running our works to their fullest capacity to keep up with orders.

We early recognized that there were such a large variety of conditions to meet that no one type of Air Brake could practically fulfill them all.

To properly meet these requirements we have perfected the various systems of Air Brakes and are prepared to furnish the proper type of brake best adapted to any class of rapid transit service.

We build both automatic and direct systems, with air supplied by either independent motor driven compressor, axle compressor, or by storage reservoir. We will also furnish the vacuum system when conditions warrant its use. Each system has its advantages.

Our new catalogue describes and illustrates these various types and systems so fully as to enable the railway manager to determine what particular type of our Air Brakes is best suited to meet his particular requirements.

Perhaps our experience may also be of some benefit to you, as it extends over a period of 10 years in Street Railway Brakes, and considerable longer time with steam railway service.

The Storage Air Brake

WON'T STOP

THE EARTH, BUT WHEN APPLIED TO

A CAR

PROMPT AND RELIABLE BRAKING IS INSURED

"IN A JIFFY"

Twelve cars like the above on the Detroit & Pontiac Railway equipped with the Storage System. In operation one year. *Not one dollar for repairs.* Never failed to act instantaneously.
Contract awarded for the Storage System solely on its distinctive merits, against four competitors.

ORDERS RECEIVED SINCE MAY 1st, '99...

Kansas City and Leavenworth Ry. Co.,	10	Brake Equipments
Cleveland & Eastern Ry. Co.,	8	" "
Detroit, Rochester, Romeo & Lake Orion Ry. Co.,	6	" "
Mahoning Valley Ry. Co.,	3	" "
Detroit & North Western Ry. Co.,	12	" "
Sandusky and Interurban Elec. Ry. Co.,	3	" "

Why We Got Their Orders and Out-distanced our Competitors

Simplicity, No Complications of air pump, motor, controller, etc. All eliminated. Absolutely Noiseless, No Repairs required, Never Out of Order.

...Perfect Braking is only obtained by using the Storage System...

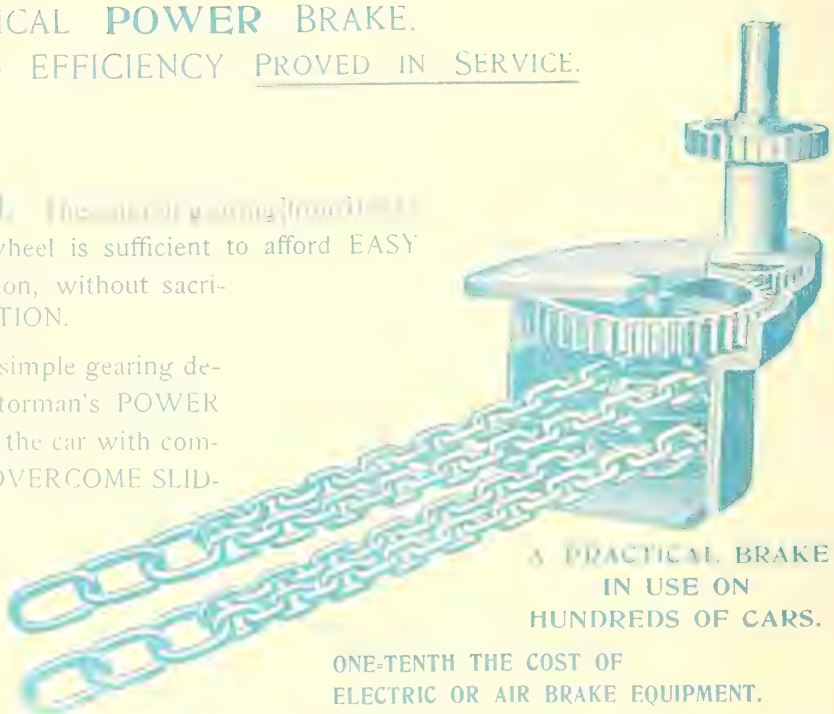
EQUIP YOUR CARS WITH

Sterling Safety Brakes



A MECHANICAL **POWER** BRAKE.

RELIABILITY AND EFFICIENCY PROVED IN SERVICE.

ADVANTAGES:

EASE OF OPERATION. The [illegible] post to double sprocket wheel is sufficient to afford EASY and POSITIVE manipulation, without sacrificing QUICKNESS of ACTION.

GREAT POWER. The simple gearing device MULTIPLIES the motorman's POWER and enables him to control the car with comparative ease, and greatly OVERCOME SLIDING of WHEELS, thus [illegible] positive stop in any [illegible]

A PRACTICAL BRAKE IN USE ON HUNDREDS OF CARS.

ONE-TENTH THE COST OF ELECTRIC OR AIR BRAKE EQUIPMENT.

SAFETY. Due to multiplied power and double chain connection. Should one chain break the other BECOMES OPERATIVE INSTANTLY.

ECONOMY. The wear on chain is reduced to the minimum, being EQUALLY DISTRIBUTED, thus avoiding the continual "grinding," wearing through and replacing of chain, common to the ordinary brake.

STERLING INSULATING

THE NEW MEAKER REGISTER

Is a Radical Departure in Construction, as it is in General Scheme of Operation.

This Register, combining all the essential features of the ordinary type of Register, possesses the added advantage of having a totalizer composed partly of letters and partly of figures, the figures only being used in the ordinary taking of statements (read the same as a 10,000 totalizer). The complete reading can be taken by those only who are allowed by the management to know the value of the several letters.

The Objects Accomplished are these:

An additional check is placed on the conductor, who is unable to read the grand total.

Your competitors or other interested persons are unable to keep a record of your business.

The manager is able to easily check the bookkeeping of the office.

Registers totalizing to 100,000 all in figures (that is, without the letter symbol) are furnished if desired.

The mechanism so completely interlocked that, even with the case off, the figures cannot be moved, either in totalizer or trip number, except in the regular way.

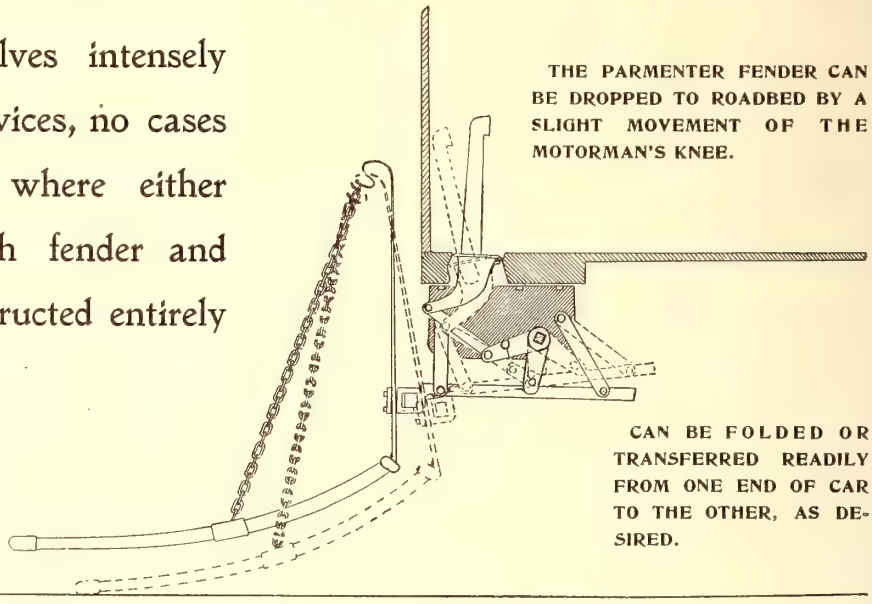
They cannot be manipulated in any way. As they can only be assembled with figure nines at the window position, it is impossible to take them apart and then put them together at a lower number.

They are practically without springs, only three being used. All motions are positive, absolute and beyond question.

OUR PORTABLE REGISTER.

Complete Descriptive Catalogue, showing construction in detail, mailed on request.

OUR REGISTERS ARE IN USE IN ALL THE PRINCIPAL CITIES.



REFERENCES ON APPLICATION.

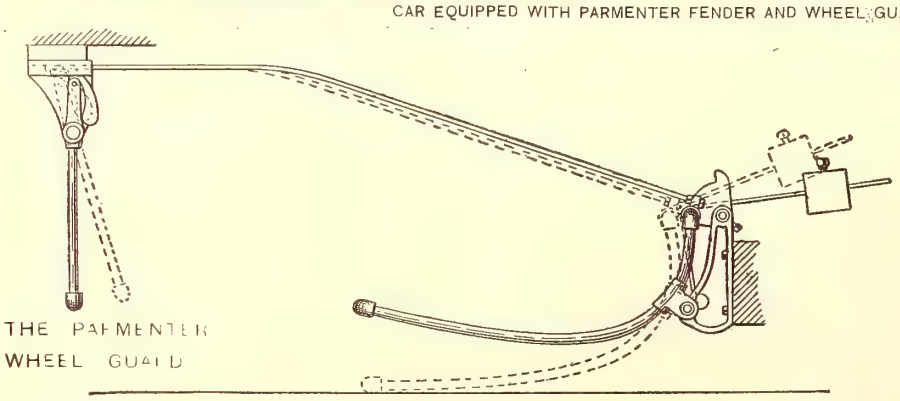
PARMENTER FENDERS AND WHEEL GUARDS

Have proved themselves intensely practical life-saving devices, no cases having been reported where either one has failed. Both fender and wheel guard are constructed entirely of metal, easy to adjust and easily maintained.



THE PARMENTER FENDER CAN BE DROPPED TO ROADBED BY A SLIGHT MOVEMENT OF THE MOTORMAN'S KNEE.

CAN BE FOLDED OR TRANSFERRED READILY FROM ONE END OF CAR TO THE OTHER, AS DESIRED.

CAR EQUIPPED WITH PARMENTER FENDER AND WHEEL GUARDS

THE PARMENTER WHEEL GUARD

The wheel guards can be used in connection with fenders or independently.

THE FULLEST INVESTIGATION IS EARNESTLY SOLICITED.

DAMAGE TO HARPS

and overhead construction due to the trolley leaving the wire, often causes great expense for repairs and ties up the line.

It can be prevented absolutely by using the **Wilson Trolley Pole Catcher** which costs but eight dollars per car.

It is easily attached to the car, is small and never in the way, and will hold the pole surely and safely whenever it leaves the wire.

The hand of the conductor will be more free to jerk the rope leading to the cash register if he doesn't have to spend so much time pulling at the trolley rope.

The Wilson Trolley Pole Catcher means more money to every street car line. It lessens the expense for repairs on the overhead construction. It lessens the distraction of the conductor's mind from the collection of his fares and consequently he runs less chance of missing them.

Our book entitled "**A Big Leak Stopped,**" tells all about it. Send for one. It is free.

THE

Hipwood-Barrett Fender

THE accompanying cuts were made from a series of 1200 Mutoscopic pictures taken at the rate of 40 per second by the American Mutoscope Company for use on the Biograph and in the Mutoscope to show the practical working of the only efficient street car fender. The pictures show the car running at the rate of 15 miles per hour, over an uneven road-bed, and performing its life-saving work under conditions which actually exist. The rapidity with which this fender is operated can be judged by the fact that the car covered a distance of two blocks, the fender was dropped, dummies picked up and carried some 50 feet, then removed, and the fender disposed of under car, all within 25 seconds.

Repeated tests have proved this fender to be in every way efficient, and its PERFECT ADAPTABILITY TO UNEVEN SURFACES, UNIMPAIRMENT OF EFFICIENCY BY OSCILLATION OF CAR, INSTANTANEOUS OPERATION BY MOTORMAN, NON-INTERFERENCE WITH USE OF CAR AND EQUIPMENTS, AND ACTION UNAFFECTED BY ICE OR SNOW, make it the only practical fender suitable for street railways. These features, together with its ready disposal under the car in 3 seconds, when not in use, commend it at once to practical street railway men.

The unique shape of this fender, particularly when painted to match the dasher, tends to add to, rather than detract from, the symmetrical lines of the car.

14 Points of Advantage Possessed by the Providence Fender.

FIRST. The device is such that it **will remove the endangered person from the track** if the motorman should fail to stop the car in time.

SECOND. This removal is effected by a **projecting cradle** on which the person may fall, and which at the time of using touches the ground.

THIRD. It being impracticable to carry such a cradle touching the ground all the time, **it is possible for the motorman instantly to drop it,** while at the same time his hands are free for other purposes.

FOURTH. The mechanism is such that the motorman, after dropping his fender, **can again raise it without stopping his car** or leaving the front platform.

FIFTH. The front edge of the cradle is furnished with such rolls, and the cradle itself is of such form, that it **may be dropped on any ordinary road surface without risk of breaking.**

SIXTH. **The front edge of the cradle is yielding,** so as to cushion the blow against the foot or body, if the person has fallen.

SEVENTH. The front end of the car is furnished with **a resilient shield,** covering all the rigid projecting parts of the car, such as the bumper, the draw bar, and the fixtures by which the fender itself is attached to the car.

EIGHTH. The fender is strong enough and elastic enough to serve as **a substantial buffer** in colliding with other vehicles, so as, within a considerable limit, to receive all the damage itself, and prevent injury to both colliding vehicles.

NINTH. It is **detachable from the car,** so that in case of accident the conductor and motorman may readily remove it without the use of tools.

TENTH. It is **foldable against the dash,** so that if fenders are attached to both ends of the car, the rear fender, and in the car house both fenders, may be turned up.

ELEVENTH. It has a breaking part **inexpensive to repair.**

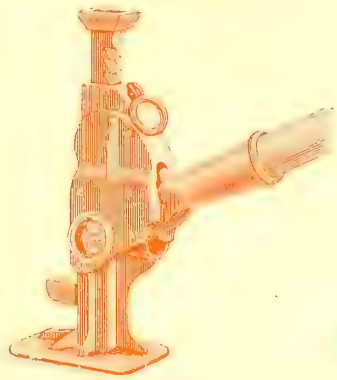
TWELFTH. It is **easily transferable** from one end of the car to the other, so that, if necessary, it may be quickly so transferred by the conductor and motorman at the end of each trip.

THIRTEENTH. It is **of simple construction and easy to repair,** and to that end all the parts are interchangeable.

FOURTEENTH. All fenders for cars of the same company are **interchangeable.**

IT is not enough to say that a fender "is constructed entirely of metal." A cheap fender, constructed of gas pipe and hoop iron, could be thus described, and so deceive the reader and purchaser.

***The Providence Fender** is not only "constructed entirely of metal," but is made of the **best quality of spring steel,** and the attachments are made of the **best malleable iron.** There is no gas pipe, hoop iron, rope netting, or **other cheap material** used in its construction.*



*No expense is spared either in material or labor, to make the **Providence Fender** the **best life saving device** ever attached to an electric or cable car. In fact, it is the only car fender made that, when properly used, saves 100 per cent. of all lives placed in jeopardy.*

The following Table of Speed Run by Electric and Cable Cars may be of Interest to Railroad Men:

1 mile per hour	88 ft. per minute	1.466 ft. per second
2 " "	176 " "	2.933 " "
3 " "	264 " "	4.4 " "
4 " "	352 " "	5.866 " "
5 " "	440 " "	7.333 " "
6 " "	528 " "	8.8 " "

LIGHT

AUTOMATIC LOWERING JACK No. 2

TRIP JACK No. 12

BARRETT

Lifting Jacks

.. FOR ..

ELECTRIC AND CABLE CARS

The only Jacks with an automatic lowering device, by which any load can be gradually lowered by the same movement of the lever as in raising.

By carrying a "Barrett" Jack in at least every other street car, the Jack would be instantly at hand in case of derailment and the line would not be blocked and passengers inconvenienced. Just one experience of this kind would more than pay the cost of Jack in the fares saved. One car off the track stops all others. The "Barrett" Jack reduces such risks to a minimum and in a year's traffic will save thousands of dollars.

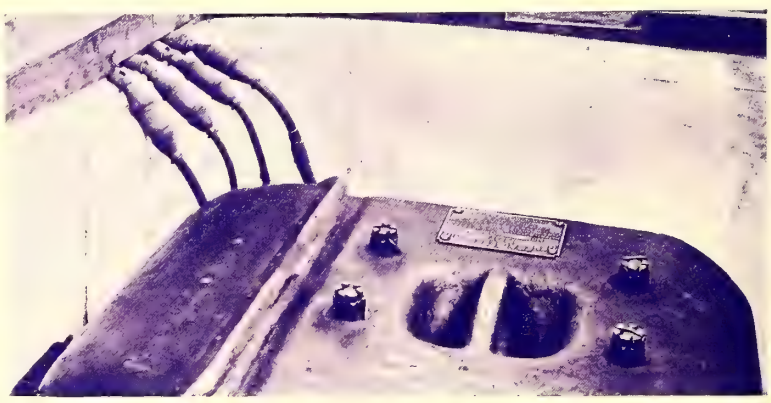
STREET RAILWAY SUPPLIES

To Meet All Requirements



SAMPLE FREE.....

HERE is a **NEW INSULATING CONNECTOR** which is a permanent, adjustable device for doing away with the old fashioned method of taping the connections between motor and cable leads. Time is valuable! All railway men know perfectly well that the old method of taping the two-way connectors of the motor leads, is a time waster. This device will save you time and money.

It is water-proof, absolutely indestructible and costs but little. A sample and full particulars are yours for the asking.

Try it and be convinced.

THIS SHOWS INSULATING CONNECTOR IN USE

WE ARE HEADQUARTERS FOR ...

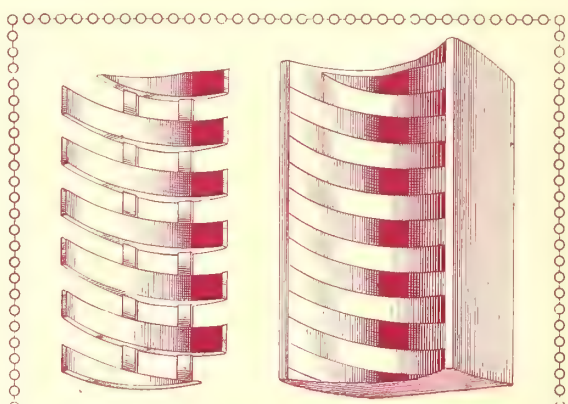
SPIRAL MOTOR AND ... TRUCK ... BEARINGS



The **SPIRAL MOTOR BEARING** consists of an iron shell, lined with two dissimilar metals, viz: a skeleton bronze lining, cast in the form of a "reversed spiral," held in place by anti-friction metal, which also forms part of the bearing surface. The anti-friction metal lessens any liability to heat; the bronze acts as a check on the wear of the softer metal. The combined wear of the bronze and babbitt gives the remarkable showing which the Spiral Bearing is making. The oil grooves, cast in the bronze lining, carry the oil from the dope hole to the ends of the bearing and back again, thus insuring perfect lubrication and preventing any waste of oil. The saving in lubricants is an important feature of the Spiral Bearing.

Skeleton Bronze Lining — Finished Bearing Shown in Half Sections

The **SPIRAL TRUCK BEARING** consists of an iron shell, in which a skeleton bronze lining, in a "spiral" form, is held in place by anti-friction metal. To assist in meeting the decrease in bearing surface when a new bearing is placed on a much worn journal, the anti-friction metal is poured so as to form a coating over the whole surface of the bearing, about one-sixteenth of an inch thick.

Spiral Bearings do not cut the journals but insure an even and minimum wear.

Skeleton Bronze Lining — Finished Bearing

A special feature of the Spiral Bearings is their absolute safety. In the event of the heating of an armature bearing, from any cause, **the bronze lining prevents the letting down of the armature.**

HIGHEST DEVELOPMENT OF

ELECTRIC HEATERS

FOR STREET RAILWAY CARS

Only perfect and successful Heater on the market. Not one authenticated failure in seven years. Over 100,000 heating coils in service. All other Heaters experimental.

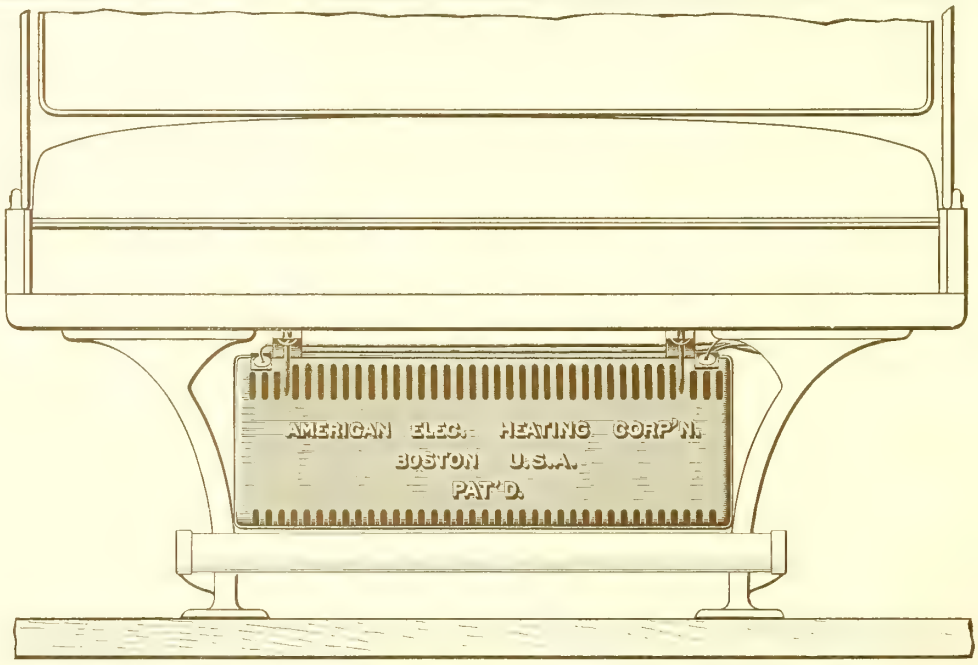
The Consolidated Car Heater has already been applied to over 8,000 Street Railway Cars in this country. Standard on all the largest surface railroads in all the large cities. Adopted by the Metropolitan Street Railway of New York City, after competitive tests.

Perfect Heat Regulation; from one to five intensities and more, by means of Regulating Switches.

CONSOLIDATED CAR HEATING CO.

513 Western Union Bldg., CHICAGO, ILL. Albany, N. Y. 716 Chemical Building, ST. LOUIS, MO.

THE PINTSCH GAS LIGHTING SYSTEM



Has been adopted as the **STANDARD LIGHT** by the Broadway and Third Avenue Cable Lines of New York; the North and West Chicago Cable Lines; the Columbus Central Electric Line of Columbus, O., and Denver City Cable Co.; also by one hundred and three of the most prominent railways and by the Pullman and Wagner Palace Car Companies in the United States.

It has been the standard lighting system in Europe for many years, and is applied to 85,000 cars, 3,100 locomotives and 800 buoys in Europe, the United States, South America, India and Australia. For particulars address

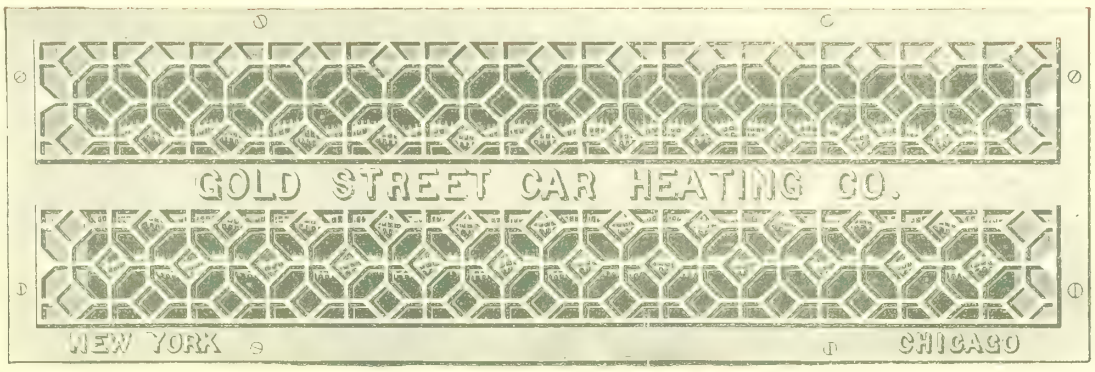
Manufactured by ...
THE SIMPLEX ELECTRICAL COMPANY
Cambridgeport, Mass., U. S. A.

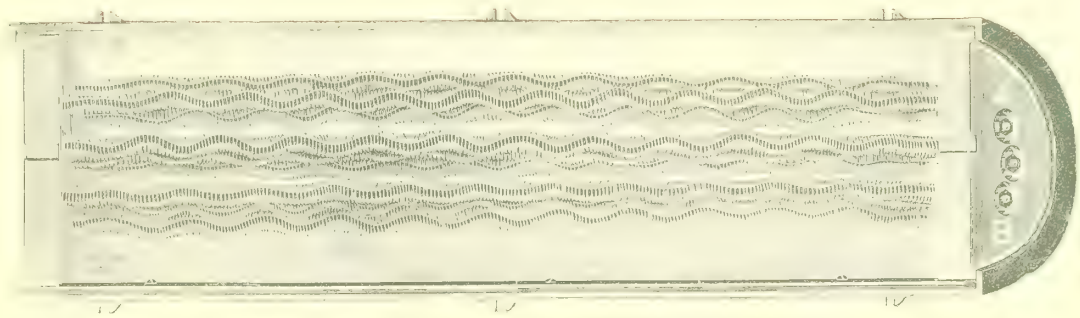


Gold Street Car Heating Company

658 Rookery, CHICAGO, ILL. Frankfort and Cliff Sts., NEW YORK.

The "**GOLD IMPROVED ELECTRIC HEATERS**" have invariably shown the highest efficiency in delivering the warmed air into the space to be heated.

The very even graduation of the temperature, and the uniform distribution of the heat at all times are especially **superior features of the Gold Electric Heaters.**



The economical consumption of current, the low cost of original installation, and the simple method of applying our electric heaters, are also prominent points of advantage, and are unequalled in any other electric heater on the market.

Gold's Improved (3 Degree) Panel Electric Heater

The Gold Electric Heaters

always maintain their original condition in every particular. There is no possibility whatever of the wire corroding, burning out, or short circuiting, and above all else they do not increase in consumption of current with usage (a very detrimental feature and one that shortens the life of some other types of electric heaters).

Interior View of Gold's Improved (3-Degree) Panel Electric Heater.

We Challenge Comparison

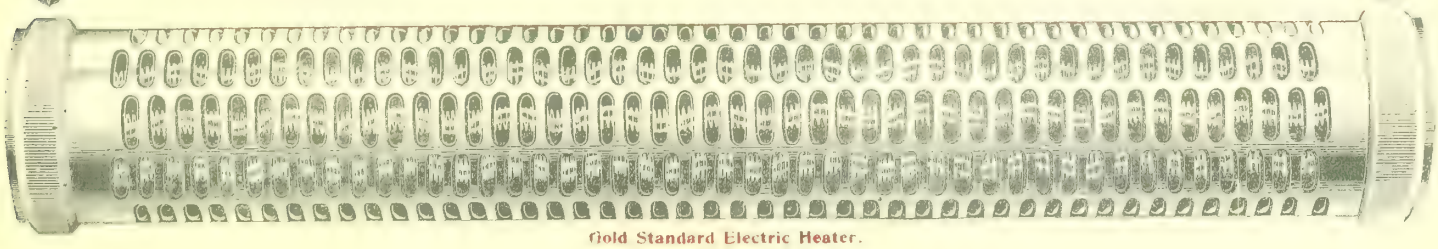
of our Improved Electric Heater with any other on the market, in the following very essential features:

Efficiency

in every particular, with regard to the amount of heated air delivered into the car body, and the even and thoroughly uniform manner of its distribution.

Economy

in consumption of current, in first cost of the heaters, cost of application, and in cost of maintenance.



Simplicity

in construction of the heaters, arrangement for connecting to the regulating switch, and installation.

Durability

There has not been one of our heaters sold which has not given entire satisfaction. We are prepared to furnish prospective buyers with a list showing where every heater we have ever made is in use to-day and giving results superior to what we promised.

Catalogues, circulars, and further information cheerfully furnished.

Gold Standard Electric Heater.

BAKER HOT WATER HEATERS FOR ELECTRIC CARS

Type of Baker Heater used in large Electric Car

Positively Non-Freezing.

Cheaper, More Constant, Satisfactory and Agreeable than Electricity.

Various Sizes.

Simple but Perfect in Operation.

Hot Water pipes run around the car and at the feet of every passenger. The Heater proper may project half-way, or be placed entirely within the vestibule, and thus keep the motorman warm, and his windows free from frost.

In use on the Detroit, Ypsilanti and Mt Clemens Railway Co., Ann Arbor, Mich.; Detroit, Lake Shore and Mt. Clemens Railway Co., Detroit, Mich.; Twin City Rapid Transit Co., Minneapolis, Minn.; Milwaukee Electric Railway and Light Co., Milwaukee, Wis.; Waterloo and Cedar Falls Rapid Transit Co., and others.

COMBINATION SNOW PLOW AND SWEEPER

(Patented)

OVER 300 IN USE...

ADOPTED BY THE LARGEST STREET RAILWAYS IN THIS COUNTRY

THE ONLY TRACK SWEEPER THAT

CLEANS THE TRACK IN ONE OPERATION

Absolutely Impossible to Stall it, no matter how Deep or Heavy the Snow.

Our Combination Snow Plow and Sweeper for Electric Street Railways combines the utility of a rotary snow plow for removing heavy accumulations of snow from the tracks, and of a sweeper for cleaning the rails *entirely* of snow, leaving them *swept clean*, giving full traction for the wheels to propel the cars, even after passing through snow-drifts five or six feet high. This is the record made by these machines in the very heavy snows of last winter. *They kept the roads open and the cars running on schedule time where all other means failed.*

They have demonstrated their Efficiency during the last five winters, and we have never had one failure.

In use on the following Roads, to which we respectfully refer

Chicago Electric Traction Co., Chicago.
North Chicago Ry., Chicago.

Q.—Why was Dewey so successful at Manila?

A.—Because of the most thorough preparation covering a long period of years of both men and ships.

A Chapter on Experience and Skill.

Q.—Were not the Spaniards as brave as Dewey and his men?

A.—Possibly so, but they lacked the thorough training and drill which is necessary to make a marked success in any direction.

EVERYONE KNOWS THAT A PERFECT MACHINE—

whether it be a Locomotive, a Steam Engine, a Man-of-War, or a modern Trolley Car —must be the result of careful and painstaking effort directed by a high order of engineering skill.

We have had the long experience.

We have the trained men to do the work.

We have the best special machinery and the best material the market affords.

We have developed a complete system of both Single and Double Trucks.

We are prepared to fulfill every possible requirement.

Our methods and workmanship have never been questioned by anyone using Our Trucks.

CORRESPONDENCE SOLICITED

Q.—When did the Peckham Company begin to build trucks?

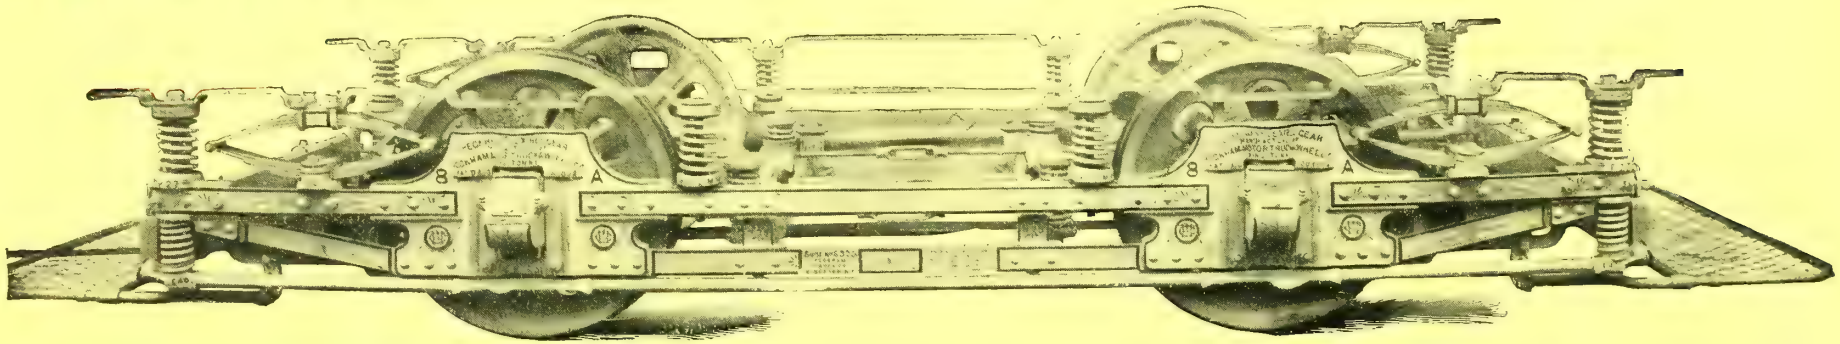
A.—At the time that electricity was first used as motive power.

PECKHAM TRUCK COMPANY,

26 Cortlandt St., - New York.

Works, Kingston, N. Y.

Q.—Why are Peckham Trucks known the world over?

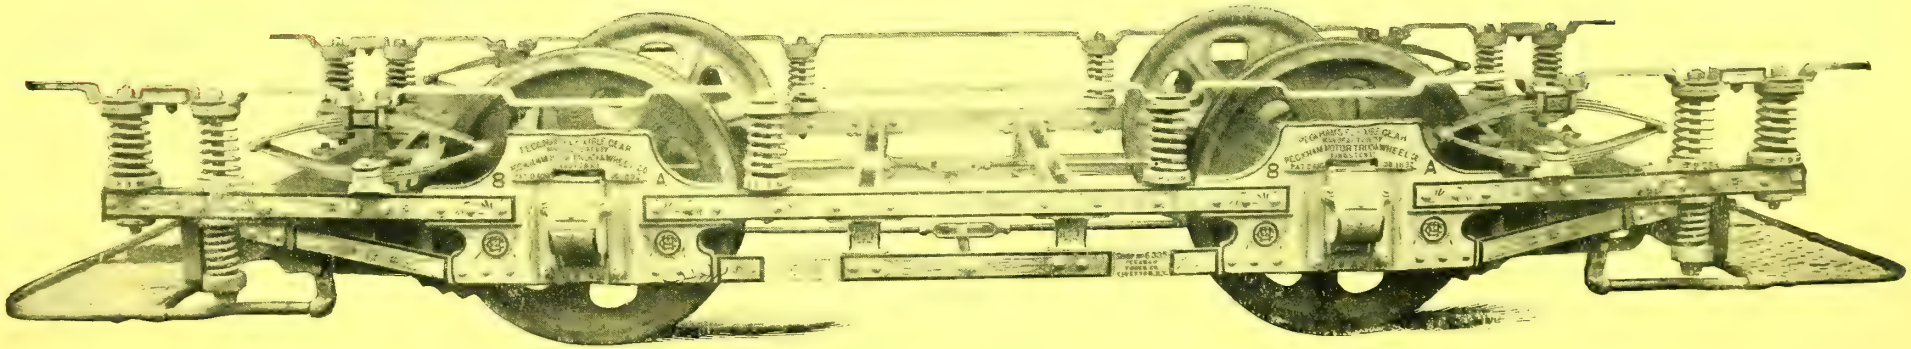


A.—Because more than TWELVE THOUSAND Peckham Trucks are in use in America and Europe, and are giving entire satisfaction.

PECKHAM'S Counter-balanced Cantilever Extension Trucks.

ESPECIALLY ADAPTED FOR "HIGH SPEED" AND "DOUBLE-DECKED" CARS.

STANDARD,

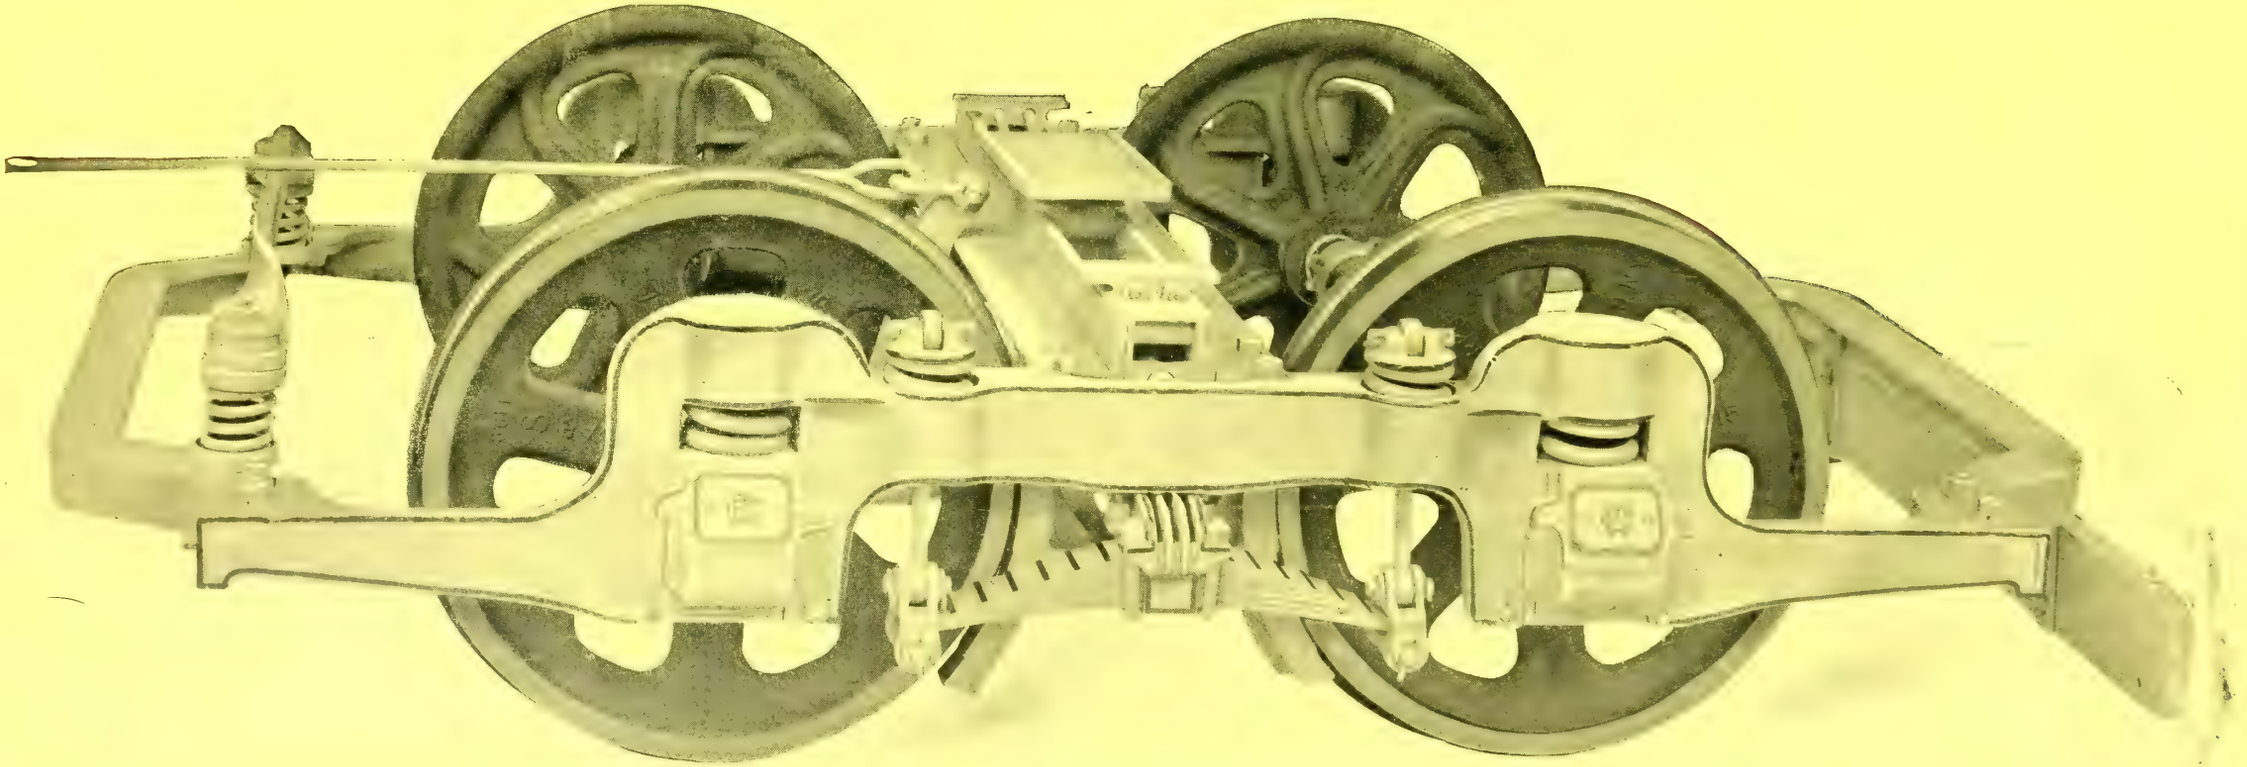


Designed for 18 and 20 feet closed, and 28 to 30 feet open cars.

EXTRA LONG

"BROADWAY" STANDARD.

Designed expressly for 20 to 24 feet closed, and 28 to 35 feet open cars.



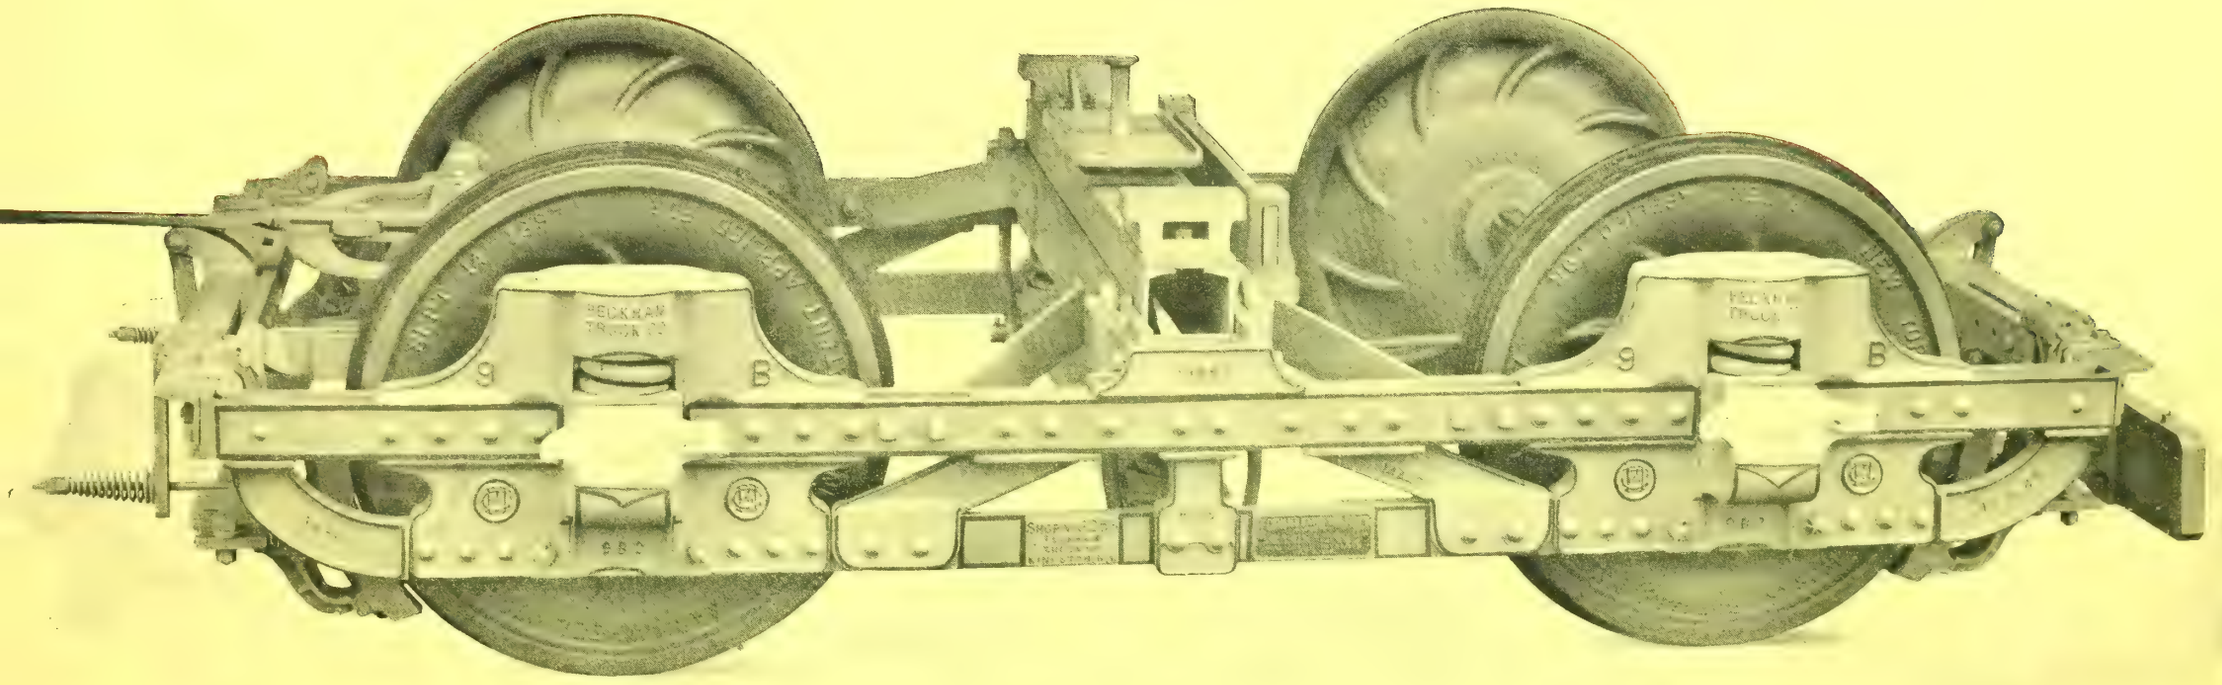
THE LONGEST AND STRONGEST SINGLE ELECTRIC TRUCKS IN USE.

OVER **10,000** IN USE IN AMERICA AND EUROPE.

See List of Electric Railways using PECKHAM'S TRUCKS, on Page 266.

PECKHAM'S ALL STEEL Short Wheel Base "Swing Bolster" Double Truck TRADE MARK 14 B-3

FOR RAILWAYS WITH SHORT RADIUS CURVES.
70 PER CENT TRACTION ON DRIVING WHEELS.
WHEEL BASE 4 ft. TO 4 ft. 6 in.
ADAPTED FOR EITHER ONE OR TWO MOTORS.



The Short Wheel Base reduces height of car bodies by allowing wheels to radiate between car sills, and requires less power on short radius curves.

Motors suspended outside of wheels give increased traction.

Equipped with inside brakes, guaranteed to be more powerful and efficient than any other in use.

PECKHAM'S "EXTRA STRONG" Center Bearing Swing Bolster Double Truck TRADE MARK No. 14 A EXTRA STRONG.

AS CONSTRUCTED FOR TWO MOTORS.

DESIGNED FOR EXTRA HEAVY "HIGH SPEED" ELECTRIC SERVICE.

AN IDEAL TRUCK FOR ANY KIND OF HEAVY OR SEVERE SERVICE.

J. M. JONES' SONS

Some Facts Regarding JONES' CARS

Distinctiveness

"State of being DISTINCTIVE."—*Webster.*

THE DISTINCTIVE FINISH, DESIGN, SYMMETRY of the WHOLE, lines of CONTOUR, etc., are so embodied in our products, that they are easily segregated. The DESIGN, COMPLETENESS and LIBERALITY of our TRIMMINGS and the COMPONENT PARTS of the car, are DISTINCTIVE. Even a WHEELBARROW has SYMMETRY—why not a STREET CAR? Some builders get the length, width and height but do not consider SYMMETRY. Without SYMMETRY there is a due loss of STRENGTH, DURABILITY and BEAUTY. There is a good reason for EVERY LINE, DIMENSION, and SWEEP in our cars.

BRILL

Snow Plows. Snow Sweepers.

SCRAPERS, COMBINATION PLOWS.....

Everything Needed for Handling Snow on Street Railways

COMBINATION PLOW

Combined Plow and Construction Car. Strong enough for the heaviest work. With four motors may be used as an electric locomotive. When stripped for summer as convenient as any construction car. In winter a perfect plow.

SNOW SWEEPER

Sweepers. Two motors for propulsion. One for driving the brooms. Independent adjustments for each end of each broom. Canvas wings prevent snow from flying. Drop forged sprocket chains. Complete housing and protection of men.

The "Eureka" Maximum Traction Trucks

FOR FAST, HEAVY, CITY AND SUBURBAN SERVICE

Can be used under Open or Closed Cars.

AMPLE TRACTION.
NO PITCHING.
STEPS LOW.

RAPID ACCELERATION.
HIGH SPEED.
NO PITCHING.

USED IN...

GLASGOW,	CAPE TOWN, South Africa
LIVERPOOL	MONTMORENCY
ST. HELENS	BUENOS ARES, South America
PARIS	IVRY PORT
BLACKBURN	DUBLIN, Ireland
BERLIN	HALLE, a/s Germany

6,100 Maximum Traction Trucks in use.

Standard Closed Car of the Metropolitan Street Railway of New York City. These Cars are mounted on our Eureka Maximum Traction Trucks.

Repairs on road bed are greatly reduced by the use of Eureka Maximum Traction Trucks. Cars mounted on them can make better headway than those mounted on four wheels. This is especially noticeable in the snows of winter.
